Journal of the Royal Society of Arts.

No. 3,026. , VOL. LIX.

FRIDAY, NOVEMBER 18, 1910.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

ONE-HUNDRED-AND-FIFTY-SEVENTH SESSION, 1910–1911.

SESSIONAL ARRANGEMENTS.

The Opening Meeting of the One Hundred and Fifty-Seventh Session was held on Wednesday evening, the 16th of November, when an address was delivered by SIR JOHN CAMERON LAMB, C.B., C.M.G., Vice-President and Chairman of the Council. (See pp. 7–15, below.)

PAPERS TO BE READ BEFORE CHRISTMAS.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

NOVEMBER 23.—SIR HENRY H. CUNYNGHAME, K.C.B., "Methods of Detecting Fire-Damp in Mines."
" 30.—CAMPBELL P. OGILVIE, "Argentina from a British Point of View."

DECEMBER 7.—VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., "The Panama Canal in 1910." Sir William H. White, K.C.B., LL.D., Sc.D., F.R.S., in the Chair.

" 14.—REGINALD A. SMITH, B.A., F.S.A., "A New View of Roman London."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock:—

NOVEMBER 29.—A. MONTGOMERY, M.A., F.G.S., "The Progress and Prospects of Mining in Western Australia." Admiral Sir Frederick George Denham Bedford, G.C.B., late Governor of Western Australia, in the Chair.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock:—

DECEMBER 15.—ROBERT FELLOWES CHISHOLM, F.R.I.B.A., F.S.A., "The Taj Mahal and its Relation to Indian Architecture."

PAPERS TO BE READ AFTER CHRISTMAS.

HORACE M. WYATT, "Motor Transport in Great Britain and the Colonies."
PHILIP JOSEPH HARTOG, M.A., B.Sc., "Examinations and their bearing on National Efficiency."
J. C. MEDD, "The Dutch Labour Colonies."
CYRIL DAVENPORT, "Illuminated Manuscripts."
GEORGE A. STEPHEN, "Modern Machine Bookbinding."
PROFESSOR J. WERTHEIMER, B.Sc., B.A., "Water Finders."
CAPTAIN A. J. N. TREMEARNE, "Some Nigerian Head-hunters."
HON. SIR RICHARD SOLOMON, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "South Africa before and after the Union."
F. DOUGLAS OSBORNE, M.Inst.M.M., "The Tin Resources of the Empire."
REGINALD MURRAY, "Indian Banking."
R. A. LESLIE MOORE, I.C.S. (retd.), "Indian Superstitions."
CAPTAIN R. MUIRHEAD COLLINS, C.M.G., "Australia and her Resources."
FRANK M. ANDREWS, "Architecture in America."
ARTHUR CHARLES DAVIS, F.C.S., Assoc.Inst.C.E., "The Manufacture and Testing of Portland Cement."
GEORGE B. HEMING, "Art Education in Jewellery and Goldsmithing."
COLONEL CHARLES EDWARD CASSAL, V.D., F.I.C., "The Adulteration of Food."
DR. LEONARD HILL, F.R.S., "Caisson Sickness and Compressed Air."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

January 19, February 9, March 16, April 27, May 25.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

January 31, February 28, April 4, May 9.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Industrial Pyrometry." Four Lectures. November 21, 28, December 5, 12.

LECTURE I.—NOVEMBER 21.—Early attempts to measure high temperatures. Newton's researches—Wedgwood's pyrometer—Early forms of thermo-electric pyrometers—Modern standards of temperature—Calibration of pyrometers—

Uses of Pyrometers in the manufacture of pottery, glass, iron and steel, coal-gas, etc.—Fusion pyrometers—Calorimetric or water pyrometers.

LECTURE II.—NOVEMBER 28.—Laws of thermo-electricity—Thermo-electric pyrometers of Le Chatelier and Roberts-Austen—Temperature indicators—Recorders, ink and photographic—Arrangement of a number of pyrometers centrally controlled—Determination of the critical points of steel—Application to hardening and tempering—Limits of use.

LECTURE III.—DECEMBER 5.—Laws of resistance to electricity—Siemens' resistance pyrometer—Callendar's pyrometer—Principles of resistance measurement—Temperature indicators for resistance pyrometers—Callendar's recorder—Northrup's recorder—Special uses and limitations of resistance pyrometers.

LECTURE IV.—DECEMBER 12.—Radiant energy—The "fourth-power" law—Laws of Wein and Planck—The Féry radiation pyrometers and indicators—The Holborn-Kurlbaum optical pyrometer—Wanner's pyrometer—Other optical pyrometers—Special uses of radiation pyrometers in pottery manufacture and work at very high temperatures.

FREDERICK WEDMORE, "Etching": 1. "The Old Masters"; 2. "Modern Etching." Two Lectures.

January 23, 30.

PROFESSOR ADRIAN J. BROWN, M.Sc., "Brewing." Four Lectures.

February 6, 13, 20, 27.

PROFESSOR J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

March 6, 13, 20, 27.

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal, its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

JUVENILE LECTURES.

Wednesday afternoons, January 4 and 11, 1911, at 5 o'clock:—

PROFESSOR ARTHUR MASON WORTHINGTON, C.B., M.A., F.R.S., "A Study of Splashes, conducted by the aid of Instantaneous Photography." Two Lectures.

CONVERSAZIONE.

The Annual Conversazione of the Society will be held about the middle of June, 1911. Each member is entitled to a card for himself, and one for a lady.

PROCEEDINGS OF THE SOCIETY.

THE SOCIETY was founded in 1754, and incorporated by Royal Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom: and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department of science in connection with the Arts, Manufactures, and Commerce of this country." In 1908 the Society was granted the privilege of adding "Royal" to its title.

The Session commences in November and ends in June.

Ordinary Meetings.—Meetings are held every Wednesday evening during the Session, at which papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed.

Indian Section.—This Section was established in 1869, for the discussion of subjects connected with our Indian Empire. Six or more Meetings are held during the Session.

Colonial Section.—This Section was formed in 1874 under the title of the African Section, for the discussion of subjects connected with the Continent of Africa. It was enlarged in 1879, so as to include the consideration of subjects connected with our Colonies and Dependencies. Four or more Meetings are held during the Session.

Cantor Lectures.—These Lectures originated in 1863, with a bequest by the late Dr. Cantor. Several Courses are given during the Session, each Course consisting of two or more Lectures. The Lectures deal with the latest applications of Science and Art to practical purposes, and are, as far as possible, experimentally illustrated.

Howard Lectures.—The bequest of Mr. Thomas Howard (1872) is now devoted to occasional courses of Lectures on motive power and its applications.

Shaw Lectures.—Under the Shaw bequest Lectures on Industrial Hygiene are given from time to time.

Aldred Lecture.—The bequest of the late Dr. Aldred has been devoted to the establishment of an Annual Lecture.

Cobb Lectures.—Funds have been provided for an occasional Lecture in memory of the late Mr. Francis Cobb.

Juvenile Lectures.—A Short Course of Lectures, suited for a Juvenile audience, is delivered to the children of Members during the Christmas holidays.

Admission to Meetings.—Members have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted by signing their names. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor and other Lectures. Books of tickets for the purpose are supplied to the Members, but admission can be obtained on the personal introduction of a Member. For the Juvenile Lectures special tickets are issued.

Journal of the Royal Society of Arts.—The *Journal*, which is sent free to Members, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures and Commerce.

Examinations.—Examinations, founded in 1853, are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person. The subjects include the principal elements of Commercial Education and Music. Full particulars of the Examinations can be had on application to the Secretary.

Library and Reading-room.—The Library and Reading-room are open to Members, who are also entitled to borrow books.

Conversazioni are held, to which Members are invited, each Member receiving a card for himself and a lady.

Membership.—Candidates for Membership are proposed by Three Members, one of whom, at least, must sign on personal knowledge; or are nominated by the Council.

The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day preceding election; or a Life Subscription of Twenty Guineas may be paid. There is no Entrance Fee.

CALENDAR FOR THE SESSION.

The following is the Calendar for the Session 1910–1911. It is issued subject to any necessary alterations :—

The Annual General Meeting will be held at Four o'clock.

The Juvenile Lectures will be given at Five o'clock.

NOTICES.

"INDUSTRIAL ENGLAND IN 1754."

In accordance with a resolution passed by the Council* the Paper read before the Society on April 20th, 1910, by the Secretary, has now been published in book form, with corrections and additions, under the title "Industrial England in the Middle of the Eighteenth Century." The price of the book is 5s. net, and copies may be obtained of the publisher, Mr. John Murray, Albemarle-street, London, W.

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Thursday afternoon, the 10th inst. Present:—

Sir William Lee-Warner, K.C.S.I. (Chairman of the Committee), Sir John Cameron Lamb, C.B., C.M.G. (Chairman of the Council), Sir Arundel T. Arundel, K.C.S.I., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., William Coldstream, B.A., Sir Steyning William Edgerley, K.C.V.O., C.I.E., James Fairbairn Finlay, C.S.I., Krishna Govinda Gupta, C.S.I., Sir Philip Perceval Hutchins, K.C.S.I., Henry Luttman-Johnson, Sir Patrick Playfair, C.I.E., Sir John David Rees, K.C.I.E., M.V.O., M.P., Carmichael Thomas, Thomas H. Thornton, C.S.I., D.C.L., Alexander Falconer Wallace, Sir Raymond West, K.C.I.E., M.A., LL.D., Sir James Wilson, K.C.S.I., with S. Digby, C.I.E. (Secretary of the Section).

PROCEEDINGS OF THE SOCIETY.

FIRST ORDINARY MEETING.

Wednesday, November 16th, 1910; Sir John Cameron Lamb, C.B., C.M.G., Vice-President and Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Aitken, William, 17, Church-street, Dumbarton, N.B.

Anderson, Rev. James Forrester, B.D., B.Sc., B.A., St. John's Presbyterian Church, Port Louis, Mauritius.

Anderson, Robert, 8, Esplanade East, Calcutta, India.

Andrews, Frank M., Metropolitan Building, New York City, U.S.A.

Archibald, Captain James F. J., 1053, Marbridge Building, Herald-square, New York City, and Army and Navy Club, Washington, D.C., U.S.A.

Arnold, Felix, Ph.D., A.B., 824, St. Nicholas-avenue, New York City, U.S.A.

Arnot, David, c/o Messrs. Wilson, Sons & Co., Rio de Janeiro, Brazil.

Barrow, John, 26, Old Broad-street, E.C.

Bethune, J. T., 406, Eastern Townships Bank Building, Montreal, Canada.

Biswas, Jatindra Kumar, M.A., 23, Crematorium-street, Entally, Calcutta, India.

Blair, David Ker, M.I.Mech.E., 11, Grey-street, Wellington, New Zealand.

Blamires, Joseph, Bradley Lodge, Huddersfield.

Brown, Percy, 28, Chowringhee, Calcutta, India.

Burlton, C. H. B., Highmore-house, Hereford.

Chessum, Roland B., Woodbury, Enfield, N., and 7A, South-place, E.C.

Clifford, Charles, Chudleigh, Halfin-road, Rangoon, Burma.

Clutton, Miss Maria, 5, Chester-place, Regent's-park, N.W.

Davidson, David, Station-house, Galashiels, Scotland.

Day, Miss Ruth M., 15, Taviton-street, W.C.

Deb, Atindra Krishna, 4, Shampuker-lane, Calcutta, India.

Dickinson, H. P., 807, Majestic Building, Denver, Colorado, U.S.A.

Duncan, Professor Robert Kennedy, 4715, Wallingford-street, Pittsburgh, Pennsylvania, U.S.A.

Dunnington, Professor Francis P., University of Virginia, Charlotteville, Virginia, U.S.A.

Fauth, J., Messrs. Zaretzky, Bock and Co.'s Rice Mills, Dawbong, Rangoon, Burma.

Ferguson, James R., Rooms 314-315, Birk's Building, Montreal, Canada.

Fripp, R. MacKay, 429, Pender-street West, Vancouver, British Columbia, Canada.

Gage, Professor Simon Henry, Stimson-hall, Cornell University, Ithaca, New York, U.S.A.

Gajjar, Professor T. K., M.A., B.Sc., F.C.S., Techno-Chemical Laboratory, near Girgaum, Tram Terminus, Bombay, India.

Ganguly, Ananda Lal, Khalia P.O., Faridpur District, East Bengal, India.

Garnham, James Coote, 132, Upper Thames-street, E.C., and Holmleigh, 3, Fountayne-road, Stoke Newington, N.

Garrett, Thomas Richard Henry, M.A., c/o Messrs. G. Gillespie and Co., Rangoon, Burma, and 16, Queensland-road, Boscombe, Hants.

Giangirji, Raja Bahadur Narsingirji, Begum Bazaar, Hyderabad, Deccan, India.

Gilbert-Wood, Clarence, 5 and 3, Arundel-street, Strand, W.C., and Bertwood, Wimbledon, S.W.

Gill, George T. S., 37, Lancaster-road, Hampstead, N.W.

Greenwell, George Harold, c/o Messrs. Kilburn, and Co., 4, Fairlie-place, Calcutta, India.

Gregg, William Henry, M.D., 135, Cambridge-place, Brooklyn, New York, U.S.A.

Hazard, Hon. Rowland Gibson, A.M., Holly-house, Peace Dale, Rhode Island, U.S.A.

Hollingsworth, John Burton Lee, D.V.S., M.D.C., 105, Cambridge-street, Ottawa, Canada.

* See Report of the Council, *Journal*, vol. lviii., p. 753.

Horne, Rev. Joseph White, M.A., Ivy-house, High-street, Highgate, N.
Hotson, John Ernest Buttery, I.C.S., Secretariat, Bombay, India.
Huber, E. H., 510, Quincy Building, Denver, Colorado, U.S.A.
Inglis, F. A. S., c/o O. H. McCowan, LL.B., Y.M.C.A., Rangoon, Burma.
Innes, Charles, B.Sc., Assoc.M.Inst.C.E., c/o Messrs. T. Cook and Sons, Rangoon, Burma.
Jacobs, J. Warren, Waynesburg, Pennsylvania, U.S.A.
Katayama, Tokuma, Bureau of Works of the Imperial Household Department, Tokio, Japan.
Keay, Lyle, The Mercantile Bank of India, Calcutta, India.
Knight, Joseph, Southfields, Bury, Lancashire.
Lay, Harry Arthur, 45, Hanley-road, Hornsey-rise, N.
Lee, Professor Edwin, B.S., A.M., M.Sc., Meadville, Penn., U.S.A.
Leggatt, Percy Scott, 15, Marine-parade, Lowestoft.
Levene, Dr. P. A., 230, West 139th Street, New York City, U.S.A.
Lubbock, Hon. John Birkbeck, 15, Lombard-street, E.C.
McBride, James H., M.D., Pasadena, California, U.S.A.
Mead, Marvin Hulst, 382, River-drive, Passaic, New Jersey, U.S.A.
Mitchell, Francis James, Srinagar, Kashmir State, India.
Morris, William Hardwicke Grant, A.M.I.Mech.E., Cairo Water Works, Rod El Farig, Egypt.
Mower, Charles Huson, 147, Queen Victoria-street, E.C., and 14, Lower Berkeley-street, W.
Muthukoya-Thangal, Khan Bahadur P.M., Calicut, India.
Nath, Rai Sahib Dewan Amar, Chief Minister to His Highness the Maharaja, Jammu and Kashmir State, India.
Nichalls, J. Mayne, The Nitrate Railways Co., Ltd., Iquique, Chili, South America.
O'Callaghan, T. P. M., Gauhati, Assam, India.
Peart, Arthur Wellesley, B.A., The Maples, Burlington, Ontario, Canada.
Percy, Norman Crook, Assoc.M.Inst.C.E., Byculla Ironworks, Bombay, India.
Pitt, George Earley, B. ès L., Knutsford, Cadbury-road, Moseley, Worcester.
Poats, Thomas Grayson, Clemson Agricultural College, Clemson College, South Carolina, U.S.A.
Powell, Henry Richard, South Lawn, Bickley, Kent.
Prentice, Thomas Theophilus, Assoc.M.Inst.C.E., Empresa del Agua, Lima, Peru, South America.
Pyne, Herbert Barrington, Assoc.M.Inst.C.E., 370, Calle Cangallo, Buenos Aires, Argentine.
Richards, H. W., Brookside, Beverley-road, Barnes, S.W.
Robinson, James, Assoc.M.Inst.C.E., Bhagalpur, Bengal, India.
Roe, Richard Dartnell Tennant, Assoc.M.Inst.C.E., Sir John Jackson (Chile), Ltd., Ferro Carril Arica La Paz, Arica, Chile, South America.
Rohrer, C. W. G., M.A., M.D., B.Sc., Baltimore, Maryland, U.S.A.
Sahasrabudhe, Rao Sahib Ganesh Nagesh, Ellichpur, Amraoti District, Berar, Central Provinces, India.
Seligmann, Albert, 49, Fitzjohn's-avenue, N.W.
Sharrock, Charles William, Dorincourt, Grays, Essex.
Sheoparshad, Rai Bahadur Lala, Rais and Honorary Magistrate, Chandni Chowk, Delhi, India.
Shukul, Rai Bahadur Pandit Bishun Dutta, Sehora-road (E.I. Railway), Jubbulpore District, Central Provinces, India.
Smeaton, Major Charles Oswald, R.A., United Service Club, Pall Mall, S.W.
Smith, William Charles Ernest, M.Inst.C.E., The Nitrate Railways Co., Iquique, Chile, South America.
Spoor, Stanley M., 59, Chancery Lane, W.C.
Stewart, Captain Thomas, V.D., K.I.H., 1, Thackeray-road, Alipore, Calcutta, India.
Stowell, Herbert, 10, Morley-road, Southport.
Taylor, Edward, 17, Thurleigh-road, Wandsworth-common, S.W.
Watkins, Stephen, Assoc.M.Inst.C.E., Ottoman Railway, Smyrna, Turkey in Asia.
Wills, J. Lainson, F.C.S., 133, Midwood-street, Brooklyn, New York, U.S.A.
Woodhouse, Thomas, Briarcliffe, Wormit, near Dundee.
Yearsley, Walter A., Rosador, St. Anne's-on-Sea, Lancashire.
Zizold, Alfredo, Lima, Peru, South America.

The CHAIRMAN delivered the following—

ADDRESS.

At the outset I desire to express my sense of the honour which my colleagues have conferred on me, and to say that it is only in reliance on their forbearance and kindly support that I can hope to perform the duties of the office to which they have called me.

One of the first of these duties is to deliver an address. It has not been easy for me to choose a subject, because most of the questions in which I am interested are controversial or otherwise unsuitable. There is no necessity to describe the work of last session, as that has been admirably done in the annual report prepared by our secretary; and I do not think that any of our affairs demand special attention—unless it be the inadequacy of this building for the work we have to do in it. The conviction of that inadequacy is growing, and promises soon to overcome any reluctance to leave this time-honoured place, where Dr. Johnson spoke and Goldsmith tried to speak. We must hope that powerful, willing, and influential friends will be found to support

us in any measures we may find it prudent to take with a view to obtain better accommodation.

With regard to the coming session there is promise of an interesting and useful series of papers. Before Christmas Sir Henry Cunynghame, whose competence to deal with the subject is known to all, will read a paper on "Methods of Detecting Fire-Damp in Mines"; and his paper will be followed by papers on "The Progress and Prospects of Mining in Western Australia," "Argentina from a British Point of View," "The Panama Canal in 1910," "A New View of Roman London," and "The Taj Mahal and its Relation to Indian Architecture." For the meetings after Christmas the list already contains twenty-seven papers and lectures, of which I mention one—namely, "Dutch Labour Colonies," by Mr. Medd—because it affords me the occasion to say that six years ago Mr. Medd read a valuable paper here on "Agricultural Education," and I hope he may be induced to read another. The Society has taken a leading part in fostering commercial education, and might take an equally honourable part in promoting the kind of education which would fit the rural population for rural occupations and keep them on the land. It seems scarcely likely that those who have become accustomed to town life will return to the land; but if the young people there, instead of being made into clerks, were trained to become masters and mistresses of the arts and crafts which belong to prosperous village life, they might, perhaps, be induced to stay where they are. The first necessity is a sound public opinion on the subject, and the Society, by giving publicity to such papers as that which was read by Mr. Medd in 1904 may do much towards forming it.

On previous occasions you have had described to you the history and objects of our Society, its relation to other societies, and the part it has taken in bringing some of them into being. Since 1754, when it was founded and became one of a trio with the Royal Society and the Society of Antiquaries, so many societies have come on the scene that you might be pardoned if you thought there could no longer be any necessity to maintain one like ours. The list of other societies in London—I use the word "societies" in its widest sense—does indeed convey the impression that, by the experts in those societies, arts, manufactures and commerce must be completely and exhaustively looked after in all their ramifications. But I venture to say that, so far from rendering ours unnecessary, the existence of such societies increases the need for its maintenance in vigour and efficiency, and calls for strenuous efforts to promote its prosperity. For what do we see in many of them, admirable as they are? We see specialists, working together in their own special sphere, not mingling in their work with the general public or even with other kinds of specialists; we see tests and barriers set up and terms and expressions used which are hard to be understood; we see methods adopted which, however natural and necessary, must tend to the creation of a class or classes apart. The merit of our Society is that it excludes no one, creates no class, sets up no tests, barriers, or distinctions; that it brings specialists and experts of all kinds into fellowship and co-operation, links them with men of affairs, and brings them all and their work into relation with an appreciative public and with the current life of the nation. Surveying the field of human activity it turns to all classes and conditions of men and says, in the words of Pope in his "Essay on Man":—

> Let us . . . .
> Expatiate *free* o'er all this scene of man;
> A mighty maze! but not without a plan;
> . . . .
> *Together* let us beat this ample field,
> Try what the open, what the covert yield.

It is impossible for me, however, to "beat this ample field." I must limit myself to something which will not hold you long; and the suggestion has been made that I should speak to you on "Telegraphs." My old friend and colleague, Sir William Preece, and others, have described and illustrated this subject, and I think they must have told nearly all there is of it in science, in history, or in anecdote. About its administrative side, with which I am more familiar than with any other, many interesting things might, no doubt, be told; but the best of them are highly controversial, and therefore barred. I propose, then, with your permission, to describe how from time to time telegraphs have come within the sphere of our Society. That is a field, I think, which has not been beaten before. I do not propose to carry the description further down than to sixpenny telegrams. After that everything must be well within your recollection. Moreover, by limiting my address in this way, I hope to escape the charge of being tedious, and, in any case, I shall happily avoid the question of the policy of the State in regard to telephones.

The first mention of telegraphs in the Proceedings of the Society was in 1805, when a silver

medal and ten guineas were awarded to Joseph Davis for a "Night and Day Telegraph." It was not an electric telegraph, but a semaphore, with seven shutters for day work and seven lamps for night. Whether it ever came into use I cannot ascertain. The Admiralty were using a semaphore with six shutters; and, eleven years later, they adopted Sir Home Popham's mast with two arms which, in this country, seems to have superseded every other form. In the very year in which they did this, a member of our Society, Mr. (afterwards Sir) Francis Ronalds, was experimenting in his garden at Hammersmith* with an electric telegraph, and he afterwards recorded his success in the following words:—"The result seemed to be that that most extraordinary fluid or agency, electricity, may actually be employed for a more practically useful purpose than the gratification of the philosopher's inquisitive research . . . that it may be compelled to travel . . . many hundred miles beneath our feet . . . Why has no serious trial been made of the qualifications of so diligent a courier? . . . Why should not our Kings hold councils at Brighton with their Ministers in London? . . . Why should our defaulters escape by default of our foggy climate? . . . Let us have electrical conversazione offices, communicating with each other all over the kingdom." But it was not until 1843 that the electric telegraph came before the Society. On the evening of May 17th in that year, "Cooke and Wheatstone's improved practical electric telegraph," as used on the Great Western Railway, was described in this room and illustrated by a complete telegraph at work, the manipulators being two of the young men who were daily working the telegraph on the Blackwall Railway. On the table there were diagrams, specimens of wire, models of winding and drawing apparatus, Cooke's detector for the location of faults, and models of posts. Already there were electric telegraphs on the Manchester and Leeds and Edinburgh and Glasgow Railways, as well as on the Blackwall and the Great Western, and generally they were underground. Cooke's experimental line laid underground from Euston to Camden Town in 1837, often called the "fossil telegraph," was embedded in wood, and later telegraphs were laid in iron tubing; but lofty poles with glass or earthenware insulators were coming into vogue; and the model posts shown on the table represented the beginning of that network of aerial telegraphs which now spreads over the land, imparting a human interest to roads and solitary wastes, and comforting the lonely dweller or traveller with the thought that he is not cut off from his fellow men.

* Ronalds's house here was afterwards occupied by William Morris, the poet.

At this time there was apparently no thought of submarine telegraphy; but a discovery was made which was to become of incalculable value in the manufacture of submarine cables. On March 1st, 1843, Surgeon Montgomerie submitted to the Bengal Medical Board the first specimens of gutta-percha of which there is any historical record. In the summer of the same year he sent specimens to this Society, and the Society's Committee of Chemistry, Colonies and Trade investigated the qualities of the material and took practical steps to bring it into use.

In 1845, the Secretary, Mr. Whishaw, having read here a paper describing it and shown articles which he himself had made out of it, Dr. Montgomerie was awarded the gold medal of the Society in recognition of the great importance of his discovery. The work of the Society led directly to the importation of gutta-percha as an article of commerce, and to its being shown at the Great Exhibition of 1851. Not only so, but it led to its being used for the insulation of telegraphs, for it was here, on the occasion of Mr. Whishaw's paper, that Mr. William Siemens heard of the newly-discovered substance and obtained pieces of it for transmission to his brother, Werner Siemens, of Berlin, who was the first to show how it could be used for covering telegraph wires.

In 1851 a Mr. George Little described an improved double-needle instrument, in which the needles were not pivoted in the middle, but were suspended from what he called a "reservoir of magnetism."

Then nothing happened so far as the Society was concerned until February, 1853, when a project for a new telegraph to the Continent was brought before the Society. The brothers Brett had in 1851 laid the first submarine cable of the world between Dover and Calais, and cables had subsequently been laid to Ireland and Belgium, as well as for short distances elsewhere. A company, called the International Telegraph Company, was now formed, "with the view of constructing a submarine telegraph" to Holland. There were to be six conductors and they were to be laid from Lowestoft to Scheveningen. The description given to the Society proceeded as follows:—

"In all former submarine cables, where it was intended to employ several wires, they have been collected together under one coating of stout iron wire, the whole, when completed, bearing the

appearance of an iron rope, of a diameter varying from 1½ ins. to 2 ins. In the present instance the distance to be crossed is so great, that an entire cable, containing the six wires it is proposed to lay down, would weigh above 1,400 tons, which would cause much inconvenience in the operation of laying down. From this and other reasons, the Company's engineer, Mr. Edwin Clarke, has been induced to adopt a new system, and form each wire into a distinct cable by itself; thus between England and Holland there will be laid six independent submarine cables, each of them containing one wire. The advantage of this method in the case of any accident is great, as the faulty rope can be immediately recognised, and overhauled and repaired with facility, which, with a heavier line, if possible at all, would certainly be an operation of considerable difficulty and time. These six cables will be laid down in succession, one after the other, during the ensuing spring. The last four or five miles on either side, being the portion most subjected to danger, will consist of a compound cable, composed of six strands of the single wire cable twisted into one, the strength and weight of which—twelve tons per mile—will act as a safeguard against vessels inadvertently anchoring on the line, or any mischief that may be attempted."

The project was duly carried out, with this modification however, that only four separate "ropes" or cables were laid. A promise was made that a detailed account of the work should be presented to the Society, but the promise was never performed. People do not like to record their failures, and this was a failure. The cables had a curious later history. To a large extent they were recovered from the bottom of the sea, repaired, made up into heavy cables of from four to seven conductors and used again. In 1862 four pieces were twisted together and laid as one cable in Milford Haven and seven were laid across Waterford Harbour, while four years later six were twisted round a central core of indiarubber-covered wire and made into a cable with seven conductors, which was laid from Portpatrick to Whitehead, a distance of twenty-three nautical miles.

In June of 1853 the Society published a communication describing the labours of that great pioneer of telegraphy, Dr. O'Shaughnessy, in promoting, under the sanction and encouragement of the Governor-General and Court of Directors, a wide and rapid development of telegraphs in British India, and showing India in the van of progress with a State system of telegraphic communication.

This was also a year of hope—but only of hope—for direct telegraphic communication with America. In view of the difficulty of telegraphing through a long cable it had been proposed to reach that continent by a series of cables starting from Scotland and extending to the Orkneys and Shetlands, and thence to the Faroe Isles, Iceland, Greenland, and Labrador. When this proposal for some reason fell through, it was reported to the Society, on the authority of Robert Stephenson, the engineer, that, after all, a direct cable might be successful if it were furnished with two conductors forming a metallic circuit. This was hailed by the Society as giving promise of "oceanic telegraphs encircling the whole earth and bringing all parts of it into instantaneous communication with each other." But, as you know, there were many disappointments in store: the metallic circuit across the Atlantic was not tried; the attempts to establish telegraphic communication with America in 1857, 1858, and 1865, all in one way or another came to nothing; and not until 1866 was success achieved. So far as I am aware, metallic circuits were never used in submarine cables until they were adopted in 1891 for the telephone service to Paris.

The year 1853 saw wireless telegraphy brought before the Society. This was in a note describing the experiments of Mr. Lindsay, of Dundee, a teacher of mathematics, who delivered lectures in Glasgow, and showed how the electric telegraph could be worked through a wireless gap with water as the conducting medium. This, you will see, was wireless telegraphy, but very different from the wireless telegraphy of to-day.

In March, 1857, the Society was informed of an instrument invented by Dr. Bernstein, of Berlin, by which two messages could be telegraphed simultaneously on the same wire; and this was probably the origin of "diplex," if not of "duplex," telegraphy.

In October of the same year the Society published extracts from a letter of Professor Morse and the official reports of Mr. (afterwards Sir) Charles Bright, describing the breaking of the first Atlantic cable as it was being paid out from the United States frigate *Niagara*. This failure and a failure in the Mediterranean led a Mr. De la Haye to propose a new method of submerging deep-sea cables. As described in our *Journal* of October 27th, 1857, his proposal was that the cable should be coated with a soluble compound which would keep it floating for a time on the surface of the water. He calculated that about five miles of cable could always be held up by this means in the wake of the cable ship, and he thought that, as the compound dissolved, the cable would gradually descend in an almost horizontal position instead of in a nearly

vertical one. In this way liability to break would be reduced to a minimum. There is no record of a trial of Mr. De la Haye's plan, or explanation of the means by which he proposed to make the soluble compound adhere evenly and keep its place when the cable was coiled in the hold or when, with several turns round the cable drum, it was paid out over the cable sheaves.

A plan for connecting the police and fire-brigade stations in London by the electric telegraph was brought before the Society in December, 1857, by Mr. (afterwards Sir) Sydney Waterlow. He was well qualified to offer advice, not only because of his practical interest in everything affecting the comfort and safety of the public, but because he had already caused the three business premises of his firm, in Birchin Lane, London Wall, and Parliament Street, to be connected by private wires, and had proved how greatly they facilitated business and what a saving in time and labour they brought about.

On April 21st, 1858, Mr. (afterwards Sir) William Siemens read an important paper on "The Progress of the Electric Telegraph" from the earliest times. Mr. (afterwards Sir) William Grove, Q.C., who became celebrated as a judge and as a man of science, was in the chair, and there was an animated discussion in which Mr. Highton (the inventor of the Highton single-needle instrument) and Mr. Varley took part. Mr. Siemens mentioned the work in 1728 of Stephen Gray, a pensioner of the Charter House; of Lesage, of Geneva; of Lomond, the Frenchman; of Galvani and Volta; of Oersted, Faraday, Ampère, and Morse; of Gauss and Weber; and of Cooke and Wheatstone. He discussed the use of gutta-percha as an insulating material and gave his opinion as to the best design to adopt for submarine cables; prophesied the supersession of double and single-needles by Morse printers, and a general reversion to underground telegraphs; and hinted at a possible use of aluminium, instead of copper, for the conductors of deep-sea cables. At that time there was no inkling that Morse printers themselves would be superseded by Morse sounders—one of the most remarkable developments from complication to simplicity that has ever been seen—or that insulation by a combination of air and paper would come into use, a form of insulation which alone has rendered feasible a wide resort to underground telegraphs. As to the conductors of deep-sea cables, copper, as you all know, still holds the field. In the time at our disposal it is impossible to go further through the details of this able paper; but those of you who have watched the working of a modern single-needle instrument may be interested to learn that the needle of Gauss and Weber, which Mr. Siemens saw when he was a student at Göttingen in 1833, weighed 100 lbs., was suspended by silk from the ceiling, and had to be observed—for its delicate movements to the right or to the left—through a telescope. In the discussion Mr. Highton foreshadowed that system of codes which has caused not a little anxiety to submarine cable companies from time to time. He declared that he had already devised a code of his own. What it was I do not pretend to understand; he said it contained "800,000,000 times 2,000,000 preconcerted messages," and that the messages "did not occupy one side of half a sheet of foolscap, and each would not occupy more than twelve seconds in transmission." Truly a case of *multum in parvo.*

There was a memorable meeting here on April 13th, 1859, when a paper was read describing the printing telegraph of Professor David Hughes, and a method he had devised to cure cracks in the gutta-percha of submarine cables by a viscous fluid which was to be applied to the copper conductor, and was to ooze automatically through the cracks and harden. This method came to nothing, but the printing telegraph conquered Europe, and still holds sway as one of the most efficient instruments in daily use. What a meeting to stir the pulse of a telegraph man! In the chair sat William Fothergill Cooke; among the men present and admitted that night to membership for the first time was Cromwell Fleetwood Varley; and beside him was the genial Hughes himself, who was to add to his laurels at a later date by inventing the microphone.

I trust you will not blame me for having lingered over these early days. I will now proceed at a more rapid rate.

Land telegraphs had been gradually spreading over the civilised parts of the world, and schemes of submarine telegraphy were multiplying. The *Journals* of the Society presented reports and discussions on the making, laying, and repairing of submarine cables, on the types of cable best adapted to particular cases, and on the instruments which might be used to overcome the difficulties experienced on long lines of communication. They furnished information on home, foreign, and colonial telegraph systems, and gave statistics of their growth; they gave to the world the Cantor lectures of Professor Fleeming Jenkin; they recorded the founding of the International Telegraph Union, whose object it was

to bring the telegraph administrations and companies of the world into harmonious co-operation, and to settle the terms and conditions on which they could carry on the business of international telegraphy—a Union, I may remark, which was the prerunner of the International Postal Union founded in 1874. With the exception of North America and the British Isles every country using the telegraph had placed it under government management—sometimes in conjunction with the post office and sometimes independently. In this country the question was now being publicly mooted whether it was not time that the State should buy up the undertakings of the telegraph companies, and Mr. (afterwards Sir) Edwin Chadwick, that man of untiring energy, took the lead as a member of this Society in forcing the question to an issue. Whenever a real reform affecting a government department is beginning to recommend itself to the public they may feel pretty sure that some civil servants are already at work on it behind the scenes. So it was in this case; Mr. F. I. Scudamore and Mr. F. E. Baines were at work within the walls of the Post Office. In his report presented to Parliament, Mr. Scudamore testified that as early as 1856 Mr. Baines had proposed the transfer of the telegraphs to the State; and declared that, although his proposals were not first in order of date—a Mr. Allan having made proposals in 1854—yet "they were the first which contained any practical suggestions as to the mode in which the transfer might be effected, any distinct practical statement of the advantages which might be expected to accrue from it, or any reliable data in support of the arguments advanced." This does not detract from the merit or interest of Mr. Chadwick's work, and I have no doubt that Mr. Scudamore and Mr. Baines rejoiced that such a man should be working in the same direction as themselves. On more than one occasion in later days it is certain that an officer of the Post Office would have hailed the help of a man like Chadwick and of a disinterested body like the Council of this Society. Mr. Chadwick's paper here on February 27th, 1867, had a powerful effect on public opinion and helped materially to pave the way for the telegraph legislation of 1868. He showed the advantage of concentrating in the hands of one authority the undertakings of the various companies, which, in many places, had rival offices almost side by side, but practically no facilities in the villages; which planted two or more lines of poles on a road where one would have sufficed for the requirements of the public; which charged porterage on a large proportion of the telegrams delivered, and carried the telegraph into no locality unless there was a prospect of business sufficient to pay for the rent of an office, for light and firing, for a telegraphist and for messengers. He pointed out that the Post Office had an immense number of offices already open for postal business, and that telegraph business could be transacted in such offices at less cost than in offices specially established for the purpose; that a Department of the State ought to be able to procure wayleave for its poles and wires on less onerous conditions than a private company trading for profit; that the expansion of the system which would result from its being placed under public control would foster trade and commerce, add to the comfort and security of the public, and make life in country places more tolerable and more profitable. He had well in view the subject of porterage, intimately connected as it was with delay to the messages. The charge for telegraphing a message from London to Ham, where Mr. Chadwick lived, was one shilling, but eighteenpence had always to be paid for delivery; therefore the message was delayed and the real charge was half-a-crown. All over the country there were not only cases like this, but cases much worse. How different the situation is now we all know. The only criticism, I think, to which the paper was open is that it was too sanguine with regard to the financial results of a transfer to the State. Mr. Chadwick did not sufficiently gauge the power of the railway companies, or the determination of Parliament to improve the conditions of service of the employees, while at the same time demanding ever-expanding facilities. The public cannot have it both ways; they can have a balance on the right side expressed in the manner familiar to accountants if they direct their administrators to conduct the business on commercial principles, but if they prefer to have facilities at any cost they must be content to see financial deficits. They do after all get a balance on the right side, but it is expressed in facilities and not in Arabic figures. The meeting was remarkable for a speech delivered by Mr. Scudamore himself—a speech which Mr. Chadwick described as "complete and satisfactory."

Before we pass from the year 1867 it may be well to mention that the Society's Albert medal was awarded in that year to William Fothergill Cooke and Charles Wheatstone. It seems specially appropriate that the Society should have rewarded those great inventors at the very time when it was itself taking so prominent a part in

bringing about a wide expansion of the system which they had placed at the disposal of the public.

Mr. Chadwick did not rest. In the following year he contributed to the *Journal* of the Society some powerful letters in support of the policy of transferring the telegraphs to the State; and there can be little doubt that by the publicity which it gave to these letters, as well as to the paper which Mr. Chadwick read here, the Society helped to overcome opposition and to educate public opinion. In the same year (1868) an Act was passed authorising the Postmaster-General to buy up the undertakings of the telegraph companies, and Mr. Chadwick and the Society were satisfied for the time; but the Act of the following year (1869), which conferred a monopoly on the Postmaster-General, stirred the Society afresh, and it appointed a special committee to watch the Post Office and keep it up to the mark. Apparently the work of this committee was not very arduous. In 1872 the Council of the Society broke fresh ground and began a course of pressure, which they continued for several years, in favour of the purchase of the "ocean telegraphs" and the consolidation of "the same with the internal telegraph service under the management of the Post Office." Their views were well expressed in a memorial addressed to Mr. Gladstone, who was then Prime Minister, and the memorial was followed by a letter in which the Council showed their confidence in Mr. Scudamore by proposing that he should be directed to examine the question and prepare a report for the consideration of Government. A favourable result was not possible. The telegraph department had its hands full with the management of the internal service; while to carry out the provisions of the Telegraph Acts, which left the external telegraphs outside the Postmaster-General's monopoly, it had made agreements with certain companies from which it could not set itself free. When in 1889 these agreements were approaching expiry the department lost no time in arranging with the entirely friendly Administrations of France, Belgium, Holland, and Germany for the joint ownership, joint maintenance, and joint working in each case of the cables from this country, giving effect thus far to the views of the Society. These cables were practically frontier telegraphs involving no serious international difficulties. The case was very different with the long cables touching the territories of various foreign Powers. Here the cable companies had an advantage over any State administration. They were allowed to establish offices of their own and thus to secure unity of management from end to end. No State administration could expect to be permitted to have offices and employees on foreign territory. With the frontier telegraphs an intermediate company was an obstruction; but, in the case of the long cables touching various countries, a company conferred a benefit on the public and on commerce by its singleness of system and control. The subject is too large to discuss this evening, but I mention it in order to explain that the policy recommended by the Society had relation, consciously or unconsciously, to two different cases, one complicated and controversial and the other clear and non-controversial, and that when the latter—the frontier telegraph case—came within range it was dealt with by the Post Office in a practical manner without delay.

The Society had done well, and had helped to bring about a result the importance of which it would be difficult to exaggerate. Not only was the internal system of telegraphs cheapened and expanded so as to facilitate home business in all directions, but the way was prepared for the direct management and working of the telegraphs to neighbouring States; British capital was released for investment in submarine cables; experienced British administrators were set free to devote themselves to the management of great telegraph undertakings; and the manufacture of cables by British firms was encouraged and set on an almost unassailable basis. In helping to promote the transfer of the inland telegraphs to the State the Society had done more than appeared on the surface. Submarine telegraphy was awaiting development; courageous and able pioneers had entered that field, but more capital was required and the aid of experienced administrators. By the transfer to the State both were made available, and the position which Nature and the enterprise of her people had given to this country was seized with firm hands, was defended, confirmed, and strengthened; and in a comparatively short time the United Kingdom was presented to the world as the absolute centre of telegraphic communication.

If the position has in recent times been to any degree weakened it is not the fault of the men to whom I have referred, or of their successors. Nor is it the fault of this Society.

In 1879 Sir William Preece delivered here a series of six Cantor lectures on "Recent Advances in Telegraphy"; and by the clearness and simplicity of his explanations and the success of his experiments made the subject plain to the least scientific mind. By means of these

lectures the Society performed a fresh service to the public in stimulating interest in a subject which was more and more affecting the comfort and prosperity of the nation.

Mr. Chadwick and the Society had expected that when the telegraphs were acquired by the State, the charge for an inland telegram would be reduced to 6*d*., and the same expectation was entertained by the reformers within the Post Office. But time and thought showed that it was too much to achieve at once with the means then available. The volume of additional work which it would have thrown on a new department would have been too great. The plant acquired from the companies had to be put in order, fresh lines of telegraph had to be constructed, more office accommodation had to be provided, the employees of separate companies had to be welded together and organised anew, and an administrative staff had to be trained. The Society in a judicious manner kept the subject alive, and when the time for action came it acted promptly and in such wise as to secure the friendly appreciation of the Post Office; so much so that the two may be said to have been in co-operation. It is remarkable how on this occasion again the minds of your Council were working in the same direction as the minds of the Post Office authorities. Although not seeking to dictate to the department, and prepared to learn that other plans might have something to recommend them, your Council made a suggestion only to find that it was in entire harmony with the views of the Post Office. What took place was this: A petition was carefully drawn up and transmitted to the Postmaster-General at the beginning of July, 1880. It was in the following terms:—

To The Right Honourable Henry Fawcett, M.P., Her Majesty's Postmaster-General.

The Memorial of the Council of the Society for the Encouragement of Arts, Manufactures, and Commerce

Respectfully Sheweth,—

That the Council are strongly of opinion that the time has now arrived when the charge on inland telegrams might be reduced, and a minimum charge of sixpence substituted for the present one of a shilling.

They submit that the charges on inland telegrams in this country are higher than in other European countries, the rates in France, Germany, Belgium, and Switzerland, all being lower than in England. It is even a curious anomaly that a telegram can be sent from any part of the United Kingdom to Belgium or to France for less than the smallest sum for which a telegram may be sent from one part of London to another.

The Council do not propose to make any suggestions as to the details of the method by which the reduction of charge should be effected; whether by employing a lower tariff within certain limited districts, such as the Metropolis and its suburbs, or the country within a certain radius of a provincial town; or, secondly, by adopting a word-tariff, with a minimum charge of 6*d*. The precise details are, the Council feel, safely to be left to the department itself.

They feel sure, however, that a reduction in the tariff would be accepted as a boon by a large number of those who are prevented, by the present rates, from using the telegraph as largely as they would wish, and that the business of the department would soon be so increased as to fully compensate for the lessened revenue which might be the first consequence of the proposed change.

(Signed)

Alfred S. Churchill, Chairman of the Council.

H. T. Wood, Secretary.

On the 17th of the same month a deputation from the Council attended at the General Post Office to support the petition. Lord Alfred Churchill, late Chairman of Council, introduced the deputation, and was followed by Mr. Chadwick. The Postmaster-General, Mr. Fawcett, was accompanied by several of the principal officials of the Post Office, including the Assistant Secretary for Telegraphs, Mr. Charles Patey, whose services, alas! were so soon to be lost to the State through his early death. After listening to the able arguments of Mr. Chadwick, Mr. Fawcett made a long, closely-reasoned and sympathetic reply. He declared emphatically for the second plan mentioned in the petition—viz., a word-tariff with a minimum charge of 6*d*.; he scouted the suggestion which had reached him that there should be two classes of telegrams, immediate and deferred; he showed how little would be saved for the Exchequer by limiting the reduced charge to certain towns and districts; and he expressed a firm opinion in favour of a uniform charge throughout the United Kingdom. While warning the deputation that the question was one the settlement of which must depend on the Chancellor of the Exchequer, he frankly placed before them estimates showing at what a moderate cost the change could be carried out, and left no doubt in their minds that he himself and the officials of the Post Office were on their side. But, as you know, a long delay was to intervene between promise and fulfilment, and obstacle after obstacle had to be surmounted; Mr. Fawcett did not live to send a sixpenny

telegram; a private member had to carry a resolution against the Government of the day before any practical step was taken; and it was not until October 1st, 1885, that the long-desired change was brought about.

In this inadequate review I have endeavoured to show you what has been the conduct of your Society in relation to telegraphs down to comparatively recent times. You have seen it encouraging a new invention, giving facilities for the demonstration of its importance and usefulness, recording and publishing its every advance, and helping Parliament and successive Governments to arrive at just conclusions with regard to it. You have seen your Society taking a leading and enlightened part in procuring the transfer of the inland telegraphs to the State, in promoting the purchase and direct working of the cables to the Continent, and in bringing about the introduction on a sound plan of sixpenny telegrams. You have seen it successful because, above all things, it was disinterested. I see no limit to the influence which enlightened men may bring to bear on the public and on public authorities if they are not actuated by selfish motives. May unselfishness always remain the characteristic of this Society, and may success continue to attend its efforts on behalf of humanity.

After delivering the Address, the Chairman presented the Society's medals which were awarded for papers read during last Session.

At the Ordinary Meetings:—

To Mr. T. Thorne Baker, F.R.P.S., for his paper on "Telegraphing Pictures."

To Mr. H. Pearson, for his paper on "The Diamond Fields of Brazil."

To Count Hirokichi Mutsu, C.V.O., Imperial Japanese Government Commissioner, for his paper on "The Japan-British Exhibition, 1910."

To Mr. Omar Ramsden, for his paper on "Silversmiths' and Goldsmiths' Work."

To Mr. Charles John Stewart (Public Trustee), for his paper on "The Public Trustee and his Work."

To Sir William Crawford, J.P., for his paper on "Irish Linen and Some Features of its Production."

To Mr. Sydney Perks, F.R.I.B.A., F.S.A., for his paper on "The Restoration and Discoveries at the Guildhall, London."

In the Indian Section:—

To Sir James Wilson, K.C.S.I., for his paper on "The Punjab."

To Mr. Saint-Hill Eardley-Wilmot, C.I.E., for his paper on "Indian State Forestry."

To Mr. J. Claude White, C.I.E., for his paper on "The Arts and Crafts of Tibet and the Eastern Himalayas."

In the Colonial Section:—

To the Hon. John McCall, M.D., Agent-General for Tasmania, for his paper on "Fruit Production in the British Empire."

Sir William H. White, K.C.B., in proposing a hearty vote of thanks to the Chairman for his Address, said that Sir John had in considerable detail and in a most interesting manner, traced the work the Society had done in furthering the introduction of telegraphic communication. The Chairman had quoted largely from the Proceedings of the Society, but he (Sir William White) did not think anyone could have produced the Address except Sir John, because he had knowledge, not merely of the Proceedings of the Society, but inside knowledge of the department where he played so important a part for so long a time; otherwise he could not have produced such a very interesting and complete history of events. He was sure all present would agree that they would have been delighted if Sir John had felt himself free to enter into controversial matters. He came very near doing so on one or two occasions, but he was so marvellously discreet that he always escaped over the thinnest ice, and came back to the firm ground of the Society. He (Sir William) assured the Chairman that all the members were deeply indebted to him for the labour he must have bestowed on the preparation of the Address, which would be a record to which reference would be made in the future as the authentic and authoritative statement of what had happened in the great improvement in public communications to which the Address referred. He thought the members would also agree that Sir John had sketched in a very clear and comprehensive manner the justification for the continued existence of the Society. He had, however, not drawn attention to one of its many advantages, of which the Chairman, Sir Steuart Bayley, and himself were illustrations—viz., that it was a refuge for destitute and retired public servants. When retired public servants ceased to be the victims of official control they came to the Royal Society of Arts, and sometimes became controversial.

Sir Steuart Colvin Bayley, K.C.S.I., in seconding the motion, said the Society greatly appreciated the honour of having a distinguished public servant like Sir John to succeed the late chairman, Sir William White. The Paper on Lifeboats which the Chairman gave to the Society a few months ago introduced the members to his admirable capacity for informing them on subjects in which they might not only take an interest but to which they gave serious assistance

The praise which Sir William White had bestowed upon the Chairman's discretion would be echoed by all present, but he was sure they would sometimes be very glad to dispense with it.

The resolution of thanks was then put, and carried with acclamation.

The CHAIRMAN, in reply, thanked the mover and seconder for the very kind words they had used, and the audience for the extremely cordial manner in which it had received them.

THE TRADE OF INDIA FOR 1909-10.

The Review of the Trade of India for the official year ending March 31st last has just reached England. It is written by Mr. C. W. E. Cotton, I.C.S., Officiating Director-General of Commercial Intelligence, and marks in almost every respect an appreciable advance upon the statistics for the preceding twelvemonth, which had revealed a deplorable weakness in almost every direction. The import market had been glutted, food grains had attained high prices, and there had been a general feeling of insecurity created by the slow recovery of credit in Europe and America, the consequence being that such small improvement as was manifested was scarcely perceptible in any of the trade returns. The figures for 1909-10 have thus proved the year to be one of recuperation rather than development, and, although all unhealthy symptoms have not yet disappeared, Mr. Cotton considers that "India, after an unusually prolonged period of trade sickness, may be regarded as almost convalescent."

There was a marked improvement in foreign trade at the beginning of the year under review. During the calendar year 1909 there had been considerable advances in the total value of imports into the United Kingdom, France, Germany, Belgium and the United States, and in all except the last the sum of the exports is considerably higher. The Indian monsoon rains in 1909 were exceptionally favourable, and the increase in total estimated out-turn exceeded 14 per cent. in the case of jute, 22 per cent. in the case of cotton, 26 per cent. in that of wheat, 43 per cent. in rice, and 24 and 44 per cent. in the two chief descriptions of oil seeds.

Regarded as a whole the export trade was unusually active, particularly in the last four months of the year, and the high prices of wheat, cotton and oil seeds not only directly benefited the cultivators in almost every province, but served to replenish automatically the stocks of gold in the country which had been diminished by abnormal imports and the American banking crisis. In the matter of imports, too, the record is also somewhat unsatisfactory, as in all those lines which are regarded as indices of returning industrial activity the recovery has been only partial and incomplete. The value of metals and manufactures, and all kinds of machinery, has again fallen, the railway indents were smaller, and the increasing imports of sugar from the Dutch Indies, in spite of the rise in prices, are hardly matters for congratulation, when it is considered that the acreage under cane in India largely exceeds that of any other country in the world.

As for the future, Mr. Cotton considers that further trade improvement is probable during the next twelve months in Europe and America, but that for India the restoration of industrial activity and the development of those internal exchanges which have been so conspicuously in defect during the last three years, can only be assured by a continuance of general agricultural prosperity.

Without attempting to review the detailed heads, which would occupy far too much space, one may notice here some of the more characteristic features in the year's imports. In regard to sugar, the twelvemonth was marked by a steady rise in prices due to a general shortage of the beet crop as a result of bad weather on the Continent, which increased production in Cuba, the West Indies and Java was not expected to make good. Ten years ago, before the Brussels Convention and the abolition of the bounty system, the production of beet sugar was about double that of cane, but in 1909 it is calculated that the cane crops of the world amounted to about eight million tons, excluding India, as compared with about six million tons of beet. The combined total is below the world's estimated annual consumption of 14½ million tons, and thus proved insufficient. The imports into India of sugar of both kinds rose by about 4·4 per cent. in quantity, and 5½ per cent. in value. The chief sources of supply of cane sugar continue to be Java and Mauritius, while in beet sugar Austria-Hungary continues to retain the dominant place. In regard to India's own potentialities as a sugar producer these are hampered by a variety of circumstances, including the difficulty of concentrating cultivation round central factories and the fact of the demand being practically restricted to molasses and low-grade sugar, produced by wasteful and primitive methods.

In the imports of mineral oil there was a noticeable decline. Mr. Cotton remarks that the discovery of oil at Maikop (in the Caucasus), the successful proving of the Red Sea oil-field and the conflict of interests in Mexico between the Pearson and Waters Pierce groups, temporarily made the industry a speculative medium on the London Stock Exchange only less active than rubber, and this activity found a parallel in Burma, where during the last two years no fewer than seven new companies have been floated.

The imports of coal, which represented 17·2 per cent. of the value of raw materials imported into India twelve months ago, fell to 15·1 per cent., this being due apparently to restricted industrial activity in several branches of trade.

Cotton goods maintain their position of preponderance among imports of manufactured

articles, and on the average of the past three years constitute about 34 per cent. of the total values of all imports. In the year under review, however, cotton in the Western markets continued in a state of great depression, spinners and manufacturers alike being affected by discouraging and irregular demand and an extraordinarily narrow margin between the prices of the raw material and those of the finished products. In yarn there was a decline in the year's figures, but cotton fabrics rose in value, and of these the proportions supplied by Great Britain were as follows:—grey goods 99 per cent., whites 98 per cent., and coloured goods 93½ per cent. of the total. The prices of silk goods imported fell, owing partly to the large out-turn of raw silk in China and partly to a falling off in the American demand, and in spite of the shortage in Continental supplies caused by the destruction of the silk filatures in the Messina earthquake. Business in French and Italian silk fabrics was dull throughout the year and this reacted on the Indian trade. In the imports of woollen manufactures into India there was a considerable setback due to trade depression and the legacy of large stocks which heavy speculative purchasers of the previous two years had bequeathed.

The most interesting features of the list of Indian exports, which show advances in most cases, are the high percentages of increases under wheat and wheat flour, pulses and millets, seeds, cotton raw and wool raw, while the only noticeable decreases are under jute raw, indigo and coffee.

As regards rice, there was an unusually good crop in Burma and the two Bengals, some shortage in southern India, a further advance in foreign exports and a slightly lower range of prices. The lower prices for jute encouraged increased acreage under rice in the two Bengals. Ceylon continues the largest single purchaser of Indian rice, the exports to the Straits Settlements rose considerably, while of the western countries Germany is the most important consumer. The United Kingdom and Austria-Hungary also took larger shares.

The Indian tea trade continues its career of prosperity, and prices were maintained at an unusually steady level, the average price of tea sold at Calcutta auctions marking an advance of 13 per cent. over last year's figures. The proportion of the trade which goes to Russia is of growing interest and importance. The demand in this case includes all grades, and the bulk of the shipments go *via* Colombo and Vladivostock and thence by Trans-Siberian Railway. The exports to Australia during the last two years have decreased, but those for Canada and the United States show a satisfactory increase in spite of the disorganisation of the trade caused by rumours of a proposed import tax on tea entering the United States. The exports of metals and manufactures thereof still occupy a very modest position, representing less than 1 per cent. of the total imports. Manganese ore is the only item of importance, the value having increased from £388,400 to £738,000 in the past five years. Under the small but interesting head of Chinchona bark, we note that the exports have not yet made good the decline recorded in 1908-9, but in spite of the competition of Java bark, which is said to yield a higher percentage of sulphate, the specific value has advanced. It mostly goes from Madras to the United Kingdom.

The export trade in coal continues exceedingly unenterprising, and even the dislocation caused by the prolonged strike in Australia was not taken full advantage of, the quality of some of the coal shipped being so bad as seriously to prejudice further demand. The production of Indian coal in 1909 is estimated at 11,870,114 tons, as against 12,769,635 tons in 1908. A railway test made during the year under review with shipments of first-class Bengal coal, of Natal coal, and of Australian coal, gave the following result:—Bengal coal ran 26 lbs. per train mile; Natal, 27 lbs. per train mile; and Australian, 30 lbs. per train mile.

On the average of three years ending 1908-9 raw cotton represented 30 per cent. of the total value of raw materials exported from India. In 1909-10 the proportion rose to the extraordinary figure of 37½ per cent. In fact, raw cotton supplanted raw jute as the most important single article of exportation.

The world's wool trade has recovered more quickly than the cotton trade from the results of the American panic in 1907. The cost of both raw material and manufacture has risen, as the result of increased consumption on the Continent and a particularly strong American demand.

Under the head of "Articles manufactured and partly manufactured," jute products continue to fill a very prominent place in the export of Indian manufactures. In the year under review their percentage of this rose from 43 to 44·9 per cent. in value, though there was a heavy fall alike in the price of the raw material and the mill products. Cotton manufactures represented 31·3 per cent. of the total value of Indian manufactures exported and 6·5 per cent. of the whole export trade.

The trade of India according to countries reveals some interesting features. The United Kingdom of course heads the list, and the total value of her trade rose in value from 75 to 81 million pounds sterling, but her aggregate share in the total trade fell from 41·1 to 40·2 per cent., this being due to a considerable increase of Indian exports to foreign countries, notably to Java and the United States. The order in which the principal foreign countries rank is thus:—Germany, China, United States, Japan, Belgium, France, Java and Austria-Hungary. Germany, the first of these, owns 7·2 per cent. of the total trade and the new system of registration which notes the ultimate instead of the immediate destination of exports, will further confirm this predominance.

Lastly, it may be noted that while the net imports of silver fell off very considerably, the imports of gold exceeded 16¾ million pounds sterling, the highest total ever recorded. This is no doubt in a sense a measure of the general revival of trade, which is further reflected in an increase of 7·7 per cent. in the aggregate tonnage entering and clearing at Indian ports over the figures for 1908-09.

HOTEL SCHOOLS ON THE CONTINENT.

The business of conducting a first-class hotel has developed into such an international character, and requires such wide scope of training and knowledge, that on the Continent steps are being taken for the establishment of schools to furnish this special training. In Switzerland such a school has been in operation for years. The prevailing method of training young men for this business in Switzerland is to send them to the large hotels in foreign countries, where foreign languages and customs may be learnt first hand, and experience is gained that enables the young man to engage in business and put into practice the ideas he has gleaned in different parts of the world. In Austria there is a Government institution at Innsbruck, in connection with which there was established, a few years ago, a course of lectures and general instruction in hotel management, which has proved very successful. Instruction is given by competent professors under the direction of a board appointed by the Minister of the Interior. The course is known as the "Gästegewerblicher Fachkurs." Here, for a few weeks in the year, special information and technical knowledge relating to the hotel business are taught. The eastern part of Austria, like Switzerland, offers great attractions for tourists, and is visited each year by thousands. One of the secrets of their great success is the fact that hotel managers in these places in Austria have travelled widely, thus acquiring several languages, and have familiarized themselves with the tastes peculiar to each nationality. In Switzerland the Schweizer Hotel Verein has opened an hotel school under the name of the "Fachliche Fortbildungsschule des Schweizer Hotel Vereins," at Cou, near Lausanne, in a beautiful park overlooking Lake Geneva. Here the students receive careful attention as regards their physical, mental, and moral development. The institution is thoroughly organized and discipline is strict. The cost of board, lodging, and tuition is, for a native Swiss, £4 16s. per month; for a foreigner, £6 per month. Special reduced rates are quoted to native Swiss who are in straitened circumstances, but not more than four are admitted under these circumstances in any school year. According to the American Consular Assistant in Paris, the French hotel-keepers have conceived the plan of establishing a hotel school in Paris. One of the chief objects is to bring some system into the training of an hotel clerk. On account of the complex organisation of the modern hotel, with its electric and ice plants, laundries, hot-water supply, and various other departments, the manager with only a slight knowledge of book-keeping, hotel service, or the kitchen, is no longer able to fill his place adequately. A knowledge of hygiene, engineering, architecture, and especially languages, is essential. The Syndicat Général de l'Industrie Hôtelière et des Grands Hôtels de Paris, in January, 1910, organised a school, to be known as "l'École de l'Industrie Hôtelière," and an institution for lodging the students. The students will at all times be in constant touch with the director of the school, who will be a representative of the Syndicate. The number of boarding students for the first year has been limited to thirty. The minimum age of admission is sixteen. At the end of the school year, upon successfully passing the prescribed examination, certificates will be granted to all students meriting them, and the Syndicate thereupon will place the student for further instruction in one of the large hotels belonging to the union. The course of study during the first term is as follows:—Study of foreign languages, English and German; shorthand and typewriting, mathematics and book-keeping, geography and history, civil and commercial law. These branches are taught entirely from the standpoint of the hotel-keeper, and in consideration of the service to the guests. The course of study during the second term is as follows:—Political economy, hygiene, electricity, heating, insurance, laundries, menus, kitchens, etc. The afternoons will be devoted to visiting industrial establishments that supply hotels.

THE LIBERIAN SUGAR INDUSTRY.

In the early history of the Liberian Republic a large quantity of sugar was manufactured, and during the civil war large quantities of brown sugar were shipped to the United States. Along the banks of Liberian rivers are thousands of acres of land that could be profitably utilized for the culture of sugar-cane. In the case of forest land, the undergrowth is cut in January and the large trees felled about the beginning of February. After two or three weeks the dried vegetation is pulled up and the débris burned off. The land is dug up with hoes in rows about six feet apart. In three months after planting the cane attains a height of three or four feet. In nine or ten months the cane is ready for cutting, which is done with cutlasses, and the tops with three or four joints are preserved for replanting. According to the United States Chargé d'Affaires at Monrovia, cane-culture in Liberia is undeveloped. There is great need for capital to provide suitable machinery for preparing the soil, and for the introduction of modern methods of culture. The cane is ground in an ordinary three-roller mill, with a trough under it to catch the expressed juice which is carried to a reservoir, whence it is taken as required for cooking in large kettles. In

cooking, unslaked lime instead of cream of lime is used to produce granulation. When the juice attains a ropy thickness, a little is dropped into a bowl of water to determine if it has been sufficiently cooked. When it settles in the bottom of the bowl like candy it is ready for the next process, called in Liberia "striking," that is, it is removed from the kettles by means of long-handled dippers to a vat where it is stirred with a wooden ladle until it cools. It is then placed in wooden barrels with holes bored in the bottoms, sharpened sticks being run through the sugar to the holes to guide the dripping of the molasses. The barrels are placed on two poles over vats which catch the molasses as they drip. When the sugar is free of molasses it is dry and of a light golden colour. In this condition it is sold locally for about threepence a pound. Notwithstanding the large quantities of excellent cane grown in Liberia, and the much larger quantities that could be produced, almost the entire sugar consumption of the country is of imported beet sugar. This is largely due to the lack of capital to enable the sugar-planters of Liberia to compete with the beet-sugar producing countries.

PARAGUAYAN RUBBER.

In 1909 the first attempt was made to produce rubber in Paraguay. The experiment was tried by an industrial company owning extensive tracts of land which it exploits for the production of timber and yerba maté (Paraguay tea). On the lands of this company, in the northern part of the Republic, is a tree known in the local Guarany tongue as the "mangaicy" tree. In the Brazilian State of Matto Grosso, lying just north of Paraguay, the same tree is known as the "mangabeira." It is also called the "mangava." One authority states that all of these names refer to the rubber product of the tree, and that its true name is "curupicai," or "curupicahy." Possibly some assistance in identifying the tree may be gained from the following extract from a work on Paraguay by a German consul in that country:—"There are in Paraguay only a few species of gum woods growing in a wild state; among others should be mentioned the 'manga-ysy' and the 'ybyra camby.' Efforts are now being made to cultivate india-rubber trees, and a Brazilian species has been chosen called 'Manicoba' which grows more quickly and winters more easily." A description of the mangaicy tree upon which reliance could be placed for a proper classification has not been obtained. It grows in a distant part of the country, and accounts of it are as variable as the names applied to it. The mangaicy yields a milky sap known in Matto Grosso as "chiringa," which is collected by making a series of V-shaped incisions, one above another, in the bark of the tree. The lower points of the incisions are connected by cuttings, and a cup for catching the milk is fitted closely to the trunk of the tree beneath the lowest incision. After the milk is gathered it is coagulated by a solution of alum. The liquid matter is then drained off and the curd-like substance remaining is dried and subjected to a pressure which forms it into the rubber exported from Paraguay. In Matto Grosso the rubber product is known as "borracha." The trees are tapped from October to April, each tree yielding from eight to ten pounds of milk. A tree can be tapped every other year if conditions for growth are favourable, otherwise it should not be tapped more often than every three years. It is stated by some that a tree can be tapped in about three years after planting. According to others, they are not mature enough until six or seven years' old.

TRADE IN SOUTHERN PERSIA.

The condition of commercial affairs in Southern Persia during the year 1908-9 appears to have been very depressed, judging from the recent consular reports on Bushire, Bunder Abbas and Lingah. The most prominent feature in the case is the weakness and inability of the local governments of Shiraz and other chief towns to maintain order, and want of support accorded until quite recently by the policy of the British Government, within whose sphere of influence the region has been included under the Anglo-Russian Agreement. On the caravan route from Bushire to Shiraz, tribal fighting has been chronic, and on the road from Shiraz to Isfahan constant robberies and looting have continued to paralyse all commercial activity. The piece-goods trade suffered more especially, and Manchester lost at least £120,000 worth of business on the previous year's figures. Importing companies themselves have frequently had goods ordered out and thrown on their hands by bankrupt buyers, and the amount of outstanding claims presented for recovery from defaulting Persian traders during a period of eighteen months from the beginning of 1908 totalled more than £20,000.

The lack of transport on the great caravan route to Shiraz was also a factor which increased the difficulties of merchants. Extortion on the part of the armed tribesmen infesting the route to Shiraz, and frequent robberies, have made the lot of the muleteers hard; many indeed have left this route with their animals in order to find a more peaceable living on the northern caravan routes, where, it is presumed, Russian influence ensures greater security. The exactions, robberies, and diminished transport along the routes where British goods are so largely borne, have not only diminished the British trade, but have encouraged their place being taken by foreign merchandise imported from the north. Not only has British trade thus suffered very severely from the disorganized condition of government in the south, but unfortunately the prospects of an early return to the quietness necessary for the recovery of trade are not hopeful. The import figures of 1909-10 so far point to a more startling decline in imports than even those of the year under review.

At Bunder Abbas also trade has been bad, owing chiefly to the disturbed state of the country, which has rendered the trade routes most insecure. The total commerce of the port has declined by over £104,000 as compared with the previous year, a decrease of nearly 19 per cent. The imports from the United Kingdom have declined 5 per cent., and those from India 40 per cent., while the decreases in exports to those countries are similarly 35 and 13 per cent. The Consul adds that an increase of trade is not likely to occur until order has been generally restored in Persia, and that even then improved communications will be necessary to admit of any considerable expansion.

SOUTH AFRICAN PROGRESS.

According to the American Consul-General at Cape Town, one of the most striking indications of the healthy and prosperous condition of the country is the increase in railway receipts, and still more the demand for rolling-stock and equipment, which has necessitated the immediate placing of orders amounting to £700,000. Besides the branch lines now under construction in the Transvaal, Natal and Cape Colony, and other extensions in all these Colonies sanctioned by Parliament, the Cape to Cairo Railway probably will be completed by August, 1911, as far north as the Star of the Congo Mine, across the Belgian frontier, to tap the rich copper deposits in the Tanganyka district. In the Transvaal there are building contracts in hand to the extent of between £2,000,000 and £3,000,000 for the erection of the various government buildings for the Union Government at Pretoria, besides museums, schools and colleges at the other cities in the Transvaal. In addition to these, there is to be a new tramway line at Pretoria, costing about £80,000, and the installation of a complete sewerage system costing £100,000.

BRITISH COLUMBIAN HORTICULTURE.

The growth of the fruit industry of British Columbia may be estimated by returns of imported nursery stock which the provincial inspector of fruit pests has recently transmitted to the Government. The number of trees and plants inspected at Vancouver during the first four months of 1910 was 2,719,000. Every tree and plant is inspected as it passes through the station. This entails a vast amount of labour. Owing to this rigid inspection before the stock is delivered to the buyers for planting in Okanogan, Similkameen, East and West Kootenai, and the boundary country, there is not a trace of the San José scab or the brown tail or gipsy moth. The equal freedom from the codling moth corroborates the statement that the nursery stock received for planting purposes is subject to most rigid inspection, as well as fruit brought from eastern Canada, United States, and other countries. The importance of this fact to fruit-growers can hardly be overestimated, as it enables them to guarantee the soundness of fruit to purchasers. At the present rate of orchard planting, a large proportion of the arable land of the province will be used for this purpose. The fruit grown, according to the United States Consul-General at Vancouver, is of the same general character as to size, colour and flavour, as that grown in the famous orchards of the States of Washington and Oregon. During the year 1909 there were brought into the city of Vancouver 113,163 boxes of apples, pears, peaches, apricots, quinces and plums, which, with the amount received from the orchards situated in the province —about 35,000 boxes—shows a large consumption of fruit in Vancouver and the surrounding districts. Apples have been grown successfully at an altitude of 4,500 feet near Rossland, and from this district large shipments are expected, which will come into direct competition with those of the fruit grown in the States of California, Oregon and Washington.

THE GRAPE INDUSTRY OF ALMERIA.

The table grapes known commercially as Malaga grapes, are exported from Malaga in very small quantities. Almeria—the principal city of the province of the same name, situated about one hundred miles east of Malaga—is the centre of the grape-exporting industry of southern Spain. Originally the Almeria or Malaga grapes were cultivated only in, and about, a small town called Loja about fifty miles north of Malaga. Cuttings were distributed throughout the entire district, but Spain's finest table grapes, and the only grapes that will retain their freshness, firmness, and flavour for months after being cut from the vine, are the product of the old cuttings taken from Loja, and now cultivated in the province of Almeria. Owners of vineyards in the Malaga district have made repeated efforts to produce a grape possessing the keeping qualities of the Almeria fruit, without obtaining satisfactory results. Cuttings taken from Almeria produce a different grape when transplanted outside of that particular district. Cultivated in and about Malaga, the Almeria cuttings produce a tender, thin-skinned grape, more or less of the order of the muscatel. As no artificial means are adopted to aid in preservation, the splendid keeping qualities of the Almeria grape must be due to some peculiar properties contained in the soil of that district, combined with extremely favourable atmospheric and climatic conditions, as the fruit is thick-skinned and capable of resisting decay for seven or eight months when properly packed. There are a great many varieties of soils in which the grapes are grown—lime, clay, gravel and slate; but, according to the American Consul at Malaga, opinions differ as to which is most favourable for grape producing, some maintaining that the gravel and slate soils are best owing to the fact that they are more easily penetrated by the roots of the vine. The further they get down,

the better soil-nourishment the root receives. As regards temperature in the northern or higher districts, the average is 60° F. maximum, 52° minimum. In the southern or seaboard districts the average is about 110° maximum and 66° minimum. In Almeria the thermometer rarely falls below freezing-point. Thus it follows that the grapes in the latter districts are ripe about the beginning of August, while in the northern section the cutting is done from about the middle of September to the end of October. Heavy rain after the fruit has reached the ripening stage is prejudicial to the keeping quality of the fruit, especially if the grapes are cut too soon after a rain. Much rain in the months of April or May is dreaded by the grape farmers, as it is during these months that they apply the pollen from the black or "castiza" grape to the white export or "Ohanes" grape. This is probably the most anxious time for the producers, as their crop depends on the success of this operation. The greater part of the packing is done at the vineyards where the grapes are cut. Frequently, however, the grapes are cut, placed with care in esparto baskets, and carried on the backs of mules and donkeys to warehouses at the port, where the bunches are carefully inspected and all unsound and small fruit cut off, after which packing in barrels takes place. Grapes are often brought in this manner from villages as far as twenty miles inland. Some grapes already packed come from a distance of over sixty miles to the port, from the borders of the province. Cleaning and packing are done by women. The cleaners remove with scissors all berries that may be in any way damaged or stained, taking great care at the same time not to pierce the good berries. It is at this stage that classification takes place; the cleaner, on laying down each bunch, judges from its appearance, colour, size of berry, etc., to which class it must go. All grapes are packed in ground or granulated cork, the barrel being filled with a layer of cork and grapes alternately, while the packer shakes the barrel on completing each layer in order that all interstices may be filled up. The packers re-examine each bunch as they fill the barrels, snipping off with scissors any doubtful berries that may have escaped the eye of the cleaner. The importance of the grape trade of Almeria is shown by the last year's exports, amounting to 1,576,936 barrels, and production is said to be steadily increasing.

JAPANESE AND COREAN GINSENG.

It is a common belief in China that when all remedies have failed, and death is near, ginseng can restore the breath of life and ensure longevity. Many people in high stations in the East confirm these medicinal properties, hence the persistent demand for the root, concerning whose price fabulous sums are reported to have been paid. Its value, however, depends upon shape, texture, and manner of curing. To be valuable, the root must be so as to resemble somewhat the human form and semi-transparent, dry and flinty. As it is sold by weight, the size is also of importance, a good specimen sometimes bringing as much as £10, though inferior shapes and sizes bring very much lower prices. Ginseng roots of grotesque shape are more highly prized than the symmetrically-formed product. According to the Canadian Trade Commissioner in China, almost the whole ginseng trade of China is controlled by a group of Chinese merchants, whose headquarters are in Hong-Kong. They fix the prices, both wholesale and retail, and regulate from year to year the amount of ginseng imported into the country. In this way a practical monopoly of the trade is obtained. This is the reason why it is so difficult for foreign growers of ginseng to deal directly with Chinese merchants, and it is this feature of the trade that makes it more profitable, as a rule, to the small grower in other countries to sell his ginseng to some local commission house rather than to ship it to China himself. Japan is the great source of production of the ginseng consumed in China, and it is cultivated principally in Aizu, Shinano, and Izumo. It is a perennial plant, growing usually three to four years, when it is harvested. The yellowish-white root measures five to six inches long. The soil once cultivated with ginseng must not bear the same crop for fifteen to twenty years, otherwise it is liable to be attacked by plant diseases and pests, especially in an unfavourable season. The cultivation of ginseng in the Izumo district is carried on with greater attention and care than are bestowed upon it in other parts of Japan. Ginseng prefers a rather cold climate, and thrives well on a slope declined northward and thoroughly drained, and on clay or even sandy soil, provided the climatic conditions are favourable for its growth. In September the fourth-year plant is harvested, and the roots are carefully dug out, so as not to injure the rootlets, packed in bags and sold directly to the steeping factories or intermediate merchants. The harvested roots are washed clean and sorted into classes, according to their size. They are then put into lukewarm water in a kettle, and the temperature raised to nearly boiling-point, when the steeping or cooking will be finished. The steeped roots are then taken out of the kettle and spread out thinly. Any moisture on their surfaces is dried off as quickly as possible by fanning. If a properly-steeped root is cut through with a knife, the white translucent part in the middle of the root should be quite round and not irregular in shape. The roots are then transferred to an oven and dried by charcoal heat, from four to eight days according to the size of the roots. The oven consists of two boxes, upper and lower, the bottom of which is of thick pasted paper, and inserted into the oven. A charcoal fire is kept just under the two boxes, so that the drying temperature can be regulated in the oven itself after practical experience. In the beginning of the drying operation, only the lower box is

filled with the roots, the upper one being left empty, and the temperature of the lower box ranging about 150° F. At the expiration of ten hours, when the roots become soft and small wrinkles appear on their surface, the temperature is lowered to about 130° by covering the charcoal fire with straw ashes. After another ten hours, when the bulk of the roots becomes much smaller, the contents of each of the lower boxes are collected into one and transferred into the upper box, where the roots are gradually dried up ready for sale. The lower boxes thus emptied are filled with fresh roots, the same process as before being repeated. Nearly the whole quantity of ginseng produced in Japan is exported to China through the ports of Yokohama and Kobe. In Corea the ginseng industry has become a government monopoly. The industry is governed by strict regulations, and is carried on by farmers specially licensed, who cannot discontinue the business without special permission, and who must carry it on in districts specified by the government. The authorities inspect the product, and from it choose the finest roots for the making of red ginseng, paying a fixed and uniform rate therefor. The famous red ginseng, which is such a favourite in China, is made by steam-baking the yellow or white ginseng. This red ginseng is cured only at Songdo, its manufacture and export being a government monopoly.

EMPIRE NOTES.

The Parliament of United South Africa.—The opening of the first Parliament of United South Africa by H.R.H. The Duke of Connaught, was important, not only from the point of view of the results which are likely to follow in that country from the establishment of a responsible Government—the sphere of whose duties will cover the whole of that great Dominion—but from the influence of this step on the Empire itself. The fact that Australia, New Zealand and Canada sent distinguished representatives to meet the Royal Duke and to express the good wishes of the countries they represented on the consummation of the great movement which has been so fittingly marked by the proceedings at the opening of the new Parliament, is indicative of the spirit of union between the various parts of the Empire. How far the principle of federation which has been adopted in South Africa is an improvement on the Commonwealth principle of Australia, is a question which can only be determined by a consideration of local conditions. At the same time, it is interesting to note that the Federal Government of Australia appears to be moving more and more in the direction of federation, and of limiting, as far as possible, the powers of the separate States' Parliaments.

The South African Industrial Commission.—At a Commercial Congress, held in Bloemfontein in July last, the Hon. F. R. Moor, the present Minister of Commerce and Industry for the Union of South Africa, expressed his willingness to promote, as far as possible, a Commission of Inquiry into the agricultural, commercial and industrial conditions and needs of South Africa. The proposed inquiry will cover a wide field, including the conditions of existing industries, the cost and class of labour employed, the production of raw materials, the effect of the present tariff and railway rates, the prospect of developing fresh industries, and the increased use of white labour. The question also of facilitating the export trade of the country will be considered, and the improvement of transport arrangements, both by land and sea. The Commission will consist of two members each from Cape Colony and the Transvaal, and one each from the Orange River Colony and Natal.

Westralia's New Gold Mine.—There seems to be every prospect, from the recent mining developments in the neighbourhood of Southern Cross in Western Australia, that a new Kalgoorlie has been discovered. The Bullfinch Mine, 22½ miles from Southern Cross—the first of the series of mines being opened on the line of reef running to the north-west of that old mining centre—is yielding remarkable results. These, however, are not of the "patchy" character of some of the early gold finds of Western Australia, which occasioned so much excitement when discovered, and became so disappointing afterwards; the nature of the ore bodies indicates permanence. The outcrop of the mine, the examination of which led to the discovery of the auriferous character of the district, is a dense ironstone, similar, it is said, to thousands seen all over the country, and to all appearance equally barren. This outcrop, which was only a foot or two in height, was scarcely noticeable from a short distance. No visible gold appeared in it, but, when samples were assayed, they were found to contain seven ounces of gold to the ton. This assay was confirmed by bulk samples as the mine was opened. The lode appears to strike north-west and south-east, and has a very steep underlay to the south, which, like the Boulder lodes, is practically vertical. It consists of schists, ironstone and quartz, and the vertical shaft on the west shows it is in greenstone, which, according to geologists, and also to the experience of the Boulder, Gwalia and Great Fingall Mines, is the best indication of permanence in Western Australia. Other mines have been opened on the line of the Bullfinch reef, some of which consist of immense ore bodies carrying payable gold. An area of 10,000 acres has been leased to various mining parties in the vicinity already. Recently, some members of the Ministry, accompanied by the Government geologist, visited the district, and their report fully confirms the magnitude and importance of the discovery, which will have far-reaching effects on the State, and will materially assist the movement towards

immigration that has been so vigorously taken up by the Government during the last few months.

The Northern Territory of Australia.—After many months of debate, the Northern Territory Acceptance Bill has now passed through all its stages in both Federal Houses of Parliament, and the Commonwealth becomes possessed of a large tract of country. By agreement with the South Australian Parliament, the Federal Government assumes certain obligations relative to railways and development, and takes over a debt of about £3,000,000, accumulated on behalf of the Territory. Although for some time to come it will prove a source of loss to the Commonwealth, it is anticipated that in a few years it will become a flourishing state and provide homes for many hundreds of thousands of settlers. For purposes of defence it has become a matter of necessity that it should be annexed by the Commonwealth, and for that reason no time should be lost in settling a large number of people upon it. The population of this immense area, comprising as it does 523,620 square miles, according to the latest return, is only 3,004, of which number 1,081 are Europeans, and the remainder Asiatics. There is no possibility of stating the number of aboriginals, but they are numerous on the coast-line. The territory is rich in mineral wealth, and during the year 1909 gold bullion amounting to 7,164 ozs. and valued at £23,526 was exported. Tin ore and concentrates to the extent of 454 tons, valued at £37,496 were also exported. A small quantity of copper, 118 tons, was raised, and 73 tons left the country. The export of wolfram amounted to 44 tons, valued at £4,294. Recent exploration has shown that there is some magnificent country in the northern and central portions, admirably suited for raising sheep, horses and cattle, and when the south to north transcontinental railway is constructed this belt of country will be of immense value.

An All-British Cable.—The trans-Atlantic cable systems represent the one missing link in an all-British cable communication, and the case to be brought forward shortly for an "all-red" cable route is a strong one, alike with regard to political, social and commercial imperial interest. There are at present sixteen cables across the Atlantic, controlled by four different companies, and now the United States' grip of the entire system threatens to create a situation which cannot be contemplated without serious uneasiness, as the control of these companies is gradually passing into the hands of a great American trust. With the United States monopoly the demand for a cable controlled by the British Government will have behind it a practical force hither unappreciated by those who have treated the scheme as a mere vision of the empire builder.

Canadian Markets for New Zealand Meat.—There is evidently an excellent opening for the New Zealand frozen lamb and mutton trade in Canada, according to a statement by Mr. W. A. Beddoe in the course of an address before the Auckland (New Zealand) Chamber of Commerce recently. He said that it had occurred to him that the frozen mutton trade which might be developed with Canada was somewhat neglected. As Canada had very few sheep—there were only 3,000,000 to a population of 8,000,000 people—there ought to be a good market there for New Zealand mutton. In Vancouver they would be only too glad to get New Zealand frozen mutton, and in Montreal there were no fewer than 600,000 mutton-eating people. There was a trade there in embryo. They recognised in Canada that if they were to do a big trade they must buy as well as sell. Although Canada was a great butter and cheese-producing country, this only applied to the east. Western Canada was not supplied as it might be, for the simple reason that the distance from Halifax to Vancouver was greater than from Halifax to Liverpool. He thought that in Western Canada, a fruit-growing and mineral-producing country, there was a big market for New Zealand dairy produce, and that at Montreal there was a big market for New Zealand frozen meat.

A Valuable Indian Sugar by-Product.—In India, bagasse—the refuse from the sugar cane—has up to the present, only been used for fuel. This is evidently an unnecessary waste, as in the West Indies this refuse is turned into paper-pulp and is used by local paper manufacturers and also exported, realising from £5 to £15 per ton, according to quality. In Cuba, too, practical tests are being made in this direction, and were described in the *Journal* of the 4th inst. It appears, moreover, that the quality of the pulp can be greatly improved by the addition of fibrous materials, such as bamboo and grasses, banana stalks and leaves, of which there is a plentiful supply in India. As it is estimated that there is a ton of refuse to each ton of sugar produced, and as the sugar of India yielded over two million tons last year, at the lowest computation, the bagasse should bring in ten million pounds sterling per annum. Nowadays, manufacturers realise that in many trades the profits can only be culled from by-products.

GENERAL NOTES.

THE SWISS DAIRYING INDUSTRY.—Dairy farming constitutes an important industry in Switzerland. The production and treatment of large quantities of milk, consumed in numerous chocolate factories and milk-condensing concerns in the Confederation, the domestic consumption of milk, butter and cheese, and the preparation of cheese for export, engage the attention and services of a large number of people. There are 2,100 dairies in Switzerland, which employ on an average four persons each, making a total of 8,400 people

engaged in the business. Of these about 1,400 are devoted to the production of Ementhal cheese, a brand which constitutes the principal part of the cheese exports. This calculation does not include a considerable number of people who are engaged in what are called "Alps," a term applied to the little valleys in the higher mountain altitudes, where peasants take their cows in summer, and where in small huts and stables the attendants and animals remain for several months in the year. The cows thrive on the sweet tender grasses that grow in these high altitudes, and there, by crude methods, the herdsmen convert the milk into cheese and butter. Many of the men who attend the animals in the Alps do not leave these mountain retreats during the entire season, enduring a life of isolation and toil, which is, however, spent in the midst of the most magnificent scenery. The value of Swiss cheese exports for 1909 was £2,433,000, and the price was higher than in 1908. Notwithstanding the increase in the volume of the exports and the advance in price, the Swiss manufacturers complain of small profits on the year's business, claiming that it is because of the superior quality only of their products that they are able to compete in the foreign markets.

GLASS AND PORCELAIN BRICKS.—The demand for glass and porcelain bricks is very keen in Germany, and many factories in that country are now producing them. Three types of glass bricks are well known. One, the Falconnier hollow brick, of singular and irregular shape; another, a hollow, rectangular brick, similar in shape to a common brick; and finally, a pressed glass brick made in the form of a thick letter U. Glass bricks, when carefully handled, seldom crack or break, but they are very sensitive to changes of temperature. Porcelain bricks are exceedingly uncommon, although there are a few houses in Hamburg the exterior walls of which are faced with them. These bricks were made near Stettin, from clay found on the island of Bornholm, in the Baltic. It seems unlikely that they will ever become popular, as they are very heavy and expensive, and in the case of glass bricks the chief obstacle to their more extensive use is their inability to support more than their own weight, or even this when the wall exceeds fifteen feet in height. Consequently girders must be provided, or ordinary window openings made in such a manner that the walls of glass sustain no pressure. The bricks are delivered to contractors loosely packed in straw. The mortar used in laying them is composed of one part of fine sand to four parts of cement. The hollow, rectangular glass bricks have become of late the most popular form among German builders. They are thicker than the Falconnier bricks, and are more valuable for fire-proofing purposes. Glass bricks can never be more than special-purpose building materials, particularly useful where walls instead of windows are essential, while at the same time light must be provided.

THE BOTANICAL JOURNAL.—The *Quarterly Record* of the Royal Botanic Society has been discontinued, and its place is taken by the *Botanical Journal*, a monthly periodical. The first (October) number contains an editorial article on the work of the Society, reports of the proceedings, general articles and notes, and is illustrated with three excellent coloured plates.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 21...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. C. R. Darling, "Industrial Pyrometry." (Lecture I.)

Bibliographical, 20, Hanover-square, W., 5 p.m. Sir Herbert George Fordham, "Descriptive Catalogues of Maps: their Arrangement, and the Details they should Contain," with an Exhibition of Specimens.

Geographical, Burlington-gardens, W., 8.30 p.m. Dr. Filippo De Filippi, "Some Results of the Duke of the Abruzzi's Karakoram Expedition."

Junior Engineers, Caxton Hall, Westminster, S.W. Mr. L. W. J. Costello, "The Law Relating to Engineering." (Lecture IV.)

London Institution, Finsbury-circus, E.C., 5 p.m. Rev. T. T. Norgate, "Corsica, the Land of the Vendetta."

TUESDAY, NOVEMBER 22...Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. H. K. G. Bamber, "Portland Cement, and the Question of its Aeration."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. S. E. Fincham, "The Dauphiné District of Southern France, with Notes on the Palace of Versailles."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Mr. J. Hudson, "Plants in Congenial Positions."

WEDNESDAY, NOVEMBER 23...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Sir Henry Hardinge Cunynghame, "Methods of Detecting Fire-Damp in Mines."

Geological, Burlington House, W., 8 p.m.

Royal Society of Literature, 20, Hanover-square, W., 5 p.m. Rev. J. Arbuthnot Nairn, "Illustrations from Papyri of the Manners and Customs of Ancient Egypt."

British Astronomical, Sion College, Victoria Embankment, E.C., 5 p.m.

THURSDAY, NOVEMBER 24...Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

London Institution, Finsbury Circus, E.C., 6 p.m. Mr. E. Markham Lee, "Chopin—the Man and his Music."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. C. Phillips, "X Rays in Theory and Practice."

Electrical Engineers, Victoria Embankment, W.C., 8 p.m. Mr. H. T. Harrison, "Street Lighting by Modern Electric Lamps."

FRIDAY, NOVEMBER 25...North-East Coast Inst. of Engineers and Shipbuilders, Newcastle-on-Tyne, 7.30 p.m.

Physical, Imperial College of Science, South Kensington, S.W., 5 p.m. 1. Dr. A. Russell, "The Electric Stress at which ionisation begins in air." 2. Dr. A. Griffiths, "On the measurement of a flow of water in a closed circuit by a method involving little or no statical friction." 3. Mr. J. S. Dow, "Exhibition of a surface brightness photometer." 4. Mr. L. F. Richardson, "The approximate solution of various boundary problems by surface integration combined with freehand graphs."

Journal of the Royal Society of Arts.

No. 3,027. VOL. LIX.

FRIDAY, NOVEMBER 25, 1910.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, NOVEMBER 28th, 8 p.m. (Cantor Lecture.) CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Industrial Pyrometry." (Lecture II.)

TUESDAY, NOVEMBER 29th, 4.30 p.m. (Colonial Section.) A. MONTGOMERY, M.A., F.G.S., State Mining Engineer to the Government of Western Australia, "The Progress and Prospects of Mining in Western Australia." Admiral Sir FREDERICK GEORGE DENHAN BEDFORD, G.C.B., late Governor of Western Australia, will preside.

WEDNESDAY, NOVEMBER 30th, 8 p.m. (Ordinary Meeting.) CAMPBELL P. OGILVIE, "Argentina from a British Point of View." Sir ALEXANDER HENDERSON, Bart., will preside. (The paper will be illustrated with lantern slides and cinematograph views.)

Further particulars of the Society's meetings will be found at the end of this number.

"INDUSTRIAL ENGLAND IN 1754."

In accordance with a resolution passed by the Council* the Paper read before the Society on April 20th, 1910, by the Secretary, has now been published in book form, with corrections and additions, under the title "Industrial England in the Middle of the Eighteenth Century." The price of the book is 5*s.* net, and copies may be obtained of the publisher, Mr. John Murray, Albemarle-street, London, W.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

Wednesday, November 23rd, 1910; the Hon. RICHARD CLERE PARSONS, M.A., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Barrington, Mrs. Russell, 4, Melbury-road, Kensington, W.

Bruce-Williams, M., Green Hurst, Beaconsfield, Bucks.

Hepburn, Edward, Monkridge, Sidcup, Kent.

Jacobson, Richard, 70, Shoe-lane, E.C.

Laing, Miss Theresa T., Etal-manor, Cornhill-on-Tweed, R.S.O., N.B.

Wentworth-Sheilds, Francis Ernest, M.Inst.C.E., Docks Engineer's Office, Southampton.

Wolfenden, Stuart J. Norris, Conservative Club, St. James's-street, S.W.

The paper read was—

METHODS OF DETECTING FIRE-DAMP IN MINES.

By SIR HENRY H. CUNYNGHAME, K.C.B.

The object of my Paper is to give a brief description of the principal methods of detecting fire-damp in mines.

You are no doubt aware that in early mining fire-damp, or fire-vapour, constituted a very dreaded danger, and that the invention of Sir Humphry Davy first afforded a means of carrying a light with safety into a fiery atmosphere. The principle of this lamp, as you know, is that copper-wire gauze acts as a sieve or filter to ignited gas, the heat being abstracted by the gauze and remaining in it, and thus the flame is extinguished.

For many years explosions in mines were put down to fire-damp. Gradually, however, the idea started by Faraday gained ground, that though an ignition of fire-damp might originate an explosion, yet the explosion itself was due to coal-dust. And after the Tylorstown disaster it was shown that the majority of men killed in these explosions do not perish from fire, but die from the effects of the poisonous after-damp. So that we now know that when there is a big explosion—as at Whitehaven—it is not an explosion of fire-damp killing men by its violence, but an explosion of coal-dust which destroys its victims by poison. Ninety per cent. of the men die in this manner: fortunately the death is a painless one.

* See Report of the Council, *Journal*, vol. lviii., p. 753.

Although fire-damp does not play the part in mine explosions which was once supposed, yet it is still very important to keep it under. Small local explosions of fire-damp are the only ones which now occur—for it would be impossible for a mine to get filled from end to end with fire-damp without discovery—yet these small local explosions injure and kill working parties, and they may originate formidable explosions by setting on fire the impalpable coal-dust that is always floating about. Hence it is absolutely necessary to keep mines clear of fire-damp. Most of the ventilating air sent into a colliery is directed to this aim, for though, of course, it is necessary that men should have pure air to work in, it is far more necessary still that the fire-damp should be cleared away and carried up the up-cast shaft, which is always more or less impregnated with fire-damp.

Fire-damp—or to use its chemical name, methane — is a compound of carbon and hydrogen. It is formed wherever vegetable fibre is decaying under water. It is given off from coal, which is only a fossil vegetable. It is also given off from marshy ponds, and bubbles of it arising from them can be set on fire.

In mines such as the hematite mines, where vast quantities of pit-wood are accumulated, often soaked in water, fire-damp has been found, although there is no trace of coal in the vicinity. Even small explosions have occurred in such mines.

But the chief source of fire-damp is coal. When coal is heated in a retort gases are driven off which consist principally of methane, and are used for burning in ordinary life. Coal-gas and methane are, therefore, very similar in composition and in behaviour.

The amount of methane which, if present in air, will make it explosive varies from about 6½ to 18 per cent. With less than 6½ per cent. there is not enough methane to carry on the combustion. With more than 18 per cent. of methane there is not enough oxygen to carry on the combustion. The most explosive mixture is about half-way between these extremes—namely, about 10 per cent. In this case, theoretically, the whole of the methane and all the oxygen in the air ought to be united, causing as products steam and carbonic acid, with traces also of carbon monoxide. And the volume of the resultant gases ought, when cool, to be diminished by double the proportion of the methane originally present. Thus, if 5 per cent. of methane is added to a given volume of air, then, when the methane is burned up with some of the oxygen of that air and cooled again, the resulting volume will be 10 per cent. less than it was before.

The dangers of methane render it very desirable that a means should be found of detecting its presence. This, of course, can only be done by taking advantage of some physical properties by which methane differs from air so as to afford a guide to its recognition.

We can detect coal-gas by reason of the smell, due to some volatile constituents which are released by the heat of the gas-retorts. But pure methane has no smell, and this method —which would, if it were practicable, be the simplest—is not practicable. Methane, if heated, has no effect, or practically no effect, on man. One can, therefore, breathe perfectly in an explosive atmosphere and be quite unaware of its danger. But methane is much lighter than air. Here, then, we have a possible means of detection. For instance, a very light balloon, filled with air heavily contaminated with methane, would rise in ordinary air, but so feebly that this method is not applicable to the detection of the small quantities which, as we have seen above, are explosive.

There is, however, a method of making use of the lightness of methane which is both ingenious and to some extent practicable.

In order to explain it I must say a few words on the nature of gases. I address them, of course, not to scientific chemists, but to that portion of my audience whose life has been passed in a contest rather with practical questions than with theoretic ones.

The old notion of a gas was that of an elastic mobile body, something like a sponge which could be squeezed into a smaller space, but which, if released, would expand somewhat as does a hair pillow. But, unlike a sponge, the gas would, if free, expand indefinitely, so that this old elastic theory of gases, which accorded very well with observed tables of volumes and pressures, presented in theory considerable difficulty, for if a gas could expand indefinitely and yet were a uniform homogeneous body, how could we imagine a cubic inch of gas when liberated filling the universe? The idea seemed absurd of a body which, without addition to its mass, could swell up absolutely without any limit at all, so as to fill an infinite space.

Besides, it was observed that gases had an extraordinary power of packing themselves into one another, so that two gases expanding against one another, if allowed to mix, did not behave like two spring mattresses, but stored them-

selves into one another as if there were an interpenetration of the parts without addition of volume. Besides this, when gases were reduced to a condition of high rarification and electrified, they behaved in an extraordinary manner, which made them rather resemble swarms of meteors than elastic cushions.

These considerations arose at a time when new light was being thrown on the nature of matter. Instead of considering matter as solid stuff capable of being indefinitely divided, chemical science rendered it necessary to consider matter as composed of atoms and molecules, so as to be like, say, the hard roe of a herring. Of course, each little atom on this view could not be considered like a marble. For then you would ask, Of what is the marble composed? It was necessary, therefore, to treat the atom as an impalpable small field of force, of the nature of which we are quite ignorant: it might be a whirl in an ether, but was not severable into other similar whirls; it possessed a volume, a size, and a weight of its own, but was not resolvable into two atoms because it was rather of the nature of a centre of force exerting its influences at small fixed distances which gave it the power of occupying space and yet without the capability of being divided.

Once the existence of these atoms was admitted it became easy to consider solids as made up of a quantity of them bound together, liquids to be a quantity of them in contact but capable of sliding like marbles in a bag, and then the step became easy to consider a gas as a quantity of such atoms which had by means of motion—or, in other words, heat—being communicated to them acquired the power of flying and were always engaged in shooting about in all directions, ricocheting against one another, and against the walls of the chamber in which they were confined, just like a quantity of excited flies contained in a bottle.

In this way the expansibility of gas could be explained. The pressure exerted by gases against the sides of their containers was accounted for. The fact that gases when heated—*i.e.*, when motion is poured into them—exert greater pressure and try to expand, was explained by the greater velocity of the flight of the molecules, and, in fact, the laws affecting gases—the laws of Boyle, of Marriotte, and others—all found a ready explanation, and it was possible to compute the number of molecules in a certain volume, their velocity, and the average distance each could fly without hitting up against another molecule.

On this theory we must compare air to a number of heavy flies, and methane to a swarm of light, quicker-flying mosquitoes. Now, suppose we bring two chambers, one containing air molecules and the other containing methane molecules, into contact and remove the partition between them. At once they will begin to diffuse into one another. The flies will invade the realm of the mosquitoes, the mosquitoes will invade the realm of the flies. And which will do it quickest? Clearly those who can fly the quickest. So that it is certain that a mosquito or two will have got right through the realm of the flies and hit the outer boundary quicker than the first fly will have penetrated the mosquitoes.

How fast this will take place depends on the numbers of flies and mosquitoes that there are, and how closely they are packed, as well as how rapidly they fly. If we want to measure this rapidity we must somehow impede their motions, for they mix so quickly when free that observation cannot follow them. Hence, then, instead of letting the swarms come into contact we put a grating between them, through which they can only get slowly, and by this means we can render the measurement of their progress possible.

In practice this is done by putting the two gases into separate chambers divided by a porous diaphragm of plaster of Paris which, though to our grosser senses it appears a solid, is not a solid but a sieve containing numberless passages through which enterprising mosquitoes and flies will find their way, urged in their progress by their own initial velocities and the kicks of their comrades behind. The temperature of the gases will, of course, remain uniform, or, if it in any way suffered by the passage of the molecules through the diaphragm, it would be restored by communication of heat from the air around. Hence the motion of the molecules which is the cause of the heat will remain unchanged.

After a short time, therefore, it will be found that in each compartment there are both mosquitoes and flies, but that the proportion of mosquitoes that have passed into the fly compartment is greater than the proportion of flies that have gone the other way. Whence one compartment must be more full than the other, and since in both the velocity of the flies and mosquitoes is the same, the pressure must be greater in that compartment, owing to the increased battery of the inmates against the sides. Hence, if each compartment be fitted with a barometer, we should find the reading on the side which contained methane lower than

the other. By this means the presence of methane might be established.

This method, however, is attended with disadvantages. Fresh uncontaminated air must be brought in the instrument from the surface, and when one experiment is completed this air must be renewed. Again, impurities other than methane may obscure the results. Thus, if carbonic acid is present, it will produce an effect the reverse of methane, and consequently a mixture of air, methane and carbonic acid may be taken for pure air.

An invention has been made by which a small thin column of mercury is substituted for the barometer.

The next method is to use the pitch of an organ pipe. Of course, in contaminated air an organ pipe of a particular pitch will sound a different note from that which it gives in pure air. Accordingly the difference of note may be observed and conclusions drawn.

We now pass to electrical methods, dependent on the effect of burning methane in contact with a red-hot wire. The proposal of this is due to Mr. Liveing, son of the well-known chemist. If two platinum wires of equal length and size are both heated by the same current, and to the same degree, that one which is in air will exhibit much less of a glow than that which is in the mixture of air and methane. The difference can be estimated by the eye and the methane judged. An improvement on this instrument has been made by Mr. Arnold Philip for the Admiralty, or rather a modification. This consists in measuring the increased resistance of a heated platinum wire when immersed in an atmosphere containing methane. I am not in a position to say how this works. The criticism I should make upon it is that the platinum wire may become filled with occluded air, and hence vary in the degree of its resistance; but I think this might probably be overcome.

The next instrument depends upon the refraction under air and methane. The velocity of light in the different media will be different, and therefore by the proper arrangement of rays of light defraction bands may be introduced as shown in the diagram before you.

The above methods have been briefly reviewed in order to make it clear that they afford a possible basis for future machines. None of them have been very successful hitherto, and hence in practical use it has been necessary to fall back on one of the oldest methods, namely, the behaviour of flame when subjected to the influence of methane in the atmosphere in which it is burned.

A candle or lamp flame consists of burning gas which is distilled from melted wax or from oil sucked up into the wick. The flame consists of two parts, the body and the mantle. The body is usually yellow, the mantle is a very pale ghost-like colour. When the flame is brought into air containing any combustible gas or vapour, such as methane, a cap appears over the mantle. This cap is usually very pale, so pale that it can be distinguished only with difficulty. Its exterior edge is near the mantle, and owing to the brightness of the body it is generally impossible to see, unless the lamp is turned down so as to make the whole flame as small as possible. Thus, by turning the light very low, it is possible to see a cap when there is 1½ or 2 per cent. of methane in the air, and to see it clearly when the amount rises to 3 or 4 or 5 per cent.

The more volatile the oil, the better the flame is seen. Thus naphtha or benzine spirit shows the cap better than colza. And, again, the more pale and colourless the flame the better can the cap be recognised, hence flames of alcohol or gas are very suitable. With the Clowes lamp 1 per cent. of methane can be detected.

The character and height of the cap are indicative of the amount of gas present. With 1½ per cent. the cap forms a truncated cone, with 2 per cent. it forms a pointed triangle, which becomes more acute as the percentage rises.

In order to facilitate the detection of firedamp, the Home Department has issued cards containing coloured drawings of flames showing the caps upon them.

It only remains for me to describe and show an improvement introduced into safety lamps by myself and Professor Cadman of Birmingham, whereby the cap on flames is rendered more visible.

Everyone knows the effect produced by introducing into a Bunsen gas flame, or into an alcohol flame, a wire dipped in a salt of sodium. The invisible flame is at once turned to a bright yellow colour and becomes visible.

The familiar snapdragon is an instance of a similar phenomenon.

Exactly the same thing can be done with a miner's lamp. By mounting a small piece of asbestos steeped in carbonate of soda so as to be capable of being introduced into the flame of a miner's lamp, a gas cap is rendered easy to see.

In addition, there is the great advantage that it is not necessary to turn the light down, and so no danger that the light will go out.

It lastly remains only to describe the most accurate method of detecting gas in mines, but one which takes a little time, and is not suited for use by miners. I mean the method of gas analysis.

The plan is to take a measured quantity of the suspected air, and to pass it into a chamber in which is a red-hot platinum wire. The methane is thus burned out of it. The air is then sent back into the original chamber, free of methane, but containing carbonic acid, and its volume is again measured.

The apparatus on the table is the design of Dr. Haldane, and is being generally employed.

The value of this method is, of course, very great for checking results otherwise obtained.

These are the means at present in practical use for the detection and estimation of fire-damp. They are not yet perfect, but they are daily being improved, and with a very moderate degree of training ought to render the measurement of methane a simple and rapid matter.

[The paper was illustrated by numerous experiments which had been prepared by Professor John Cadman of Birmingham University.]

DISCUSSION.

The CHAIRMAN, in opening the discussion, thought all present would agree that the experiments they had seen were of a most interesting nature, because the subject of Fire-Damp and Explosions in Mines was of such very great importance that any improvement that could be made in detecting fire-damp and explosive gases so as to prevent explosions occurring must be of benefit to the community. He had been very much struck with the author's remark that all the beautiful methods that had been invented for detecting gases were satisfactory only up to a certain point, because it was of great importance not to induce a miner to rely too much upon a method of detecting explosive gases, as he might thereby become foolhardy and might think there was no gas in a mine, when all the time there might be a sufficient percentage present to produce an explosion. The author was, he thought, very much to be congratulated upon the interest he took in the question, because, occupying the important position he did at the Home Office, it was of enormous benefit to the general public to have such a scientific man taking so much interest in such an important subject.

Dr. J. S. HALDANE, F.R.S., said he had watched the beautiful experiments which the author had made with the very greatest pleasure, because they were entirely new to him. The simile of flies in a bottle was an extraordinarily vivid and apt one, because it exactly conveyed to the ordinary mind what physicists and chemists believed was happening with the molecules of gas, and the same remark applied to the simile of bluebottles for the carbonic acid, and mosquitoes for the fire-damp. He thought those comparisons would become classical, and that they would frequently be heard in the future in other lectures. It seemed to him that the new method of testing with sodium, devised by the author and Professor Cadman, made it practicable to carry out testing for a gas in ordinary mines in a far more thorough way than had been the case before. He knew well what it was to have the fear of losing one's light in a mine. He was ashamed to say he often lost his light, and, were it not for the fact that somebody was with him who had a light, he would have been left in darkness. The method described, however, made it possible for the official inspecting a mine to examine at any moment for gas with comfort and great celerity. It was an extraordinary improvement on the old method of testing, and left no excuse for not examining the airways of a mine thoroughly.

Mr. T. RATCLIFFE ELLIS said that in the popular view accidents in mines were generally attributed to explosions of gas. Of course there were many other causes, but that was considered to be the one against which special precautions required to be taken. That it was extremely dangerous, he thought, few people would deny. Every attempt was made in mines to lessen that danger by having ventilation which was sufficient to clear off the gases. An examination was made by officials before the men went to work, once or twice during the time they were at work, and it was also the duty of the workman himself to examine his working place to see if it was free from gas. Upon the care with which that examination was made must very largely depend the safety of the men employed in the mine; and any advance which could be made in the direction of producing a lamp which would more readily find gas, and was not subject to the disadvantages which had been pointed out of the lamp being extinguished, would go a long way in the direction of saving life and lessening dangers in mines. As the author had pointed out, the flame must be lowered in order that the gas might be seen, and although two per cent. or two and a half per cent. might not in itself be dangerous, it indicated a state of things which required careful watching. He thought it might be the case that the fear of losing the light did sometimes interfere with that carefulness in the examination for gas which was necessary. He was not competent to pass any opinion upon the general merits of the lamp, but inasmuch as it enabled a much smaller quantity of gas to be distinguished without the chance of losing the light, it seemed to him it was a very great advance on the present safety lamp.

Professor JOHN CADMAN said the author had referred to the work which it was his (Professor Cadman's) privilege to do in conjunction with him in connection with the investigation of the flames of safety lamps, and had mentioned the lamp-chamber which had been constructed in Birmingham University for the purpose of making an examination which was as realistic as possible. The author and himself were enclosed in that chamber, and fire-damp, which had been previously generated, was passed into the chamber in measured quantities in order to get various percentages. His own portion of the work was to provide mixtures in which both the author and himself sat, and to analyse them periodically to see that the proper standard of mixture was being obtained. At the same time, the author painted the beautiful pictures which he believed many of those present had already seen. When the idea of the sodium occurred to the author, the top was taken off the lamp, after a very careful test, and after he had assured Sir Henry that the Mines Regulation Act did not apply to the place in which they were sitting! An interesting feature was that they were locked in the chamber, there being nothing but a small pipe-hole leading from the outside, and they suddenly discovered they had no sodium. The passing of a bottle of sodium through the door would have meant that the mixture would be altered; but Sir Henry, who was, he believed, at the time a martyr to indigestion, produced some tablets of sodium carbonate from his pocket, and by taking one of the lamps to pieces and getting some asbestos from it they were able to produce a sodium flame. Then it was suddenly found that the oxygen was getting rather low, as both the author and himself began to pant slightly, and they also knew that as the lights would be going out in a few moments the whole experiment would be at an end. The author immediately suggested that some oxygen might be introduced, and he (Professor Cadman) therefore telephoned through the wall for the assistant to blow some oxygen into the chamber. That was immediately done, so that the air in the chamber was made breathable again and it was possible to continue the experiment. He mentioned those facts to show the enthusiasm with which the author entered into that kind of work, and he thought the mining public did not sufficiently realise the very valuable work which Sir Henry did on its behalf. It had been a very great pleasure to him to assist the author in any way in providing the apparatus to illustrate such an interesting lecture.

Mr. LEON GASTER said that he was present at the recent Congress of Hygiene at Brussels, which was attended by many factory inspectors, doctors, and legislators, and he had been particularly struck by the admiration expressed on all sides for the enthusiasm with which English scientists were carrying out investigations into such subjects as fire-damp and lead-poisoning; while Dr. Haldane's method of testing in caisson work had been accepted as the best in existence. The author had mentioned a very important point when he suggested that the sight of all the miners ought to be examined. He would like to see it part of the law that all those who had to be relied upon in connection with mining work should have their eyesight tested for the purpose of ascertaining whether they could detect the cap on the flame denoting the presence of gas.

Mr. W. C. BLACKETT desired to say a few words from the practical side compared with the scientific side dealt with by the author, as for thirty years he had made his living in mines, and had studied them from all points of view. Coming, as he did, from the north of England, he would like to say that no body of coal-owners and managers more recognised the efforts of the author than those in that part of the country. It was the scientific point of view that methane had no smell, but the gas usually given off in mines which was scientifically called methane had a faint smell. He did not say that that smell was of any great value, because it was only when it was pretty strong that one could be sure of detecting it; but all men who had studied the subject down the mine would unite in saying that methane, as found in the mine, had a certain smell which was observable by certain noses. With regard to the practical value of the appliances which had been shown, he was inclined to be a little sceptical. By the time the appliance gave the alarm to the manager, or the over-man, the real danger had taken place in a remote part of the mine; it was as likely to be in a working place as anywhere else, and therefore they were again thrown back on the safety lamp of the miner. The real guard against the danger of gas in a mine was the ordinary safety lamp of the miner, and so far as he could see at present, it was likely to remain so until some entirely different form of light was adopted. Coming to the question of caps, he had heard the statement made by one individual that half an inch of cap betokened great danger, because it indicated a certain definite percentage of fire-damp; while within a very short time he had heard another individual say that half an inch of cap betokened no danger at all. The truth was that half an inch of cap did not mean a definite percentage of gas, inasmuch as if the flame of the safety lamp was reduced to the smallest speck of blue for testing the gas, a less cap was obtained than if the smallest speck of yellow light, such as the author used, was present, the one representing four per cent. and the other under three per cent. The loose way of speaking of the cap was responsible for that difference. Dealing with the question of the eyesight of miners, unfortunately his own sight had been put to very severe trial, and he

could not see as well at present as he could years ago, but he found it easy to overcome that slight difficulty. By applying a strong lens to the lamp it was possible to see the cap very much more easily than without its aid. The use of sodium in the safety lamp as suggested by Dr. Cadman and the author, was an excellent idea, even from a practical point of view, but after a certain number of applications its virtues disappeared.

In the old days before safety lamps were invented men had to go into mines, where gas existed, with ordinary candles. Those men carried their lives in their hands, but they were a deal better men at looking for gas than the miners of the present day, because they did their work more carefully. Men nowadays could sometimes be looked after too carefully. Things were made too soft and too luxurious for them, and they did not do their work as well as they used to for that reason. The miner shaded the candle with his hands, and he could tell when he began to get into a dangerous zone by the pulling up of the flame. He recently came across an appliance that a man had designed in the north of England as another among the many instruments for detecting fire-damp. The length of the ordinary flame of the safety lamp in pure air was increased when introduced into a small percentage of fire-damp, and this increase could be measured by means of a scale in the lamp. The truth of the matter was that they were driven back to the common ordinary safety lamp for the safety of the mines as they existed to-day. It was no good having skilled men going about in mines with fine apparatus which was used in one or two places, and then to leave the miner for the rest of his hours of work in his working place with nothing else to guard him than the ordinary safety lamp. That was the weakest link in the chain. Mine-managers might send as many apparatus as they liked into the pit; but if they left the man to work with the safety lamp, it was on the safety lamp they depended.

If all the talent of scientific people were devoted to producing a safety lamp which would go out when it reached the standard of ventilation, so that the miner was left in darkness, the most useful apparatus that could possibly be employed in mines would be evolved—a common or garden safety lamp that would go out when, say, three per cent. of gas was reached. Another interesting point was as to where they should look for gas in a pit. It was useless for a man to describe how wet a room was if he put his head under a small trickle of water coming from a tap in the corner of the room, because that would not be a very dangerous quantity of water. Exactly the same applied to a mine, except that the gas in the mine, instead of coming out of the side of the wall and falling as the water did, came out of the side of the wall and rose, and it was possible with any of the appliances which had been shown to have an indication of gas close in the face, right up in the roof, which would betoken a dangerous quantity if it were somewhere else, but which was not dangerous in that particular point. All those things ought to be considered in the interests of the harassed officials of mines. Every possible consideration ought to be given to mine-managers and mine-overmen in view of the great responsibilities that rested upon them, and the extremely onerous duties they had to perform, because after all they were only human beings.

Sir Henry Cunynghame, in reply to Mr. Blackett, said it was quite true that when a candle was put into an atmosphere in which there was methane the flame lengthened. Mr. Patterson had invented an apparatus in which a magic-lantern representation was passed through a lens on to a sheet, an observation being taken of how high the flame rose above a standard amount. The difficulty arose, what the standard amount was to be. The lamp had to be turned up first of all to the standard amount A, and an observation had to be made of how much higher the gas made it go. Turning it up to the standard A involved having the lamp trimmed in a particular way, and the admission of air quite free from methane. That gave the standard. If the lamp was taken from air that had no methane, into air that contained methane, the amount of the rise of the lamp could be proportionately obtained, and it afforded a fair method of getting the test, but the difficulty was, how were they to be sure of the standard? How were they to be sure that in the roadway, for instance, away from the dangerous places, air was obtained free from methane? If they could be sure of that, they had a standard; if not, they had not. That always appeared to him to be a difficulty in the use of a lamp of that form. The remarks Mr. Blackett had made with regard to lenses were excellent, but the reason why a lens was not of itself sufficient was that the light must be turned down. One of the chief objects in the new lamp designed by Professor Cadman and himself, was not to force the miner to turn his lamp down. The lamp could be kept up, and there was no danger of losing the light; and that consequently remained an advantage which all lamps possessed in trying to make the cap luminous. Mr. Blackett would be the first to admit that the turning down of the lamp was a decided disadvantage, particularly if the lamp wick happened to be dirty and had been alight for some time; it made men shirk, if they could, the duty of testing for gas. So that although it was quite true that it was an excellent thing to have a lens to add to the lamp, he still thought it was desirable that, whatever means were adopted in the future for detecting gas, it should be done without having to lower the flame. Whilst he had the greatest admiration for any apparatus that could be profitably used by overseers and overmen, he thought it very desirable that an apparatus should be in the hands of a great many

of the workmen which could be fixed on to the ordinary lamp they carried about, and used, if the occasion arose, at once without in any way detracting from the use of the lamp as an ordinary light-giver. If it could be fixed into the lamp it was a handy little apparatus by which the presence of gas could be detected immediately. Professor Cadman and himself had made a great many experiments with regard to the burning off of the sodium, and found that sixty hours' continuous burning could be obtained before the sodium was exhausted; so that its durability was manifest when one bore in mind that a test lasted only about three minutes. Uralite soaked in carbonate of soda was the best substance to use, and he believed he was safe in saying that once a piece had been soaked it would always produce a flame. If it were used for years he believed it would still show one, though he admitted it was better to have a fresh piece. Another advantage of the new appliance was that it could be used in both ways. He had taken the new lamp down into mines, and found that half per cent. could be seen without any difficulty at all; and it took a very keen eye indeed to see half per cent. with an ordinary miners' lamp. He had often turned the new lamp off and turned the old one on in order to compare the two results, and it was always possible to fall back upon testing in the ordinary way.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Sir Henry Cunynghame for his interesting Paper, and to Professor Cadman for his valuable aid in the experimental illustrations.

RUSSIAN FURS.

For the past two centuries a trade in furs has been carried on between Russia and other countries. London is the largest and most important fur-distributing point in the world, followed by Leipzig, a large market for European, American and Asiatic furs; Nizhni Novgorod, renowned for its annual fairs, which are visited by thousands of buyers and sellers from Europe and America; Irbit, also noted for its annual fur fair; Kasan, whose trade is almost exclusively with the dealers from Siberia; Kiachta, near the Siberian-Chinese boundary, and Astrakhan, at the mouth of the Volga, noted as the distributing point for Persian lamb skins, gathered from Persia, Syria and Bokhara, and worn throughout the civilised world. Tiflis, Kharkov, Baku and Archangel are also important outlets for furs produced in their respective provinces. The principal furs produced in Russia are the ermine, sable, sea otter, beaver, mink, musquash (musk-rat), squirrel, fox, skunk, marmot, weasel, badger, minever, rabbit and hare. Ermine is the highest priced of all furs, and although worn in general is regarded as a "royal fur." It is found in the north of Russia and Scandinavia, the most excellent quality coming from Ischim and Barabinsk, Siberia. According to the American Consul at Moscow, the ermine becomes pure white in winter in those snow-covered regions, where, if it retained its summer hue, the fact would render it an easy prey to its enemies. The tip of the tail alone remains black. Trapping ermine is carried on in winter, of necessity; in some localities they are shot with arrows in order to prevent the possibility of damaging the beautiful and costly coat. The skins rarely measure over a foot in length, and are disposed of by the trappers in lots of forty. The Russian sable, derived from the marten, while not so valuable as the ermine, is costly enough to prevent its becoming common. The skins range in size from fifteen to twenty inches in length, and from five to eight inches in breadth. In a genuine sable the outer covering of hair is especially delicate in quality and beautiful in colour, it being of a rich blue tint, varying from one and a half to two and a half inches in length, while the felt is very soft, but at the same time durable. The value and grades vary according to the district in which they are found, the highest quality being found in Yakutsk, the next best in the Lena River district, while the inferior are bought in the Lower Amur region. The Kamtchatka sable, more brown in colour than others, is regarded highly by the Russians. The sables are disposed of mainly on the London market, where they are distributed for sale in Europe and the United States. The tails are utilised for artists' brushes, but many so-called sable-hair brushes are made from the tail-hair of the Kolinski or Tartar sable. Mink furs are also sold to those unacquainted with these articles for sables, and so are the Tartar sables, which are brought in large quantities from Tartary and Siberia. The Tartar sable is a member of the squirrel family, and, while the coat is brilliantly yellow in its nature state, it is dyed to resemble the colour of the genuine sable, and can hardly be distinguished in many instances. Sable is also imitated by some exporters in Russia in the sale of dyed hare, rabbit, musk-rat and marmot skins, but the imposture is detected by legitimate and reliable dealers. The sea otter fur is highly prized in Russia, where it is used in the manufacture of caps for men and women, and for trimmings, coat collars, and the like. The sea otter is found in Kamtchatka, and is captured in large quantities by hunters and trappers. Large numbers of sea otter furs are also imported into Russia from Canada. It has been estimated that more than 30,000,000 squirrel skins find their way from Russia each year to the markets of the world. The grey fur is in demand for general uses, for cloak and coat linings. Another member of the squirrel family found in eastern Siberia, regarded with even more favour than the grey variety, is the blue squirrel, whose colour varies from dark to light, according to the season of the year. The tails are longer and more bushy than those of the grey squirrel, and are made up in boas, or used for artists' brushes. The beaver skin, while produced in some

parts of Russia, is mainly imported from North America. The musk-rat is found in large quantities along the Volga and its tributaries, and is considered the easiest fur-bearing animal to trap. The mink's beautiful brown coat is much in demand, the fur being especially suitable for muffs and other articles. In point of commercial value the fox is only surpassed by the sable. The Russian fox has not the high quality that is found in those brought from Labrador; the silver fox fur is in universal demand. Rabbit and hare skins are to be found in all the cheap markets, but their commercial importance ranks high because of their universal use among those who cannot afford high-class skins. The fur of the white Arctic hare is often disposed of as genuine fox, but an expert can easily tell the difference. The value of furs exported from Russia in 1909 amounted to £1,250,000.

THE AMERICAN CHRISTMAS-TREE INDUSTRY.

The United States requires annually not less than 4,000,000 Christmas trees, and there is little doubt that the present indiscriminate cropping, every year, of many young evergreens for Christmas trees has produced, in many cases, a bad effect on the future timber supply. If the woodlands were under a proper forestry management, no harm would be done, for the yearly thinning of the forests would satisfy even a greater demand for Christmas trees than now exists. It is frequently found, in Maine and the Adirondacks, the principal sources of supply of Christmas trees, that there are as many as 50,000 to 100,000 young seedlings on an acre. The use of small evergreens for Christmas trees offers, therefore, an excellent opportunity for the improvement of the forest by thinning. Every winter, at the time Christmas trees are beginning to be in demand, thousands of spruce and balsam fir trees are cut throughout Maine, New Hampshire, Vermont, and New York, for lumber and pulp. The trees are never taken below four inches in diameter in the top. Thousands of the tops of spruce and balsam fir trees are consequently left every year in the woods to rot, and serve as fuel, when they would make excellent Christmas trees. According to the United States Department of Agriculture, practically all conifers can be, and are, used as Christmas trees, but the most popular ones are the firs, spruces, and to a less extent the pines and cedars. The use of one or other evergreen for this purpose, depends frequently upon its accessibility, particularly in the mountainous districts of the country. Thus, for instance, in Colorado, where fir is abundant, but grows at high altitudes and therefore is difficult to get out, the lodgepole pine growing at the foot of the mountains, and the Douglas spruce, are more frequently used than the fir. The latter is undoubtedly the Christmas tree *par excellence*, especially in the north-eastern and Lake states. The spruce vies with the fir in popularity as a Christmas tree, but as a rule, in the south and west, they grow at high altitudes, which makes them also difficult to get at, and are therefore replaced by less suitable, but more accessible conifers. Black spruce is the tree chiefly found in New York and Philadelphia. Throughout the States of Illinois and Ohio, nurserymen supply the local demand with nursery-grown Norway spruce. The pines are in great demand for Christmas trees when fir and spruce are not available, or are only to be had at a high price. Throughout Maryland, Virginia, and in Washington, the scrub pine finds a way into many homes for use in this capacity, while in southern Wyoming the lodgepole pine is almost the only species available for Christmas trees. The centre of the Christmas-tree industry lies in the large cities of the east. New York City and the New England States consume 1,500,000 trees, or nearly half of all the output. Maine, New Hampshire, the Berkshire Hills in Massachusetts, the Adirondacks, and the Catskills in New York, are the sources of supply for New York, Philadelphia, and Boston, and even for Baltimore and Washington. The swamps of Michigan, Wisconsin, and Minnesota furnish the markets of Chicago, St. Paul, and Minneapolis. The sizes of Christmas trees vary from five to thirty-five feet in height. Usually short-pointed, stocky trees with thick branches at the base of each annual growth, are the most sought for. The sale price varies, being dependent upon the demand and supply. Ordinarily small trees, five to six feet high, are sold for about one shilling in the city markets, while a tree from six to ten feet high brings four shillings or more, according to its symmetry. Large, shapely trees are sold in New York City at from one pound to six pounds each, and trees thirty-five feet high bring as much as seven pounds each. The average run of prices is from a minimum of one shilling to a maximum of one pound for a tree. There is very little profit in the business for those who furnish the material. These are mostly farmers who look upon the trees as a gift of Nature, and in selling them consider only the labour of cutting and hauling, and not the labour and expense required to grow the trees. For trees which in the cities bring one shilling, the farmers get about twopence halfpenny. Trees sold in the cities for about six shillings a-piece, bring them only about sevenpence halfpenny. This, of course, only refers to the large cities. In small towns the demand is supplied by the farmers directly, who cut down the trees and hawk them from house to house. When the market is not glutted, the dealers make large profits, sometimes as much as two hundred or three hundred per cent. on their outlay, but when the supply exceeds the demand they are apt to suffer losses, and frequently resort to the destruction of many thousands of trees in order to keep up prices. Balsam firs of the sizes used for Christmas trees can be grown in about fifteen years. Allowing for each tree a space six feet by seven for a good development of the crown, there may be expected at this age over one thousand

trees, of sizes varying from eight to fifteen feet in height, on an acre. Such trees bring in the cities from six shillings to twelve shillings each.

YERBA MATÉ, OR PARAGUAY TEA.

Yerba maté, or Paraguay tea, is the daily household beverage of the masses of Paraguay, and it is consumed to a great extent also in Brazil and Argentina. It has been introduced into Europe, where its use is increasing. This tea is the product of a plant belonging to the species Ilex, an evergreen shrub or small tree, well known in western Europe. The leaves of this plant are carefully toasted near the place where they are gathered, all the skill required in producing the tea being applied in the process of toasting. This is necessary in order to dry the leaves thoroughly and evenly, without scorching or affecting their flavour by smoke. After toasting, the leaves are sent to the mill, where they are ground to fine powder and packed solidly into bags for market. According to the United States Consul at Asuncion, the tea is prepared for drinking in Paraguay in the same manner as ordinary tea, and may be taken with sugar, cream, lemon or brandy. The universal manner of drinking it is by sucking it through bombillas from maté cups. A bombilla is a tube, which may be of the simplicity of a mere pipe stem or an elaborately decorated silver or silver-mounted work of art. Maté cups vary in style from a simple little gourd to interesting specimens of local craftsmanship in silver. It is the custom to use a single maté cup, with its one bombilla, for an entire household, including all the visitors who may happen to be present, among whom it is passed like a pipe of peace. To refuse to partake would be a breach of etiquette. As an article of commerce, Yerba maté has steadily increased in importance, until it has become one of the leading exports of Paraguay, ranking fourth in value in 1909, when the exports amounted to £110,000. In July 1910 the entire product of the country for the year had been sold.

THE FRENCH WINE INDUSTRY.

It is evident that of late years the interest in viticulture has been steadily decreasing, with the result that in 1909 France imported 137,000,000 gallons of wine. The decreased production of wine in recent years is due, in part at least, to the law passed by the French Parliament on July 29th, 1907, regulating the watering and sugaring of wines, but this law had the wholesome effect of assuring a better quality of wine and higher prices for the producers, as well as effectively suppressing frauds which had sprung up in the making of wine. The area devoted to grapes in 1875 was 5,982,000 acres, and in 1909, 4,015,000 acres; the decrease between the years given has been steady and continuous. The abandonment of large tracts of vineyards in France on account of the ravages of the phylloxera is not distributed uniformly throughout the country, but is peculiar to only a number of Departments, in some of which viticulture has been almost entirely abandoned, while in others there is no apparent loss in the area devoted to that industry. The south-west portion of France, known as the "bassins" of the Garonne and Charente, comprising eleven Departments, has suffered a reduction of nearly 50 per cent. since 1875. Where the Departments of Charente counted 655,815 acres thirty-five years ago, to-day they have not more than 195,209 acres. The grape crop of Charente is not all converted into wine for present consumption, but is used almost exclusively for the production of cognac. The Midi region, which comprises the six Departments of the Mediterranean coast, has suffered only a small diminution of its vintage acreage, due to the fact that the planters, when the invasion of the phylloxera came, were able to combat it by substituting the more hardy American plants for the native vine. The wines of this region are known to be very thick and heavy. In the eastern portion of France, and the valleys of the Rhône, Beaujolais and Bourgogne, comprising six Departments, nearly one-fourth of the area has been abandoned by the wine-growers during this period of thirty-five years. In the valley of the Loire, comprising six Departments, there has been a falling-off of 383,000 acres, or about one-fifth during the thirty-five years' period. The United States Deputy Consul-General in Paris says that, notwithstanding the great diminution in the area of wine lands, the production has remained almost the same; in fact, for the last six years it has increased, owing largely to the healthy American plants which have been introduced into France, and which proved to have greater resisting powers against the ravages of the vine pests. It is interesting to note that, with the exception of 1875, the production of wine has steadily increased for the last sixty years. The region of the Midi, or the Mediterranean coast, comprising the Departments of the Pyrénées-Orientales, Aude, Herault, Gard, Bouches-du-Rhône, and Var, furnish more than one-half of the wine produced in France, their total production being about 645,000,000 gallons. The next most important is the south-west, or the valleys of the Garonne and the Charente, while the valleys of the Rhône, Beaujolais, and Bourgogne, in the eastern part of France, furnished nearly one-tenth of the wine harvest of 1909. Notwithstanding the abundant wine-harvests which France has enjoyed in the past, she has been compelled to import varying quantities of wine according to the supply at home. These importations have assumed significant figures from time to time, but have remained comparatively steady during the last three years. A large proportion of imported wines comes from Algeria, and as the wines from that place are very thin they are mixed with the heavy wines of the Midi. There are also considerable quantities of wines imported from Spain, Italy, and Portugal. The quantities of wine

imported into France during the last three years were as follows:—130,000,000 gallons in 1907; 152,000,000 gallons in 1908, and 137,000,000 gallons in 1909. There has been but little fluctuation in the amount of wine exported from France since 1888. In 1909 the quantity exported amounted to 55,000,000 gallons.

HOME INDUSTRIES.

The Cotton Crop.—The latest estimate of Messrs. Neill Brothers puts the American cotton crop of the present season at 11,600,000 bales, or a million bales more than last season's, but nearly two and a quarter million bales less than that of 1908-9. Three causes are given by Messrs. Neill Brothers for the comparatively small yield: (1) A long drought in Texas; (2) a late crop; (3) outside Texas, "a mysterious deterioration in the condition of the plant." Assuming that all the spindles of the world ordinarily using American cotton should work full time, Messrs. Neill estimate that they would want 13,550,000 bales this year. But, of course, full time everywhere is not to be expected, and if it occurred there would soon be a plethora of cotton goods. Fortunately the Indian and Egyptian crops are reported to be very good, and they will relieve the American crop. The Alexandria General Produce Association have estimated the Egyptian crop at 7,000,000 cantars, as against 5,000,000 cantars last season. On the whole, Lancashire spinners are taking a hopeful view of the outlook, and it is a reasonable expectation that though there must be some short time, it will be much less than in the past season.

The Uses of Cotton Seed.—The Publicity Committee of the Cottonseed Crushing Association of Georgia is doing its utmost to make known the use and importance of cotton seed products, and Dr. A. N. Soule, President of the Georgia State College of Agriculture, is writing a series of leaflets with the object of making the various properties of cotton seed better known. He says that cotton seed has risen in forty years from a position of uncertainty to being the basis of an industry of international importance. Its remarkable enhancement in value is not hard to understand when its chemical analysis is taken into consideration. Nearly 20 per cent. of cotton seed consists of oil, which, when properly refined, supplies the housewife with an admirable substitute for lard. "Through a wise provision of Nature," writes the doctor, "which man has been slow to appreciate, the oil consists entirely of carbon, nitrogen, and oxygen—three elements which plants secure chiefly from the air—and water which falls as rain." Dr. Soule continues in the same strain when describing the uses of cotton seed products:—"It is not difficult to see the important part which cotton seed plays now. and is destined to exercise in the future development of the live-stock industry of the south, and in the maintenance of soil fertility on that high basis essential to the production of maximum crops at a minimum cost."

Wool Supplies.—It looks as if wool supplies will be very ample this year. In the first four months of the present wool year, that is to say from July 1st to October 31st, the exports from Australia amounted to 463,000 bales against 391,000 bales for the corresponding months of last year, the increase being no less than 72,000 bales, of which 58,000 are to be credited to October alone. It is expected that this increase will be nearly doubled this month, and that the increase will be continuous until the end of the wool year, when it will probably amount to close upon 200,000 bales. Messrs. Dalgety report that, "The new clip is in some respects disappointing, for whilst the quality and softness of handle are above the average, many of the Riverina wools are shorter in staple, and all of them much more burry than last season. As regards condition, they vary considerably, but most of the clips offered by us to-day were no heavier than they were last year." It is reported from South Australia that Booboorowie South, belonging to Mr. A. S. Browne, and consisting of about 30,000 acres of splendid land, is about to be placed on the market, which means that the well-known clip of wool marked Browne, over Booboorowie, so popular for seventy years past with Bradford combers, will become a thing of the past. Mourak, too, which belonged to the late Colonel Browne, lost in the *Waratah*, is to be sold, and there will be an end of the famous Mourak clip of greasy Lincoln wool.

Carpet Yarn Contracts.—The judgment of Mr. Justice Hamilton in the action brought by the Chlidema Carpet Company of Kidderminster against a firm of spinners at Leicester for alleged breach of contract in the non-delivery of yarns and woollens clears up a point which has been the subject of much controversy. Mr. Justice Hamilton has ruled that "all open contracts in the section of the spinning trade connected with the supply of Kidderminster must be completed within one year." Mr. Justice Hamilton based his decision on the declaration in the Sale of Goods Act, which states that contracts must be completed "within a reasonable time." In the Bradford district specific periods have for some time been arranged in connection with delivery. A year certainly seems sufficiently liberal to meet the condition, "within a reasonable time."

The Shipbuilding Crisis.—The repeated refusal of the boiler-makers to authorise their leaders to give adequate guarantees that bargains will be observed in future, has led to an unprecedented situation. The employers say the lock-out must continue until such guarantees are given, the Society declares that it will not give these guarantees. The executive council of the Society wishes to give them but cannot without the authorisation of the men, which continues to be withheld. Hence deadlock. It looks as if the Society

must split up, since it can no longer make any contract with the federated employers. Possibly the considerable minority in favour of supporting their leaders will secede and form a new organisation of their own. The shipyards have had to pay off large numbers of wood-workers, for whom they can no longer find employment while the iron-work at the shipyards is at a standstill. Next we shall hear of the closing of the engine shops, which have been kept going in the expectation that the shipyard stoppage will soon be over. A number of steelworks have been closed down and the iron-works must follow suit. It is most lamentable. There is work in abundance to be done, yet all sorts of workers are idle because the majority of the boiler-makers refuse to be bound by the undertakings entered into on their behalf by their own leaders.

The Welsh Coal Strike.—It is to be feared that the Welsh coal strikes are not at an end. As soon as a settlement is reached in one district unrest develops into defiance in another. The strike in the Rhondda Valley was accompanied by scenes of violence, with which happily the country has been unfamiliar in recent years. The men marched from pit to pit compelling the engineers to cease work in the power-houses, many of which were wrecked. There was rioting for several days. Strangers were stoned, the shops looted, windows broken, stores distributed or scattered in the streets. Perhaps the most repulsive incident of all the lawless proceedings was the refusal of the rioters to permit the descent into the mines even of the ostlers, whose duty it was to feed the pit ponies. Hundreds of these poor animals in the various pits were left untended, without food or water, for four days. More wanton, deliberate, and callous cruelty it would be difficult to imagine.

Cheap Electric Lighting.—An interesting experiment in electric lighting has been tried at Eccles. The Electricity Committee thought it might be possible to provide electric lighting at sixpence a week for small houses. It was calculated that if, instead of every house having a separate service and meter with low-tension distributing mains, the landlords of rows of houses would instal the wirings and fittings (as some landlords do) and would also buy the electricity in bulk for the whole row, a charge of sixpence a week for each tenant would pay. The experiment was tried in a dozen cottages which were being built by the Health Committee, and has shown that the lighting yields a profit. But to make it possible the electricity must be supplied through one meter to a whole row of cottages, so that it is impossible to charge each tenant in exact proportion to what he uses. Here is perhaps the weakest point in the arrangement, but the experiment was a very interesting one, and it may be hoped that it will be tried by other electricity committees, and that builders and landlords will take note of it.

Ratner Safes.—Like most honest folk, the burglar is quick to take advantage of the discoveries of science, and his latest device is the oxy-acetylene blow-pipe, which will cut through any hitherto known form of wrought steel or iron without difficulty up to a thickness of several inches. Safe-makers have been trying for some time past to invent some means of rendering the blow-pipe inoperative in the case of bankers' and diamond merchants' safes, and strong-room doors and the Ratner Safe Company, Limited, claim to have achieved success with a special flame-resisting metal which absolutely nullifies the destructive power of the oxy-acetylene gas-flame. Messrs. Ratner's No. 7 quality patent bankers' strong-room doors are constructed with their special flame-resisting metal in the following manner:—½ in. drill-proof steel outside, ¾ in. special flame-resisting metal next, and ⅜ in. inner lock case and insertion plate, making a total thickness of 1⅝ ins. The experiments seem to have been very complete and satisfactory.

An Insurance Scheme.—Among the latest of many attempts to meet the case of persons who are anxious as to their ability to maintain the regular payment of premiums is a modification of the system of insurance by single premiums. Under this scheme an amount equal to 5 per cent. of the single premium chargeable for a given amount of insurance is paid on acceptance of the proposal, and the balance of 95 per cent. is payable in such instalments and at such periods as may be convenient to the assured. Interest on the balance of premiums remaining unpaid is charged at the rate of 4 per cent. per annum less income tax. In this way all the benefits and options attaching to a fully paid-up policy are secured to the assured from the outset, subject only to the debt represented by the amount of premium remaining due. The policies rank for the full sum assured at bonus distributions.

CORRESPONDENCE.

A PNEUMATIC RESPIRATOR.

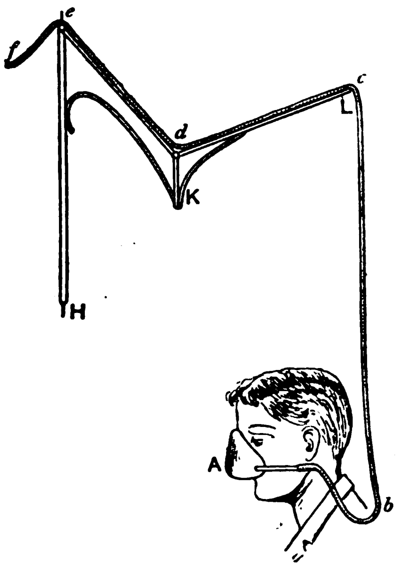
A recent visit to the granite-working factories in the city of Aberdeen has suggested to me the following arrangement for the prevention of inhalation of the dust by workmen. It is applicable to dust or fumes of all sorts, whether heavy or light.

Respirators, as is well known, are very oppressive to wear. If they are too porous, they do not arrest the dust; if they are sufficient to arrest the dust, they impede respiration to an extent that renders them almost unbearable to a man who is doing hard work, and they cause the exhaled breath to be breathed over again.

To obviate these inconveniences, I suggest the following plan:—

Let the respirator consist of a copper-shaped

vessel put over the nose and mouth, and with the edges bent so as roughly to fit the face. Around the interior edges fit some strips of fur, such as that of a rabbit or cat, sufficient to fill up the interstices between the face and the copper vessel. Into the vessel lead a small metal pipe fitting on to a rubber pipe attached to the reservoir of an air bellows. The rubber pipe is to lead up about six feet, and then be tied to a movable jointed bracket up near the ceiling of the room. By this arrangement the workman can move freely about and bend his head. The air, rushing in from the air-receptacle of the bellows, fills the copper vessel, supplies what he needs for breathing, and escapes through the rabbit skin at the sides. It is impossible for any dust to be inhaled. It will not do to work such a respirator from the air-compressors that are used in driving the pneumatic granite-



A. Copper mask.
b, c, d, e, f. India-rubber pipe.
H, K, L. Jointed bracket to carry the pipe and allow the man to move about. The bend at *b* may of course be bigger, so as to go partly down his back and up again.

dressing tools, firstly because it becomes icy cold as it expands, and secondly because it is impregnated with oil.

Nor is this needful. A bellows of wood and leather, drawing the air from some pure source, at a pressure of some 3 or 4 lbs. to the inch, is all that is needed. Inside the mask the air would, of course, have the effect of continually clearing away the exhaled breath, so that at each breath the workman would breathe fresh air, and not, as in a respirator, keep continually inhaling air already contaminated by his breath.

A rough trial in a factory has convinced me of the practicability of this method, and I desire to place it on record in the *Journal* of the Society, so that it may become public property, and free to anyone who chooses to use it.

HENRY CUNYNGHAME.

NOTES ON BOOKS.

HAND-LOOM WEAVING. By Luther Hooper. London: John Hogg. 6*s*. net.

Though the ancient craft of the hand-loom weaver is, to a large extent, obsolete in this country, it still exists in some places as a survival, in others as a revival. The substitution of mechanical for hand power, and the application of the steam engine to drive the loom at the end of the eighteenth century, rendered the old apparatus almost worthless, and ruined those who for centuries had lived by working it. Hand-weaving may have persisted as a domestic industry for a little after it had perished as a commercial one, and in the most outlying districts it has persisted to our own days. It has also been continued for the production of costly and beautiful fabrics which cannot be wrought in the machine-loom, or for which there is not sufficient demand to make their manufacture profitable on the large scale.

Perhaps it may be the revival of the art of recent years that has led to the issue of the present work; but whether this be so or not, it may certainly be commended, not only to the limited band of hand-loom workers, but to all who are interested in the textile industries.

The book (like ancient Gaul) is divided into three parts. The first deals with plain weaving, and gives a technical description of the loom and the various subordinate appliances; the second is devoted to simple pattern-weaving; and the third to complex pattern-weaving. It must be remembered that the machine-loom is not included, and there is consequently nothing beyond a mere reference to the Jacquard apparatus.

The book is throughout very fully illustrated, the illustrations in the first part including a number of pictures of various forms of old and simple weaving appliances.

JOURNALS AND REMINISCENCES OF JAMES DOUGLAS, M.D. Edited by his Son. New York: Privately printed.

It is impossible to read these interesting pages without being impressed anew by the great changes which have taken place in our life and civilisation during the last century. James Douglas was born in 1800. At the age of thirteen he was bound as an apprentice to a doctor in the Lake district. "During the second year of my time I had charge of the surgery, and made up the prescriptions. I had to visit the pauper class, as well in the country as in the town, and to report on any emergency or on the appearance of any grave symptoms . . . As perquisites, I had the shilling which was the fee for blood-letting or tooth-drawing. That for blood-letting particularly was very remunerative, as it was the custom of the country people generally to be bled every spring,

and of many, every spring and autumn. These perquisites, during three and a half years of my apprenticeship, rendered me independent of my father for the expenses of clothes and pocket-money."

On completing his apprenticeship, Douglas proceeded to Edinburgh, whence he finally graduated M.D. Before that, however, whilst still a medical student, he was offered an appointment as surgeon of a whaling ship, and at the age of eighteen he sailed for the Arctic seas. The short journal of this voyage is full of interest, telling as it does of the days before the coming of the machine-gun and the explosive harpoon, when whaling was a very perilous calling, and the boats were often smashed to pieces by the flukes of the struggling monster.

After graduating at Edinburgh and attending various lectures in London, Douglas accepted a temporary appointment at Dum Dum, near Calcutta, and he has some interesting pages on India in 1821. At that time Sutteeism was rampant. Douglas himself saw many cases of it—on one occasion witnessing two which were being conducted simultaneously—and he states that between 1804 and 1829, when the practice was declared illegal, seventy thousand widows were burnt alive in India. He also gives a lurid description of the state of the Ganges below Calcutta. So many dead bodies were flung into it that "as the ships lay off the different Ghats, the bodies frequently got across the cables, or the vessel's bows, and a dingie-wallah was stationed at each Ghat, whose sole duty it was to clear the bodies and pass them on."

Having spent a year in India, Douglas proceeded to the West Indies, where he was placed in medical charge of the Poyais settlement on the coast of Honduras. This was one of the many colonisation projects organised by promoters who took advantage of the enthusiasm excited by the struggle between Spain and her American colonies. The experiences of the unfortunate Poyais settlers were terrible. They found themselves dumped on the swampy lands at the mouth of the Black River, on a spot bearing the ill-omened name, Mosquito Shore. Here they had to contend with almost every calamity and privation that can befall the pioneer—hurricane, want of food, and sickness, which sometimes was so deadly that every person in the settlement was sick at the same time. A large percentage of the colonists died, and Douglas himself only escaped after a very severe illness.

It is not possible within the limits of these Notes to follow Douglas further in his wanderings, or to mention scores of incidents which throw a sidelight on the medical profession as it was practised half a century ago. Suffice it to say that he finally established himself in practice in Quebec, where he soon made a name as the foremost Canadian surgeon of his day. On one occasion he carried out the whole operation of amputating a leg in one minute and forty-two seconds, a speed that must have been of incalculable service to his patients in a day when anæsthetics were unknown.

The book has been excellently edited by Dr. Douglas's son, Professor James Douglas of New York, whose Cantor Lectures and papers on various mining and metallurgical subjects must be familiar to many members of the Society.

GENERAL NOTES.

The Birds'-nest Industry in Siam.—Birds'-nests form a singular item in the export trade of Siam, the shipments during the fiscal year 1909 amounting to 17,781 pounds, valued at £22,000, most of which was taken by China, Hong-Kong and Singapore. These edible nests are found in the islands off the coast of Siam, and are the products of a species of bird belonging to the family of swifts. The nests consist almost entirely of the salivary secretion of these birds, whose salivary glands are much more developed than those of the ordinary swift. The season for the gathering of the nests begins in April and ends in September. The female bird, occasionally assisted by the male, makes the nest. About three months are spent by the birds in completing their first nest, which is taken by the nest-gatherer before eggs are laid in it; then the birds immediately begin to make another nest, which is finished in about thirty days, and which is also taken. Finally, a third nest is made in about three months, in which the bird is allowed to rear its offspring, after which this nest is also gathered. Each family of birds thus furnishes three nests in one season. The nests taken at the beginning of the season are considered the best in quality. The Chinese, who consume these edible nests, regard them not only as a great table delicacy but also as a valuable tonic medicine.

Coach-building Prizes.—The Worshipful Company of Coach Makers and Coach-harness Makers of London offer the following prizes for competition among British subjects engaged in coach and coach-harness making and motor-body making, and members of drawing and technical classes in connection with such trades, resident in the United Kingdom of Great Britain and Ireland:—Competition No. 1 (open to all)—The Master, Mr. Arthur Strachan Winterbotham, offers £10 10s., and the Company £5 5s. and their silver and bronze medals, for a full-sized working drawing—side view only—of a Limousine motor carriage-body with completely enclosed front and two entrances at either side. To seat six persons, with opening glass wind-shield over dash; the drawing to show position of hind wing and wheel; designed for any known type of motor chassis of not more than 10 feet 6 inches wheel base; chassis not required; in pencil, on paper 11 feet by 7 feet. Original improvements will receive special con-

sideration. 1st prize, the Company's silver medal and £10 10s.; 2nd prize, the Company's bronze medal and £5 5s. Competition No. 2 (open to all)—For a set of four scale drawings—*i.e.*, off-side (showing levers, pedals and steering-wheel), sectional, half-rear and half-plan views—of a completely enclosed two-seated motor carriage-body (without interior upholstery); the leather hood and front screen to fold to form an entirely open carriage; the sectional drawing to be a perpendicular section taken lengthways through the middle of the body from front to back; consideration to be given to easy access on the off-side; designed for any known type of motor chassis of not more than 9 feet 6 inches wheel base; details of chassis other than specified not required; scale, 1½ inches to the foot; in ink, on paper 48 inches by 36 inches. Original improvements will receive special consideration. 1st prize, the Company's bronze medal and £5 5s.; 2nd prize, £3 3s. Competition No. 3 (open to journeyman harness-makers)—For the best single harness bridle, brass furniture, small cheek loops, black patent leather front and rosettes, for use without bearing-reins; no bit or monogram or crest on winkers required; to be the work of one man. It is suggested that harness-making firms assist by allowing competitors to effect the work where employed. 1st prize, the Company's bronze medal and £4 4s.; 2nd prize, £3 3s. Competition No. 4 (open to body-makers)—For a full-size model of portion of a carriage door fitted with a slam lock and with part of the front pillar and front cross-bar against which it shuts; to be put together with screws, so that it can be taken to pieces to inspect the joints and fitting of casing board; the whole not to exceed 16 inches long or wide. Original improvements will receive special consideration. It is suggested that carriage-making firms assist by allowing competitors to effect the work where employed. 1st prize, £4 4s.; 2nd prize, £2 2s. Competition No. 5 (open to youths under twenty-one years)—For a side view and half plan of a square landau, 5 feet 3 inches on elbow line, suitable for one horse; scale 1½ inches to the foot; in pencil, on paper 27 inches by 18 inches. 1st prize, £3 3s.; 2nd prize, £2 2s.; 3rd prize, £1 1s. Each of the prizes will be accompanied by the certificate of the Company.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock :—

November 30.—Campbell P. Ogilvie, "Argentina from a British Point of View." Sir Alexander Henderson, Bart., will preside.

December 7.—Vaughan Cornish, D.Sc., F.G.S., F.C.S., "The Panama Canal in 1910." Sir William H. White, K.C.B., F.R.S., will preside.

December 14. — Reginald A. Smith, B.A., F.S.A., "A New View of Roman London."

Colonial Section.

Tuesday afternoon, at 4.30 o'clock :—

November 29.—A. Montgomery, M.A., F.G.S., "The Progress and Prospects of Mining in Western Australia." Admiral Sir Frederick George Denham Bedford, G.C.B., will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock :—

December 15.—Robert Fellowes Chisholm, F.R.I.B.A., F.S.A., "The Taj Mahal and its Relation to Indian Architecture."

Cantor Lectures.

Monday Evenings, at 8 o'clock :—

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Industrial Pyrometry." Four Lectures.

Lecture II.—November 28.—Laws of thermo-electricity — Thermo-electric pyrometers of Le Chatelier and Roberts-Austen—Temperature indicators—Recorders, ink and photographic—Arrangement of a number of pyrometers centrally controlled —Determination of the critical points of steel—Application to hardening and tempering—Limits of use.

Lecture III.—December 5.—Laws of resistance to electricity—Siemens' resistance pyrometer—Callendar's pyrometer — Principles of resistance measurement—Temperature indicators for resistance pyrometer—Callendar's recorder—Northrup's recorder—Special uses and limitations of resistance pyrometers.

Lecture IV.—December 12.—Radiant energy—The "fourth-power" law—Laws of Wein and Planck—The Féry radiation pyrometers and indicators—The Holborn-Kurlbaum optical pyrometer —Wanner's pyrometer—Other optical pyrometers —Special uses of radiation pyrometers in pottery manufacture and work at very high temperatures.

Papers to be read after Christmas :—

Horace M. Wyatt, "Motor Transport in Great Britain and the Colonies."

Philip Joseph Hartog, M.A., B.Sc., "Examinations and their bearing on National Efficiency."

J. C. Medd, "The Dutch Labour Colonies."

Cyril Davenport, "Illuminated Manuscripts."

George A. Stephen, "Modern Machine Bookbinding."

Professor J. Wertheimer, B.Sc., B.A., "Water-Finders."

Captain A. J. N. Tremearne, "Some Nigerian Head-Hunters."

Hon. Sir Richard Solomon, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the

Union of South Africa, "South Africa before and after the Union."

F. DOUGLAS OSBORNE, M.Inst.M.M., "The Tin Resources of the Empire."

REGINALD MURRAY, "Indian Banking."

R. A. LESLIE MOORE, I.C.S. (retd.), "Indian Superstitions."

Captain R. MUIRHEAD COLLINS, C.M.G., "Australia and her Resources."

FRANK M. ANDREWS, "Architecture in America."

ARTHUR CHARLES DAVIS, F.C.S., Assoc.Inst.C.E., "The Manufacture and Testing of Portland Cement."

GEORGE B. HEMING, "Art Education in Jewellery and Goldsmithing."

Colonel CHARLES EDWARD CASSAL, V.D., F.I.C., "The Adulteration of Food."

Dr. LEONARD HILL, F.R.S., "Caisson Sickness and Compressed Air."

Sir WILLIAM ABNEY, K.C.B., D.C.L.. D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

HAL WILLIAMS, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

January 19, February 9, March 16, April 27, May 25.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

January 31, February 28, April 4, May 9.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

FREDERICK WEDMORE, "Etching": 1. "The Old Masters;" 2. "Modern Etching." Two Lectures.

January 23, 30.

Professor ADRIAN J. BROWN, M.Sc., "Brewing." Four Lectures.

February 6, 13, 20, 27.

Professor J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

March 6, 13, 20, 27.

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

JUVENILE LECTURES.

Wednesday evenings, January 4 and 11, 1911, at 5 o'clock:—

Professor ARTHUR MASON WORTHINGTON, C.B., M.A., F.R.S., "A Study of Splashes, conducted by the aid of Instantaneous Photography." Two Lectures.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 28...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. C. R. Darling, "Industrial Pyrometry." (Lecture II.)

Surveyors, 12, Great George-street, S.W., 8 p.m.

Actuaries, Staple Inn Hall, Holborn, W.C., 5 p.m. Inaugural Address by the President, Mr. G. H. Ryan.

London Institution, Finsbury-circus, E.C., 5 p.m. Major Ronald Ross, "Malaria."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. A. Oliver, "Notes on Some French Churches."

TUESDAY, NOVEMBER 29...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. A. Montgomery, "The Progress and Prospects of Mining in Western Australia."

Sociological (at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8 p.m. Professor Michael Sadler, "The State and Education."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Bamber's Paper, "Portland Cement, and the Question of its Aeration."

Photographic, 35, Russell-square, W.C., 8 p.m. Discussion on "Time Development," by Dr. Mees, Mr. W. B. Ferguson, and Mr. Alfred Watkins.

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Mr. J. Ferguson, "Ceylon, the Malay States, and Java, Compared as Plantation and Residential Colonies."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Dr. H. B. Fantham and Mr. H. Hammond Smith, "On a Possible Cause of Pneumo-enteritis in the Red Grouse (*Lagopus scoticus*)." 2. Mr. F. E. Beddard, "On the Alimentary Tract of certain Birds, and on the Mesenteric Relations of the Intestinal Loops." 3. Professor A. Cabrera, "On the Specimens of Spotted Hyenas in the British Museum (Natural History)." 4. Dr. J. F. Gemmill, "The Development of *Solaster endeca* Forbes."

WEDNESDAY, NOVEMBER 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Campbell P. Ogilvie, "Argentina from a British Point of View."

Cold Storage and Ice Association, Merchants' Hall, Baltic Exchange, St. Mary Axe, E.C., 8 p.m. Mr. C. T. Brightman, "Refrigerated Cargoes and their Insurance."

British Astronomical, Sion College, Victoria Embankment, E.C., 5 p.m.

THURSDAY, DECEMBER 1....Linnean, Burlington House, W., 8 p.m. 1. Captain C. F. U. Meek, "Spermatogenesis in Stenobothrus." 2. Dr. Otto Stapf and others, "Reports on the International Botanical Congress at Brussels, 1910."

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. M. O. Forster and S. H. Newman, "The Triazo-group. Part XV. Triazoethylene (vinylazoimide) and the Triazoethyl Halides." 2. Mr. W. J. Jones, "The Determination of Solubility coefficients by Aspiration." Preliminary note. 3. Messrs. F. D. Chattaway and M. Aldridge, "The Auto-reduction of Hydrazines." 4. Messrs. G. T. Morgan and A. Clayton, "The Nitro-Derivatives of Dimethyl-p-toluidine."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. E. W. D. Manson, "Imprisonment for Debt."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. Francis Ward, "Phases of Fish Life and How to Record Them."

Roentgen Society, 19, Hanover-square, W., 8.15 p.m.

FRIDAY, DECEMBER 2...British Academy, in the Theatre, Burlington-gardens, W., 5 p.m. The Very Rev. George Adam Smith, "The Early Poetry of Israel in its Physical and Social Origins."

African Society, Trocadero Restaurant, Shaftesbury-avenue, W., 8 p.m. Sir George T. Goldie, "The African Society."

Journal of the Royal Society of Arts.

No. 3,028. VOL. LIX.

FRIDAY, DECEMBER 2, 1910.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 5th, 8 p.m. (Cantor Lecture.) CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Industrial Pyrometry." (Lecture III.)

WEDNESDAY, DECEMBER 7th, 8 p.m. (Ordinary Meeting.) VAUGHAN CORNISH, D.Sc., F.G.S., F.C.S., "The Panama Canal in 1910." Sir WILLIAM H. WHITE, K.C.B., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, November 28th, Mr. CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., delivered the second lecture of his course on "Industrial Pyrometry."

The lectures will be published in the *Journal* during the Christmas recess.

COLONIAL SECTION.

Tuesday afternoon, November 29th; Admiral Sir FREDERICK GEORGE DENHAM BEDFORD, G.C.B., late Governor of Western Australia, in the chair. A paper on "The Progress and Prospects of Mining in Western Australia" was read by A. MONTGOMERY, M.A., F.G.S., State Mining Engineer to the Government of Western Australia.

The paper and discussion will be published in a subsequent number of the *Journal*.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 4th and 11th, at 5 o'clock, by ARTHUR MASON WORTHINGTON, C.B., M.A., F.R.S., Professor of Physics in the Royal Naval Engineering College, Devonport, on "A Study of Splashes, conducted by the aid of Instantaneous Photography."

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Members who desire tickets for the course are requested to apply for them at once.

ROYAL SOCIETY OF ARTS ALBERT MEDAL.

At the request of the Council, Sir Edward Grey, Secretary of State for Foreign Affairs, authorised the transmission of the Society's Albert Medal to His Majesty's Ambassador at Paris for presentation to Madame Curie. Sir Francis Bertie received Madame Curie at the British Embassy on November 25th, and handed to her the Albert Medal, stating that he had been instructed by the Secretary of State to present it to her on the part of the Royal Society of Arts in recognition of the services rendered to the world by her discovery of Radium, and adding that it gave him great pleasure to be the medium of carrying out the wishes of the Society.

PROCEEDINGS OF THE SOCIETY.

THIRD ORDINARY MEETING.

Wednesday, November 30th, 1910; Sir ALEXANDER HENDERSON, Bart., in the chair.

The following candidates were proposed for election as members of the Society:—

Briggs, Miss Irlam, Milnthorpe, Parkstone, Dorset.
Cooper, Alfred Heaton, May Field, Ulverstone, Lancashire.

McDonald, Thomas J., Assoc.M.Inst.C.E., Mansfield, Arrochar, Loch Long, N.B.

Mitchell, Hawthorn, 39, Mecklenburgh-square, W.C.

Murray, Reginald, 12, Bedford-row, W.C.

Power, John Cecil, 1, Queen's-ride, Barnes Common, S.W.

Sotham, Bernard, c/o Messrs. Lynch, Teheran, Persia, and The Priory, Iffley, Oxford.

Stanley, William Neems, 12, Spencer-road, Cottenham Park, Wimbledon, Surrey.

Wheeler, R. Vernon, D.Sc., The Colliery House, Altofts, Yorkshire.

The following candidates were balloted for and duly elected members of the Society :—

Aitken, William, 17, Church-street, Dumbarton, N.B.

Anderson, Rev. James Forrester, B.D., B.Sc., B.A., St. John's Presbyterian Church, Port Louis, Mauritius.

Anderson, Robert, 8, Esplanade East, Calcutta, India.

Andrews, Frank M., Metropolitan Building, New York City, U.S.A.

Archibald, Captain James F. J., 1053, Marbridge Building, Herald-square, New York City, and Army and Navy Club, Washington, D.C., U.S.A.

Arnold, Felix, Ph.D., A.B., 824, St. Nicholas-avenue, New York City, U.S.A.

Arnot, David, c/o Messrs. Wilson, Sons & Co., Rio de Janeiro, Brazil.

Barrow, John, 26, Old Broad-street, E.C.

Bethune, J. T., 406, Eastern Townships Bank Building, Montreal, Canada.

Biswas, Jatindra Kumar, M.A., 23, Crematorium-street, Entally, Calcutta, India.

Blair, David Ker, M.I.Mech.E., 11, Grey-street, Wellington, New Zealand.

Blamires, Joseph, Bradley Lodge, Huddersfield.

Brown, Percy, 28, Chowringhee, Calcutta, India.

Burlton, C. H. B., Highmore-house, Hereford.

Chessum, Roland B., Woodbury, Enfield, N., and 7A, South-place, E.C.

Clifford, Charles, Chudleigh, Halfin-road, Rangoon, Burma.

Clutton, Miss Maria, 5, Chester-place, Regent's-park, N.W.

Davidson, David, Station-house, Galashiels, Scotland.

Day, Miss Ruth M., 15, Taviton-street, W.C.

Deb, Atindra Krishna, 4, Shampuker-lane, Calcutta, India.

Dickinson, H. P., 807, Majestic Building, Denver, Colorado, U.S.A.

Duncan, Professor Robert Kennedy, 4715, Wallingford-street, Pittsburgh, Pennsylvania, U.S.A.

Dunnington, Professor Francis P., University of Virginia, Charlotteville, Virginia, U.S.A.

Fauth, J., Messrs. Zaretzky, Bock and Co.'s Rice Mills, Dawbong, Rangoon, Burma.

Ferguson, James R., Rooms 314-315, Birk's Building, Montreal, Canada.

Fripp, R. MacKay, 429, Pender-street West, Vancouver, British Columbia, Canada.

Gage, Professor Simon Henry, Stimson-hall, Cornell University, Ithaca, New York, U.S.A.

Gajjar, Professor T. K., M.A., B.Sc., F.C.S., Techno-Chemical Laboratory, near Girgaum, Tram Terminus, Bombay, India.

Ganguly, Ananda Lal, Khalia P.O., Faridpur District, East Bengal, India.

Garnham, James Coote, 132, Upper Thames-street, E.C., and Holmleigh, 3, Fountayne-road, Stoke Newington, N.

Garrett, Thomas Richard Henry, M.A., c/o Messrs. G. Gillespie and Co., Rangoon, Burma, and 16, Queensland-road, Boscombe, Hants.

Giangirji, Raja Bahadur Narsingirji, Begum Bazaar, Hyderabad, Deccan, India.

Gilbert-Wood, Clarence, 5 and 3, Arundel-street, Strand, W.C., and Bertwood, Wimbledon, S.W.

Gill, George T. S., 37, Lancaster-road, Hampstead, N.W.

Greenwell, George Harold, c/o Messrs. Kilburn, and Co., 4, Fairlie-place, Calcutta, India.

Gregg, William Henry, M.D., 135, Cambridge-place, Brooklyn, New York, U.S.A.

Hazard, Hon. Rowland Gibson, A.M., Holly-house, Peace Dale, Rhode Island, U.S.A.

Hollingsworth, John Burton Lee, D.V.S., M.D.C., 105, Cambridge-street, Ottawa, Canada.

Horne, Rev. Joseph White, M.A., Ivy-house, High-street, Highgate, N.

Hotson, John Ernest Buttery, I.C.S., Secretariat, Bombay, India.

Huber, E. H., 510, Quincy Building, Denver, Colorado, U.S.A.

Innes, Charles, B.Sc., Assoc.M.Inst.C.E., c/o Messrs. T. Cook and Sons, Rangoon, Burma.

Jacobs, J. Warren, Waynesburg, Pennsylvania, U.S.A.

Katayama, Tokuma, Bureau of Works of the Imperial Household Department, Tokio, Japan.

Keay, Lyle, The Mercantile Bank of India, Calcutta, India.

Knight, Joseph, Southfields, Bury, Lancashire.

Lay, Harry Arthur, 45, Hanley-road, Hornsey-rise, N.

Lee, Professor Edwin, B.S., A.M., M.Sc., Meadville, Penn., U.S.A.

Leggatt, Percy Scott, 15, Marine-parade, Lowestoft.

Levene, Dr. P. A., 230, West 139th Street, New York City, U.S.A.

Lubbock, Hon. John Birkbeck, 15, Lombard-street, E.C.

McBride, James H., M.D., Pasadena, California, U.S.A.

Mead, Marvin Hulst, 382, River-drive, Passaic, New Jersey, U.S.A.

Mitchell, Francis James, Srinagar, Kashmir State, India.

Morris, William Hardwicke Grant, A.M.I.Mech.E., Cairo Water Works, Rod El Farig, Egypt.

Mower, Charles Huson, 147, Queen Victoria-street, E.C., and 14, Lower Berkeley-street, W.

Muthukoya-Thangal, Khan Bahadur P.M., Calicut, India.

Nath, Rai Sahib Dewan Amar, Chief Minister to His Highness the Maharaja, Jammu and Kashmir State, India.

Nichalls, J. Mayne, The Nitrate Railways Co., Ltd., Iquique, Chili, South America.

O'Callaghan, T. P. M., Gauhati, Assam, India.

Peart, Arthur Wellesley, B.A., The Maples, Burlington, Ontario, Canada.

Percy, Norman Crook, Assoc.M.Inst.C.E., Byculla Ironworks, Bombay, India.

Pitt, George Earley, B. ès L., Knutsford, Cadbury-road, Moseley, Worcester.

Poats, Thomas Grayson, Clemson Agricultural College, Clemson College, South Carolina, U.S.A.

Powell, Henry Richard, South Lawn, Bickley, Kent.

Prentice, Thomas Theophilus, Assoc.M.Inst.C.E., Empresa del Agua, Lima, Peru, South America.

Pyne, Herbert Barrington, Assoc.M.Inst.C.E., 370, Calle Cangallo, Buenos Aires, Argentine.

Richards, H. W., Brookside, Beverley-road, Barnes, S.W.

Robinson, James, Assoc.M.Inst.C.E., Bhagalpur, Bengal, India.

Roe, Richard Dartnell Tennant, Assoc.M.Inst.C.E., Sir John Jackson (Chile), Ltd., Ferro Carril Arica La Paz, Arica, Chile, South America.

Rohrer, C. W. G., M.A., M.D., B.Sc., Baltimore, Maryland, U.S.A.

Sahasrabudhe, Rao Sahib Ganesh Nagesh, Ellichpur, Amraoti District, Berar, Central Provinces, India.

Seligmann, Albert, 49, Fitzjohn's-avenue, N.W.

Sharrock, Charles Williams, Dorincourt, Grays, Essex.

Sheoparshad, Rai Bahadur Lala, Rais and Honorary Magistrate, Chandni Chowk, Delhi, India.

Shukul, Rai Bahadur Pundit Bishun Dutta, Sehora-road (E.I. Railway), Jubbulpore District, Central Provinces, India.

Smeaton, Major Charles Oswald, R.A., United Service Club, Pall Mall, S.W.

Smith, William Charles Ernest, M.Inst.C.E., The Nitrate Railways Co., Iquique, Chile, South America.

Spoor, Stanley M., 59, Chancery Lane, W.C.

Stewart, Captain Thomas, V.D., K.I.H., 1, Thackeray-road, Alipore, Calcutta, India.

Stirk-Inglis, F. A., c/o O. H. McCowan, LL.B., Y.M.C.A., Rangoon, Burma.

Stowell, Herbert, 10, Morley-road, Southport.

Taylor, Edward, 17, Thurleigh-road, Wandsworth-common, S.W.

Watkins, Stephen, Assoc.M.Inst.C.E., Ottoman Railway, Smyrna, Turkey in Asia.

Wills, J. Lainson, F.C.S., 133, Midwood-street, Brooklyn, New York, U.S.A.

Woodhouse, Thomas, Briarcliffe, Wormit, near Dundee.

Yearsley, Walter A., Rosador, St. Anne's-on-Sea, Lancashire.

Zizold, Alfredo, Lima, Peru, South America.

The paper read was—

ARGENTINA FROM A BRITISH POINT OF VIEW.

By Campbell P. Ogilvie.

Argentina, which does not profess to be a manufacturing country, exported in 1909 material grown on her own lands to the value of £79,000,000, and imported goods to the extent of £60,000,000. This fact arrests our attention, and forces us to recognise that there is a trade balance of nearly 20 million pounds sterling in her favour, and to realise the saving power of the country.

It is not mere curiosity which prompts us to ask: "Are these £79,000,000 worth of exports of any value to us? Do we consume any of them? Do we manufacture any of them? And do we send any of this same stuff back again after it has been dealt with by our British artisans?" It would be difficult to follow definitely any one article, but upon broad lines the questions are simple and can be easily answered. Amongst the agricultural exports we find wheat, oats, maize, linseed, and flour. The value placed upon these in 1908 amounted to £48,000,000, and England pays for and consumes nearly 42 per cent. of these exports. Other goods, such as frozen beef, chilled beef, mutton, pork, wool, and articles which may be justly grouped as the results of the cattle and sheep industry, amounted to no less a figure than £23,000,000. All these exports represent foodstuffs or other necessities of life, and are consumed by those nations which do not produce enough from their own soil to keep their teeming populations. Another export which is worthy of particular mention comes from the forests, viz., quebracho, which, in the form of logs and extract, was exported in 1908 to the value of £1,200,000. The value of material of all sorts sent from England to Argentina in 1908 was £16,938,872 (this figure includes such things as manufactured woollen goods, leather goods, oils, and paints), therefore it is clear that we have, and must continue to take, a practical and financial

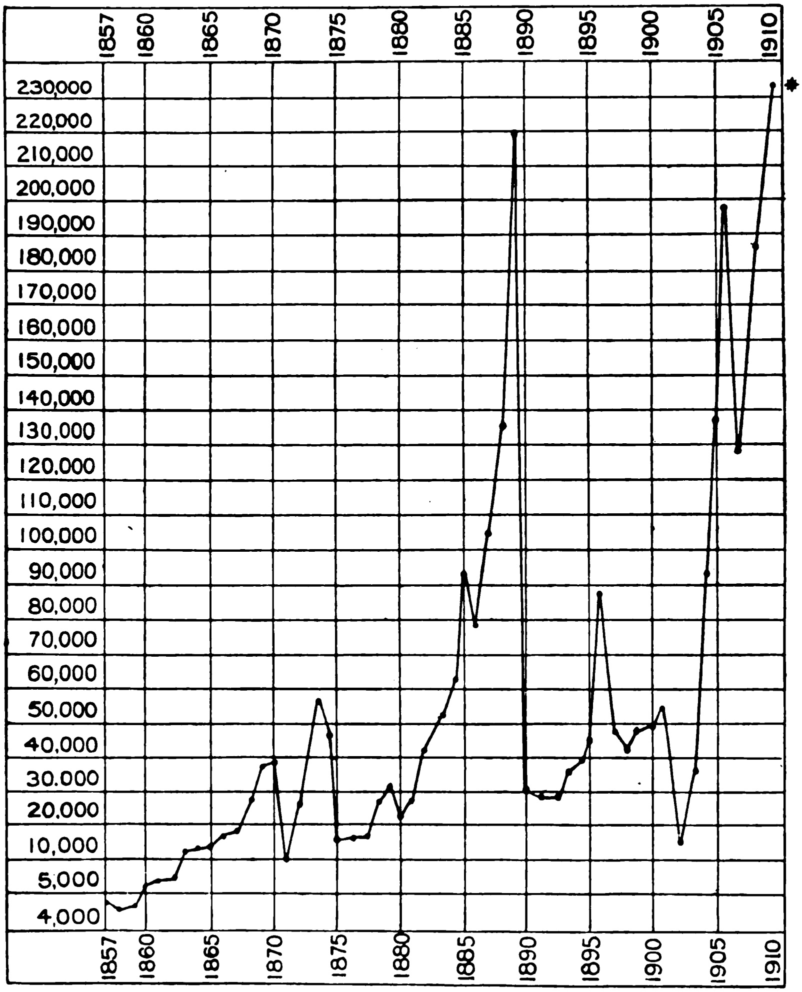
interest in the welfare and prosperity of Argentina.

New countries cannot get on without men willing and ready to exploit Nature's gifts, and, naturally, we look to the immigration returns when considering Argentina's progress. To give each year's return for the last fifty years would be wearisome, but, taking the average figures for ten-year periods from 1860 to 1909, we have the following interesting table (the figures represent the balance of those left in the country after allowing for emigration):—

	Yearly average.
From 1860 to 1869 (inclusive) . .	15,044
„ 1870 „ 1879 „ . .	29,462
„ 1880 „ 1889 „ . .	84,586
„ 1890 „ 1899 „ . .	43,618
„ 1900 „ 1909 „ . .	100,998

TABLE I.

DIAGRAM OF IMMIGRATION RETURNS.



* 231084 IN 1909

NOTE:— IN THE YEARS 1888, 1889 & 1890 THE ARGENTINE GOVERNMENT ASSISTED PASSAGES.

Sixty-five per cent. of the immigrants are agricultural labourers, who soon find work in the country, and again add their quota to the increasing quantity and value of materials to be exported.

Table I. is a diagram of the Immigration Returns from 1857 to 1909.

Nature has been lavish in her gifts to Argentina, and man has taken great advantage of these gifts. My desire now is to show what has been done in the way of developing agriculture in this richly-endowed country during the last fifty years. One name which should never be forgotten in Argentina is that of William Wheelwright, whose entrance into active life in Buenos Aires was not particularly dignified. In 1826 he was shipwrecked at the mouth of the River Plate, and struggled on barefooted, hatless and starving, to the small town of Quilmes.

Mr. Wheelwright was an earnest and far-seeing man, and his knowledge of railways in the United States helped him to realise their great possibilities in Argentina; but, strange to say, upon his return to his native land he could not impress any of those men who afterwards became such great "Railway Kings" in the U.S.A. Failing to obtain capital for Argentine railway development in his own country, Wheelwright came to England, and interested Thomas Brassey, whose name was then a household word amongst railway pioneers. These two men associated themselves with Messrs. Ogilvie and Wythes, forming themselves into the firm of Brassey, Ogilvie, Wythes and Wheelwright, whose first work was the building of a railway 17·480 kilometres long between Buenos Aires and Quilmes in 1863; afterwards they built the line from Rosario to Cordova, which is embodied to-day in the Central Argentine Railway. Other railways were projected, and this policy of progress and extension of the steel road still holds good in Argentina.

The year 1857 saw the first railway built, from Buenos Aires to Flores, 5·879 kilometres long; in 1870 there were 457 miles of railroad; in 1880 the railways had increased their mileage to 1,572; in 1890 Argentina possessed 5,895 miles of railway, and in 1900 there were 10,352 miles.

The rapid increase in railway mileage during the last nine years is as follows:—

In 1901	there	were	10,565	miles	of	railway.
„ 1902	„	„	10,868	„	„	„
„ 1903	„	„	11,500	„	„	„
„ 1904	„	„	12,140	„	„	„
„ 1905	„	„	12,370	„	„	„
„ 1906	„	„	12,850	„	„	„
„ 1907	„	„	13,829	„	„	„
„ 1908	„	„	14,825	„	„	„
„ 1909	„	„	15,937*	„	„	„

* These figures are approximate.

12,000 of these are owned by English companies, representing a capital investment of £170,000,000.

In other words, for the last forty years Argentina has built railways at the rate of over a mile a day, and in 1907, 1908, and 1909 her average rate per day was nearly three miles. This means that, owing to the extension of railways during this last year alone, over a million more acres of land could have been given up to the plough if suitable for the cultivation of corn.

When William Wheelwright first visited Argentina it was little more than an unknown land, whose inhabitants had no ambition, and no desire to acquire wealth—except at the expense of broken heads. There was a standard of wealth, but it lay in the number of cattle owned; land was of little value, save for feeding cattle, and therefore counted for naught, but cattle could be boiled down for tallow; bones and hides were also marketable commodities; the man, therefore, who possessed cattle possessed wealth.

The opening out of the country by railways soon changed the aspect of affairs. The man who possessed cattle was no longer considered the rich man; it was he who owned leagues of land upon which wheat could be grown who became the potentially rich man; he, by cutting up his land and renting it to the immigrants, who were beginning to flock in an endless stream into the country, found that riches were being accumulated for him without much exertion on his part. He took a risk, inasmuch as he received payment in kind only. Therefore, when the immigrants did well, so did he, and, as many thousands of immigrants have become rich, it follows that the land proprietors have become immensely so. It was the railways which created this possibility, and endowed the country by rendering it practicable to grow corn where cattle only existed before, but many Argentines to-day forget what they owe to the railway pioneers; it is the railways, and the railways only, which render the splendid and yearly increasing exports possible.

In 1858 cattle formed 25 per cent. of the total wealth of Argentina, but in 1885 cattle only represented 18 per cent. of the total wealth, railways having made it possible during those thirty years to utilise lands for other purposes than cattle-feeding. Let it be clearly understood, the total value of cattle had not decreased; far from that, the cattle had increased in value during the above period to the extent of

£48,000,000, and to-day cattle, sheep, horses, mules, pigs, goats, and asses represent a value of nearly £130,000,000. The following table shows how great the improvement has been in Argentine animals:—

			Per head.
Cattle in	1885	were valued at an average of	$13*
„	1908	„ „ „	$32
Sheep in	1885	„ „ „	$ 2
„	1908	„ „ „	$ 4
Horses in	1885	„ „ „	$11
„	1908	„ „ „	$25

Notwithstanding these increased valuations per head, and the larger number of animals in the country, the value created by man's labour far outweighs the increased value of mere breeding animals.

Next to the railways the improvements in shipping have helped the development of Argentina; the shipping trade of Buenos Aires has increased at the rate of one million tons per annum for the past few years, and the entries into the port form an interesting and instructive table.

The following statement gives the total tonnage that passed through the port of Buenos Aires from 1880 to 1909, and will more clearly show the increase and advance made in the last thirty years. These figures include both steamers and sailing-vessels, and local as well as foreign trade:—

	Tons.		Tons.
1880 ..	644,750	1895 ..	6,894,834
1881 ..	827,072	1896 ..	6,115,547
1882 ..	995,597	1897 ..	7,365,405
1883 ..	1,207,321	1898 ..	8,051,045
1884 ..	1,782,382	1899 ..	8,741,934
1885 ..	2,200,779	1900 ..	8,047,010
1886 ..	2,408,323	1901 ..	8,661,300
1887 ..	3,369,057	1902 ..	8,902,605
1888 ..	3,396,212	1903 ..	10,269,298
1889 ..	3,804,037	1904 ..	10,424,615
1890 ..	4,507,096	1905 ..	11,467,954
1891 ..	4,546,729	1906 ..	12,448,219
1892 ..	5,475,942	1907 ..	13,335,733
1893 ..	6,177,818	1908 ..	15,465,417
1894 ..	6,686,123	1909 ..	16,993,973

In 1897, out of the total number of steamers that entered Buenos Aires—viz., 901, with a tonnage of 2,342,391—519, with a tonnage of 1,327,571, were British. Taking the year 1909 we find that 2,008 steamers and 137 sailing-vessels entered the port of Buenos Aires from foreign shores with a tonnage of 5,193,542, and 1,978 steamers and 129 sailing-vessels left the port for foreign shores with a tonnage of 5,174,114; out of these, British boats lead with 2,242 steamers and 37 sailing-vessels, or, say, 53½ per cent. of the total. Germany comes next with 456 steamers and two sailing-vessels, or, say, 10¾ per cent. of the total. Italy, with 307 steamers and 67 sailing-vessels, is next, and then France with 264 steamers. The total number of steamers that entered and left the port from local and foreign ports is 13,485, with a tonnage of 14,481,526, and 20,264 sailing-vessels with 2,512,447 tons, which make up the amount of 16,993,973 tons, as shown above.

In the year 1884 the experiment of freezing beef killed in Buenos Aires, and shipping it to Europe was first tried. That was successful, but an immense improvement was made when the process of chilling became the common means by which meat could be exported. The frozen beef trade in Argentina has had a wonderful development; it commenced in 1884, and the export of chilled meat has progressed steadily at the rate of 25,000 beeves yearly, until, in 1908, it reached the enormous quantity of 573,946 beeves, or 180,000 tons. Frozen mutton has remained comparatively steady, and has only increased by 38,000 tons in twenty-two years, or from 2,000,000 sheep frozen in 1886 to 3,297,667 in 1908, whilst "jerked beef," which was mostly sent to Cuba and Brazil, has fallen from 50,000 tons per annum to 6,651 tons. The value of frozen and preserved meats exported in 1908 was £5,233,948.

The value of live-stock in Argentina in 1908 was made up as follows:—

Cattle	£82,000,000
Sheep	25,000,000
Horses	18,000,000
Mules	2,000,000
Pigs	1,368,000
Goats and Asses	1,000,000

A few years ago it was common on an estancia feeding 50,000 or 60,000 cattle to find the household using canned Swiss milk. To-day, 425,000 litres of milk are brought into the city of Buenos Aires each day for consumption, and no less than two tons of butter, one ton of cream, and three tons of cheese are used there daily. Argentina also exports butter. This trade has sprung up entirely within the last fourteen years, and in 1908 she exported 3,549 tons of butter, the value of which was £283,973.

* The dollar referred to throughout this Paper is the Argentine paper dollar which since 1899 has had a fixed value, and is worth approximately 1s. 9d. Previous to that date its value fluctuated considerably.

Until 1876 Argentina imported wheat for home consumption; in that year, when for many years past agricultural labourers had been arriving at an average of 25,000 per annum, she began to export wheat with a modest shipment of 5,000 tons. Thirty years later the export had mounted up to 2,247,988 tons, and in 1908 the wheat exported amounted to 3,636,293 tons, and was valued at £25,768,520. Agricultural colonies had sprung up everywhere, and cattle became of second-rate importance; to-day the value of the exports of corn, which term includes wheat, barley, maize, oats, etc., is more than double that of cattle and cattle products. It is interesting to follow the evolution wrought by labour, intelligence, and capital in the prairie lands of Argentina. First, let us note the developments on those wonderful tracts of splendid prairie lands lying between the River Plate and the Andes; fifty years ago these lands were of little account, and only a few cattle were to be found roaming about them, but upon the advance of the railway they came under the plough, and, without much attention or care, produced wheat and maize. After a time improvements in the method of cultivation produced a better return, and to-day a great deal of attention is paid to the preparing of the land, and thought and care are given to the seed-time, the growing and the harvest. When it is found desirable to rest the land after crops of wheat and maize, etc., alfalfa is grown thereon. Alfalfa is one of the clover tribe, and has the peculiar property of attaching to itself those micro-organisms which are able to fix the nitrogen in the air and render it available for plant food. Every colonist knows the value of alfalfa for feeding his animals, but it is not every colonist who knows why this plant occupies such a high place amongst feeding-stuffs. Alfalfa is easily grown, very strong when established, and, provided its roots can get to water, will go on growing for years. The *raison d'être* for growing alfalfa is for the feeding of cattle and preparing them for market, and for this purpose a league of alfalfa (6,177 acres metric measurement) will carry on an average 3,500 head. When grown for dry fodder it produces three or four crops per annum and a fair yield is from six to eight tons per acre of dry alfalfa for each year. A ton of such hay is worth about $20 to $30, and after deducting expenses there is a clear return of about $14 per acre.

The figures supplied by one large company are interesting; they show that on an average, cattle, when placed upon alfalfa lands, improve in value at the rate of $2.00 per head per month so it is easy to place a value on its feeding properties. Thus we will take a camp under alfalfa capable of carrying 10,000 head of cattle all the year round, where, as the fattened animals are sold off, an equal number is bought to replace them. Such a camp would bring in a clean profit of $200,000 per annum, and the property should be worth £175,000 sterling. An animal that has been kept all its life on rough camp, and, when too old for breeding, is placed for the first time on alfalfa lands, fattens extremely quickly, and the meat is tender and in quality compares favourably with any other beef. No business in Argentina of the same importance has shown such good returns as cattle breeding, and these results have been chiefly brought about by the introduction of alfala, fand a knowledge of the life history of alfalfa is of the greatest importance to the cattle farmer. All cereal crops take from the soil mineral matter and nitrogen. Therefore, after continuous cropping, the land becomes exhausted and generally poorer; experience has taught us that rotation of crops is a necessity to alleviate the strain on the soil, and such an axiom has this become that in many cases English landlords insist that their leases shall contain a clause binding the tenants to grow certain stated crops in rotation.

This system is known in England as the four-course shift. Knowledge gained by successive generations of observant farmers has given us the key to what Nature had hitherto kept to herself, and to-day we know why the plan adopted by our forefathers was right, and why the rotation of crops was, and is, a necessity. Men of science are devoting their lives to the systematic study of Nature's hidden secrets, and by means of agricultural colleges, as well as private individual research, these discoveries are being given to mankind, and long before the soils of Argentina show any serious loss of nitrogen from continuous cropping, science will probably have established means of applying in a practical manner those methods already known of propagating the nitrogen-collecting bacteria which thrive on alfalfa, clover, peas, soya beans, and other leguminous plants. Almost every country is now devoting time, money, and energy to agricultural research work. In 1908 the Agricultural College at Ontario prepared no less than 474 packages of legume bacteria, and in 309 cases beneficial results followed from the application thereof to the soil; in 165 cases no improvements in the crops were noticed. This may, however, have been due to the want of

knowledge of how to manipulate the bacteria, or to lack of experience in noting effects scientifically, but in any case the experiment must be considered successful when the results obtained were satisfactory in no less than 65 per cent. of the trials. No greater factor exists than the microscope in opening up and hunting out the secrets concealed in the very soil we are standing on.

If soils were composed of nothing but pure silica sand, nothing would ever grow; but in Nature we find that soils contain all sorts of mineral matter, and chief amongst these is lime.

Alfalfa thrives on land which contains lime, and gives but poor results where this ingredient is deficient. The explanation is simple. There is a community of interest between the very low microscopic animal life, known as bacteria, and plant life generally. In every ounce of soil there are millions of these living germs which have their allotted work to do, and they thrive best in soils containing lime.

If one digs up with great care a root of alfalfa (it need not be an old plant, the youngest plant will show the same peculiarity), and care is taken in exposing the root (perhaps the best method is the washing away of the surrounding earth by water), some small nodules attached to the fine, hair-like roots are easily distinguished by the naked eye, and these nodules are the home of a teeming, microscopical, industrious population, who perform their allotted work with the silent, persistent energy so often displayed in Nature. Men of science have been able to identify at least three classes of these bacteria, and to ascertain the work accomplished by each. The reason for their existence would seem to be that one class is able to convert the nitrogen in the air into ammonia, whilst others work it into nitrite, and the third class so manipulate it as to form a nitrate which is capable of being used for plant food.

Now, although one ton of alfalfa removes from the soil 50 lbs. of nitrogen, yet that crop leaves the soil richer in nitrogen, because the alfalfa has encouraged the multiplication of those factories which convert some of the thousands of tons of nitrogen floating above the earth into substance suitable for food for plant life. As a dry fodder for cattle three tons of alfalfa contain as much nutrition as two tons of wheat.

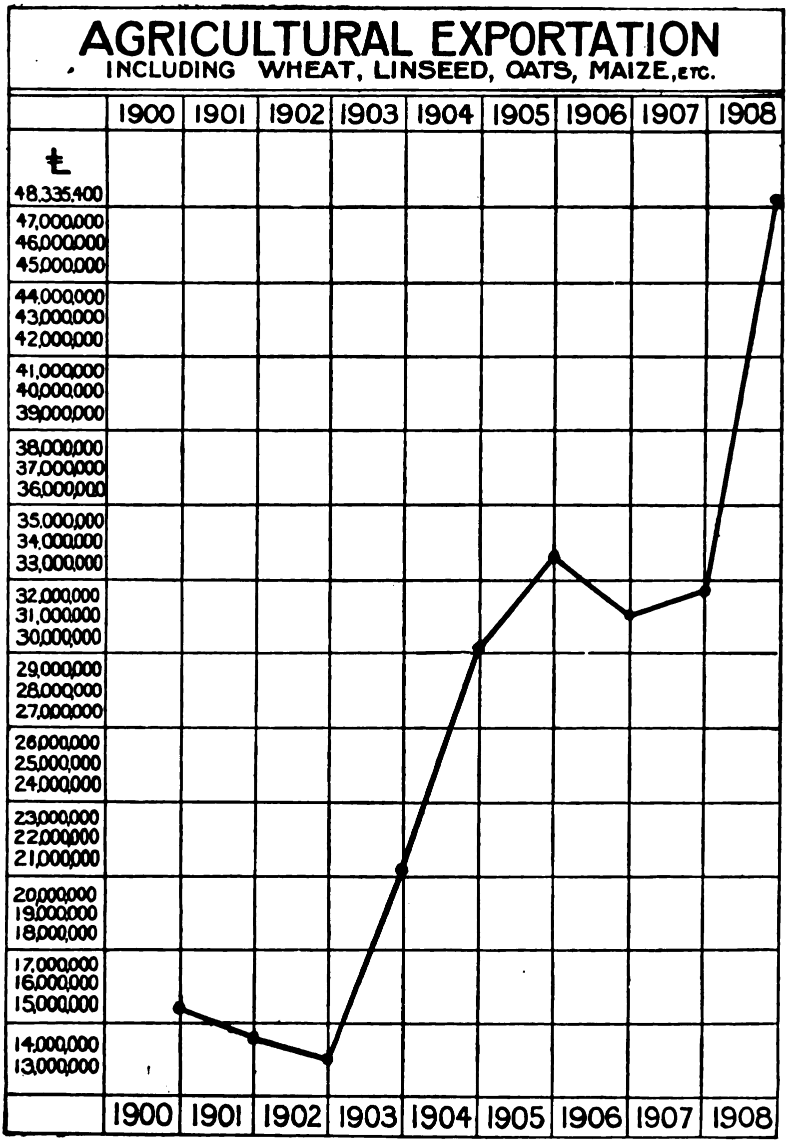
The cost of growing alfalfa greatly depends upon the situation of the land to be dealt with; also upon whether labour is plentiful or not; but, in order to give some idea of the advantage of growing this cattle food, we will imagine the intrinsic value of the undeveloped land to be £4,000, upon which, under existing conditions, it would be possible to keep 1,000 head of animals, whereas if this same land were under alfalfa, 3,000 to 3,500 animals would be fattened thereon, and the land would have increased in value to £20,000 or £30,000.

Now, if the undeveloped land is to be improved, it becomes necessary either to work it yourself, with your own men, in which case you must provide ploughs, horses, bullocks, etc., or to carry out the plan usually adopted, that of letting the land to colonists who have had some experience in this class of work. Usually a colonist will undertake to cultivate from 500 to 600 acres, and agrees to pay to the landowner anything from 10 per cent. to 30 per cent. of his crops, according to the distance of the land from the railway. The colonist brings his agricultural tackle along with him, and establishes his house (usually a most primitive affair), digs his well, and then proceeds to plough. In this work the whole family joins; the father leads the way, followed by the eldest child, and all the others in rotation, with the wife bringing up the rear; she keeps a maternal eye upon the little mite, who with great gusto and terrific yells manages somehow to cling to the plough and to do his or her share with the rest. Is it to be wondered at that work progresses fast under these conditions? There is but one idea prevalent in the family—namely, that time and opportunity are with them.

The first crop grown on newly-broken ground is usually maize; the second year's crop is linseed, and perhaps a third year's crop—probably wheat—is grown by the colonist before the land is handed back to the owner ready to be put down in alfalfa. The colonist's cultivation of the land will have effectually killed off the natural rough grasses which would otherwise grow up and choke the alfalfa. Sometimes the alfalfa is sown with the colonist's last crop, and in such cases the landowner finds the alfalfa seed, and during the sowing of this crop it is very advisable that either he or his agent should be in constant attendance, because the after-results greatly depend upon the care with which the seeding has been done. When the colonist's contract is completed he moves on to another part, and the owner, who has year by year received a percentage of the crops, takes back his land. Considerable outlay has now to be made in fences, wells, and buildings; the more there are of these the better, the land will carry a larger head of cattle, and the control of them is easy when the camp has been properly divided.

The colonists are generally Italians. They are an industrious and kindly people, hardy and quiet, well content with their surroundings, careful and frugal in their living, and many thousands could go back to their own country

TABLE II.



with wealth which has been acquired by constant and assiduous attention to the economies of life.

It has often been said that an Englishman will starve where an Italian will thrive, and in some respects this is true; but it would be better expressed if it were stated that an Italian can adapt himself to circumstances better than an Englishman. At the same time I doubt if an Italian would come off best were the two placed on a desert island where instantaneous action, grit, and endurance were called for.

Many things are said of an Englishman, and none fits his character better than that which gives him the privilege of "grumbling," and this characteristic becomes more marked when he is able to grumble with one of his own kith and kin. I have heard Argentines praise Englishmen —who, they say, manage their estancias far and away beyond all others—but at the same time they have told me that they would never allow two Englishmen on their place at once.

It has been said that many of the immigrants do not intend to settle in the country. Probably this idea has gained ground on account of the large numbers of the labouring population, who are attracted to Argentina by the high wages ruling during the harvest time, and then find it pays them to go home and secure the European harvest, but generally these men come out again to stay. They have acquired a knowledge of the country, and often enough have also acquired an interest in some land, and they return, bringing their families, to adopt Argentina as their home for a period at least.

A glance at the statistics prepared by the authorities in Buenos Aires shows that during the last fifty-two years 4,250,980 persons entered as immigrants, and out of this number only 1,690,783 returned, leaving in the country 2,560,197 individuals, or an average of 50,000 workers per annum. These figures have become even more marked of recent years. Taking the last five years, the country has received on an average 249,000 immigrants per annum; of these, 103,000 went back. In other words, 727,670 have made their homes within the borders of Argentina during the past five years, and of these at least 500,000 were agriculturists.

It is not to be wondered at, then, that the exports, chiefly made up of agricultural produce, have shown extraordinary progress. Table II. is a diagram showing the agricultural exportation from 1900 to 1908.

Nothing can be more eloquent than the figures shown in Table II. This remarkable progress, almost steady in its upward march, is not in one direction only. Argentina is an ideal country for agriculturists, and in every branch of that industry progress has been made. Greater care is being taken to-day in working up the by-products of the cattle business. More varied crops are being grown, and vegetable by-products are being economically looked after. The forests of Argentina are also being worked for the benefit of mankind. The quebracho colorado tree forms a very important item of export. It is sent out of the country either in the form of logs, of which no less than 254,571 tons were exported in 1908, or in the form of an extract for tanning purposes; 48,162 tons of this extract were made and exported in 1908, and a small quantity of the wood was exported in the shape of sawdust. The total value of quebracho colorado exported in various forms in that year was, as already stated, £1,200,000. This means that the quebracho forests are being depleted at the rate of half a million tons per annum for export purposes alone, in addition to the enormous quantities used for sleepers, etc., in the country.

The area in acres under cultivation for the year 1908 was 46,174,250, an increase of 265 per cent. on the land under cultivation in the year 1895.

Table III. shows the area in hectares cultivated from 1897 to 1908.

Wheat.—The area under cultivation for wheat shows an increase of 89 per cent. in ten years from—

8,000,000 acres in cultivation in 1898, to
15,157,750 „ „ „ „ 1908

Linseed shows an increase of 361 per cent. from—

831,972 acres in cultivation in 1898, to
3,835,750 „ „ „ „ 1908

Maize increased by 250 per cent., and other crops, including oats, 300 per cent. in the same period.

The United Kingdom purchased from Argentina and retained for its own use (in round figures) during the year 1908—

Wheat . . .	to the value of	£13,000,000
Maize . . .	„ „	5,600,000
Frozen Meat .	„ „	9,300,000
	Making a total of	£27,900,000

Indeed, we buy from Argentina nearly 25 per cent. of our total food purchased abroad, and she supplies nearly 29 per cent. of our corn and grain requirements. These figures again clearly demonstrate that we have a vital interest in the well-being of our friends across the sea.

In every direction Argentina has progressed, and judging from the past we may look with confidence to the future; the total area of the Republic is 776,064,000 acres, and certainly it is within the bounds of reasonable forecast to consider that 100,000,000 acres of this land will be, when opened up by railways, and other facilities, available for corn growing. To-day only one-fifth of this available area is being cultivated, and another 43,000,000 acres are being utilised for feeding purposes; thus only 63,000,000 out of 776,000,000 acres are being occupied. The chief reason why more is not utilised is because there is not sufficient labour available.

	Inhabitants per square mile.

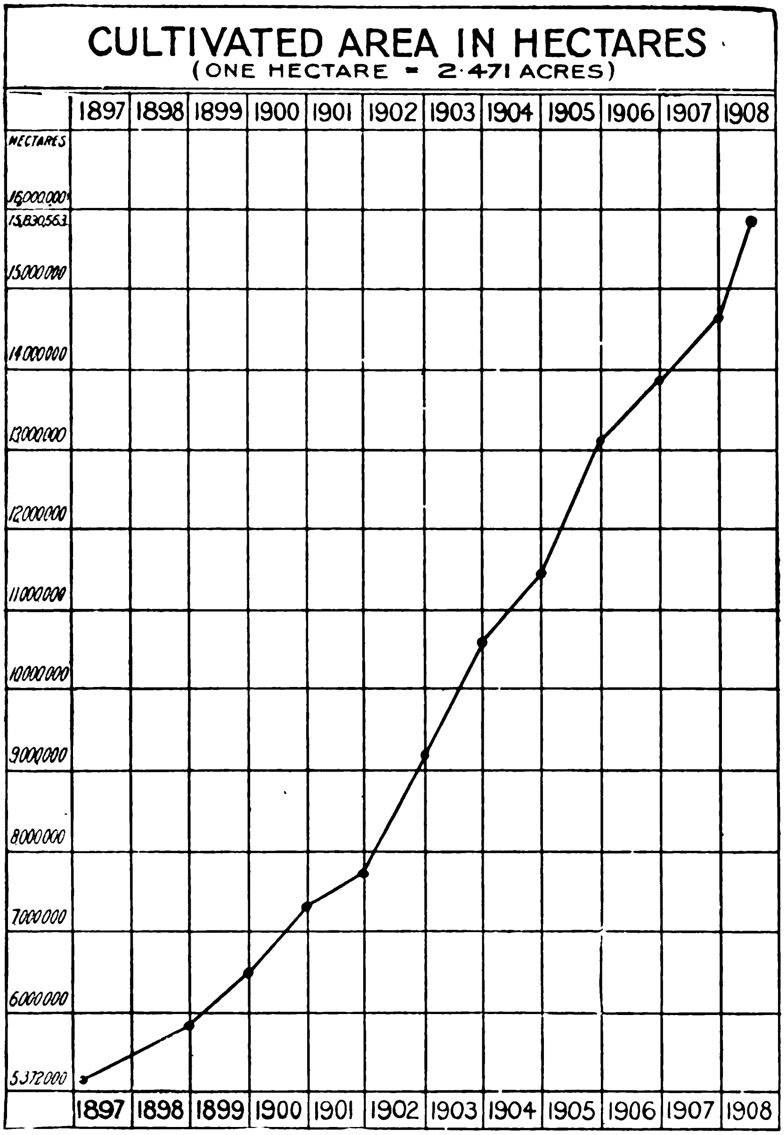
Germany	„ 290

Not only is there an enormous tract of land lying dormant, but the productive power of land now under cultivation may be vastly increased if farmers will devote their attention to improving the conditions of cultivation. 11·3 bushels of wheat per acre is not high-class farming, yet this is the average production for Argentina. Manitoba in 1908 produced 13½ bushels per acre, Saskatchewan, 17 bushels. In the fourteenth century England only produced 10 bushels per acre, but we have improved this yield to 30 bushels, while Roumania has increased her yield from 15 bushels per acre in 1890, to 23 bushels in 1908. France has increased her yield from 17 bushels in 1884, to 20 bushels in 1908. Germany has increased her yield per acre from 20 bushels in 1899, to 30 bushels in 1908. So that we may not only look forward to a greater area being placed under cultivation,

TABLE III.



but we may reasonably expect heavier crops, if land proprietors will bring science to bear on their work of development. Indeed, with land rising in price, with an increasing influx of immigrants and with more intelligent cultivation of the soil, the land must of necessity give a far larger yield than it has done heretofore.

The following tables, taken from the Board of Trade returns, show from whence England draws some of her supplies. They also show how prominently Argentina figures as a food producer. The first table includes corn and meat; the second gives corn alone, and the third meat alone :—

FOOD IMPORTED INTO AND RETAINED BY THE UNITED KINGDOM IN 1908.

Corn (including wheat, barley, oats, rye, buckwheat, peas, beans, maize, wheat-meal, flour, oatmeal, and offals	£71,103,487
Meat, fresh and frozen (including animals for food)	48,704,613
Total	£119,808,100

Meat	Nil.
New Zealand—	
Corn, etc.	£30,585
Meat	£4,168,649

The lesson shown here is one worthy of attention. We see that Argentina supplies England with one-fourth of her imported food, and U.S.A. supplies nearly one-third. Therefore it behoves both England and Argentina to see that America does not so manipulate things that she acquires the control over our meat and food supplies.

Argentine authorities should not only exercise the law sanctioned February 4th, 1907, concerning the inspection of factories, but they should enforce greater care in seeing that all Argentine saladeros and packing-houses are manipulated with intense care, and cleanliness should be insisted upon; it would be a bad day for Argentina should ever such an outcry be raised against her saladeros as that which a few years ago was directed against the North American packing-houses and for a time ruined the canning industry of the United States, and yet we find American methods being introduced into Argentina without let or hindrance. If our soldiers and sailors are to be fed upon canned meats, let those who are responsible for purchasing the food at least see that it is prepared under healthy and sanitary conditions.

The corn-growing industry of the Argentine Republic is an intensely interesting subject. Before railways and steamships brought the foreign producer into close competition with our own farmers, Argentina did not produce enough grain to supply her home consumption, and cattle were bred only for their hides, tallow and bones. In the course of time, when steamers superseded sailing ships and the world's carrying capacity thus became enormously increased, Argentina saw her opportunity of becoming a keen competitor in the food market. Corn-growing became a highly remunerative business, although much still remains to be learned con-

* A list of the other Colonies and Foreign Countries which largely contributed to this total will be found on p. 52.

cerning the handling of wheat. Both in the States and Canada grain is handled in a cheaper and more expeditious manner than in Argentina. An enormous amount of grain is dealt with in the Wheat Exchange of Winnipeg, but a further big impetus will be given to this industry when the wheat-fields of Alberta, Saskatchewan, and Manitoba are connected with a deep-sea port on Hudson Bay; this will be an accomplished fact in 1915, and as this route means a thousand miles less haulage by land, and eight hundred less by sea to the chief European ports than by any existing route, it is bound to become the popular one; the chief factor, however, in making it a useful wheat outlet is the established fact that Hudson Bay, although many miles north of Lake Superior, remains free from ice for a period of one month after Lake Superior is tightly frozen up.

Argentina may look forward to keen competition with Canada and Siberia for many years to come; on the other hand, the U.S.A. will steadily show a smaller quantity of wheat available for exportation. The following table throws some light upon the wheat position:—

Argentina and Uruguay have increased the area of their wheat-growing land brought under the plough in the last ten years by	124	per cent.
Canada in the last ten years by	120	,, ,,
Russia ,, ,, ,,	27	,, ,,
United States ,, ,,	14	,, ,,

No country in the world has shown such wonderful capabilities for growing linseed as the Argentine, and her average production for the following five-year periods show this expansion:—

Years.	Production in Tons.
1894-1898	193,000
1899-1903	382,000
1904-1908	839,000

In ten years she increased her production by 335 per cent. In the same period India increased her production by 3·8 per cent., and North America by 105 per cent., whilst Russia was unable to keep up her supply.

The world's total linseed production for 1908 was made up as follows:—

Argentina produced . .	1,101,000	tons.
North America ,, . .	694,000	,,
Russia ,, . .	470,000	,,
India ,, . .	360,000	,,

Here again we find Argentina leading. Moreover, she exported nearly the whole of her production, whilst North America, Russia, and India exported less than half a million tons between them.

It is more than probable that by 1920 Argentina will be able to export, as the result of agricultural work, more than £100,000,000 worth of produce per annum. It is interesting to note that, as the present figures reveal, allowing for a population of 6,500,000 and an agricultural produce export of £48,335,432, each individual in Argentina has sent abroad, after producing enough from the land to keep himself, goods to the value of nearly £8.

Table IV. shows what has been accomplished by Argentina in the last ten years.

In actual money value the exportation of wheat, linseed, oats, maize, other grain, flour, bran, and middlings is, in round figures, as follows:—

1900	£15,485,000	1905	£34,047,000
1901	14,319,000	1906	31,530,000
1902	13,634,000	1907	32,818,000
1903	21,050,000	1908	48,335,000
1904	30,065,000	1909	46,100,000

CATTLE.

The value derived from the cattle industry and its allied produce is of great importance to the Argentine Republic. The exports from this industry may be divided into four heads, namely:—

Live Animals;
Raw Products;
Manufactured; or
Partly Manufactured Material and By-Products.

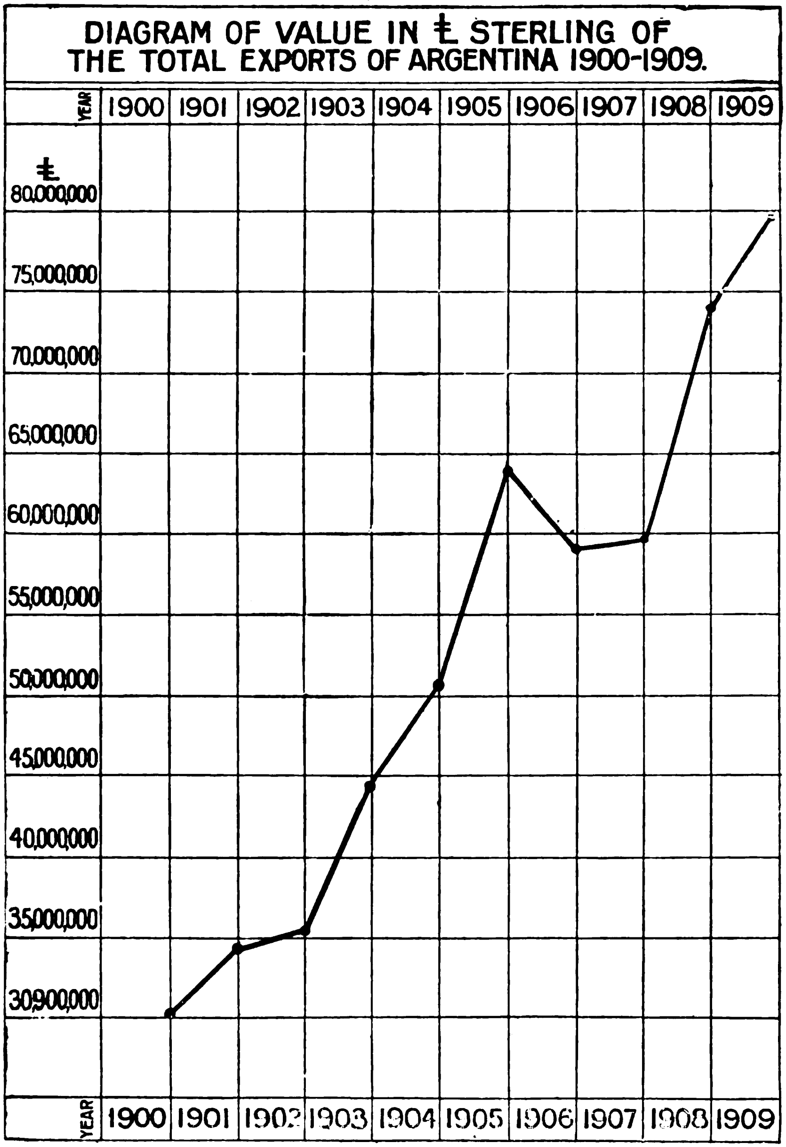
Since the closing of English ports in 1901 to the importation of live cattle from Argentina, the trade in the export of live-stock has fallen off considerably; the total value did not in 1908 amount to more than £568,966; Belgium took 65,224 sheep, Chili took 45,114 cattle and 14,394 sheep, Bolivia took 3,383 head of cattle and 10,676 sheep, and 16,000 asses and mules, while horses were imported into England, Africa, Portugal, Brazil, Uruguay, Chili, Bolivia, and Paraguay.

Exports of raw products, which include frozen and chilled beef and mutton, hides, sheepskins, wool, and such things as horsehair, tallow, jerked beef, etc., represented a value of £19,549,231 in 1908.

Manufactured or partly manufactured material, including prepared tallow, meat extracts, meat, butter, cheese, lard, dressed leather, etc., represented £2,454,760, whilst the by-products, including bones, dried blood, guano, waste fats,

etc., were valued at £430,734. Thus Argentina's total export from the cattle industry (after supplying her own needs) was over £23,000,000.

TABLE IV.



Argentina's live-stock on hand when the last census was taken in May, 1908, was as follows:—

Cattle	29,116,625
Sheep	67,211,758
Horses	7,531,376
Mules, swine, goats, and asses .	6,098,802

representing in value £129,369,628.

The favourite breed of cattle is the Shorthorn, and they comprise 84 per cent. of the classified breeding cows; the Herefords only figure out as 6 per cent., but, undoubtedly, a more careful and complete classification will lead to modifications in these figures, for at the present time no less than five and a half million cows are returned as Criollo cattle—in other words, unimproved stock.

Not until the year 1885, when it became possible to send frozen meat to Europe, did estancieros pay serious attention to growing cattle for meat production, and now, with an ever-increasing quantity of land being placed under alfalfa, the Argentine Republic is fast becoming

the leading factor in the production of meat to satisfy the world's consumption.

Cattle on the outside fringe of occupied lands are still very coarse and rough, with a distinct strain of the Hereford about them; they are, however, a useful herd and most suitable for the districts they occupy, where they often have to undergo the hardships of shortage of pasture owing to drought, and little or no water. Indeed, it is a marvel how these animals exist at times; and assuredly no refined breed of cattle could live where the Criollos not only manage to thrive but generally to return a satisfactory result to their owners. The cattle on ranches which are nearer to the seaports, manufacturing centres, or railway stations, show distinct improvements. Greater care is bestowed upon them, and the main consideration is never lost sight of—it is the ambition of every estanciero to have his cattle graded up so that they are looked upon as "freezers," which means that they are good enough to be purchased by one or other of the refrigerating companies, who take nothing but the best.

In 1888 cattle running the northern camps (which then represented the extreme outlying posts) were only valued at $6 per head.

In 1890 the value had risen to $10 per head.
„ 1900 „ „ „ 15 „
„ 1908 „ „ „ 28 „
„ 1910 „ „ „ 40 „

The question of stock-raising and the object to be obtained must rest with the owners; they must decide whether the land is to be utilised for fattening cattle or for breeding the high-class animals for which there is an ever-ready market. To show the enormous value of animals and the high standard to which agricultural lands can be brought, mention must be made of two estancias near Buenos Aires—viz., those belonging to Messrs. Cobo and Messrs. Bell, where splendid stock is always to be found. To give some idea of the high price paid for first-class pedigree animals, it may be mentioned that £3,800 was paid for a prize Durham bull which was sold to Argentina!

At the cattle show at Buenos Aires held in July, 1910, Herefords for killing realised from £850 to £1,000 per animal! These latter high prices were, however, evidently paid by the agents of cold storage companies for advertising purposes. One representative explained that the freezing companies desired to encourage breeders, and that his company paid the high prices mentioned above so as to let the breeders know that they would always be paid high prices for first-class cattle.

When we consider the really important position which Argentina takes as a food producer, it appears incredible that the English nation (business men and the general public alike) is so extremely ignorant, as a rule, of prevailing conditions. I do not refer to those who have invested their money in the many channels known to the River Plate circle. But men holding high official positions speak of our commercial interests in Argentina as "something between a hundred and a hundred and fifty millions," and then in a whispered side-speech indicate the dangers of revolution.

Often it is suggested that the chances of death from small-pox, yellow fever, and even from murder, are a serious drawback to what might otherwise be a country possible to live in. It makes one very indignant to hear these statements from the lips of those who probably have never left their own country. Let me assure you they may be swept aside, and were it not for their frequent reiteration it would be unnecessary to say that there is not one grain of truth in these suggestions as applied to the state of things to-day.

Nearly one-fifth of the population of Argentina is centred in and around Buenos Aires. It is a city of 1,200,000 inhabitants, many of whom are millionaires, but at the same time there exists much poverty within its precincts; poverty caused in no small degree by the viciousness of the rich, but to a far greater extent by the rooted objection of certain classes to go out to the camps where, during the harvest time at least, wages are high and labour is anxiously awaited.

When we compare the health of this city of Buenos Aires with that of other large cities, we can see what has been done in the way of improvements in the last few years. A glance at the following tables will give some idea of what has been accomplished. The natural increase of the population of Buenos Aires between 1898 and 1907 was 19·1 per 1,000, and no other city equals this.

		Per 1,000 Inhabitants.
The increase in London	. . . . was	8·8
„ „ Berlin	. . . . „	8·5
„ „ New York	. . . „	5·7
„ „ St. Petersburg	. . „	4·6

The birth-rate of Buenos Aires for	1908 was	34·3
„ „ London „	„	25·7
„ „ Berlin „	„	23·3
„ „ New York „	„	28·5
„ „ St. Petersburg	„	27·5

Both these tables are, however, probably affected by the great number of immigrants finding their way to Argentina, many of whom remain in Buenos Aires.

The health of the city may be well gauged by the death-rate for the year 1907.

	Per 1,000 inhabitants.
Buenos Aires stands well with . .	15·2
London has a death-rate of . . .	15·1
Berlin ,, ,, . . .	14·8
New York ,, ,, . . .	18·6
St. Petersburg ,, . . .	25·7

(Undoubtedly the high rate shown by the last-named city is greatly due to the foul condition of the Neva.)

To appreciate thoroughly the position which Buenos Aires now holds, and the strides which have been made in regard to the sanitation of the city, we have but to look at the past. Between the years 1889 and 1898 the death-rate per thousand was as high as 22·9 per 1,000; from 1899 to 1908 it was only 16·6, and now the record stands at 15·2 per 1,000.

The authorities are justly proud of what has been done, and will not diminish their efforts so long as there is work to do and problems to solve.

I should like to state once more the fact that the United Kingdom depends upon Argentina for nearly one-fourth of her food supply purchased abroad. I want to impress upon your minds the seriousness of the position, for this proportion of one-fourth will be largely increased in the near future, for reasons already stated.

The question has often been asked, "Is it safe to buy land in Argentina?" But the drift of this query too often is merely self-interest; in other words, it really means "Can I successfully speculate in land?" Clearly the matter is solely a personal one, no other consideration is thought of, so one is tempted to give an evasive answer. Should the questioner, however, be a young fellow, with God's gift of health and plenty of truth and grit in him, who wants not only to acquire the land, but to work it, then, indeed, there is but one answer, and that is in the affirmative—let him go, and let him ever remember that he is an Englishman and that England is judged by the conduct of her sons, but do not let him make the great mistake a newcomer so often falls into, which is, that because he is an Englishman all other nationalities must be inferior, and that by some sort of divine right he has been created lord of all. Let him realise that those whom he meets in Argentina are as noble and pure as those he left at home. Argentina offers to-day a splendid opening for the best of England's sons, but she does not want the loafer or the ne'er-do-well. Can it be wondered at that England's prestige is seriously injured when so many of the "wasters" and worse are sent from the country? It is but natural that from these who go to foreign countries, England is judged. To my mind, we should send abroad men who are bound to succeed, men who never forget that from their behaviour the Mother Country will be appraised. Argentina will embrace and reward them, but she will spurn and despise the dissolute and drunken.

The advice I would give to all those thinking of trying Argentina as a field for agricultural work is to remember that to be successful one must begin at the bottom: the harder the school the better will be the result: you cannot detect and correct the faults which militate against success unless you have been through the mill. Not long ago I sent a boy out to Argentina and painted the first two years of learning in the new country in rather lurid colours. I explained and dwelt on the hardships—indeed, I described it as "a dog's life." Within a year, the lad wrote home to his parents and mentioned all that I had told him, but finished up by saying, "There's plenty of 'life' about it, but not much 'dog.'" The truth is, that the boy had accepted things as they came along, and had adapted himself to his surroundings, and, I predict, he will never regret having left his home, where opportunities were cramped by small surroundings, for the wider field of Argentina.

A great many Englishmen resident in Argentina, whose sons are looking forward to finding their life's work in that country, send their boys home to England to be educated: far be it from me to deprecate the training acquired by English public-school life, but it might well be worth while to consider the other phase. The boy who has had his schooling in Argentina and goes through his training and passes into one of the local universities will have to his credit something which cannot be bought by money or influence by boys straight out from home. He will have been a fellow-student, and worked shoulder to shoulder with men who will in due time occupy positions of power and influence, and it is just as well to weigh out these things before deciding where to educate your boy. A boy born in Argentina, whatever the nationality of his parents may be, is by Argentine law an Argentine subject, and should be brought up to appreciate that he is liable to be called upon to

go through a military course: the Argentine boy, who has had just as gentle an upbringing as the English boy, is compelled to serve his time in the army if called upon, and generally the discipline engendered by this training has not only been good for him, but is a distinctly valuable asset to the country, and the English boy, as well as a boy of any other parentage born in the country, will be obliged to go through this military training if required.

I venture to think that were England to adopt compulsory military service in some shape or form, we should hear a great deal less of the unemployed and "don't-want-work" demonstrations.

To attempt to give a picture of Argentine life is impossible in the short time at my disposal. Imagine to yourself, if you can, a country of 1,212,600 square miles, whose borders extend from well within the tropics to away down south to the everlasting snows, embracing all kinds of lands, from the very richest of soils to ice-capped and rocky peaks, and you must admit that to attempt to describe the various conditions of life therein is well-nigh impossible. Life is much what the surrounding conditions make it—on the extreme edge of cultivation it is distinctly rough, on the inner camps refinement steps in, and in the cities you will find just what society you wish. Amongst the cosmopolitan population of Buenos Aires there are many men and women of the highest culture and education.

There are many Argentines, standing out prominently from the throng of busy pleasure-seekers, who are devoting their lives to improving the surroundings of those less fortunate fellow-creatures who have fallen upon the thorny path, and whose portion is often the cup of bitterness. Indeed, I have ever found the Argentine desirous of helping those who seek advice and assistance, but he spurns the foreigner who degrades himself and his country by acts of folly which would not be permitted in his native land.

Englishmen often fall into the great error of keeping themselves to themselves. Possibly this trait is engendered from birth and training by our insular position, but it is a great pity to carry it too far, for the Argentine people do appreciate the thoroughness of our countrymen, and are ready to welcome the right sort. We have taught the Argentines many of our national sports and games, and they have entered into them with such thoroughness that the teachers have often had to admit that the pupil has proved better than the master.

Travelling has become an integral part of the education of the Argentine family to-day, and it is quite general to find young children speaking fluently four or five languages.

I could wish that those who have Argentine friends would insist upon their seeing, when in this country, some of the Englishman's home surroundings; for hotel life, theatres, dinners, and music-halls are all very well in their way, but to see the real inwardness of English life you must follow the Englishman to his country home. My experience is that the Argentine will always refuse an invitation to your home at first, because of the trouble which he believes you will be put to, but don't take "no" for an answer; simply make him come, and he will thank you afterwards for his experience of English home life.

Just a word or two, for fear I have left an impression that Argentina is the El Dorado which lies beyond the seas. There are such things as locusts, floods, droughts, and frosts in that country.

The first of these—locusts—are indeed a plague which to-day it seems almost impossible to annihilate, for I have little faith in man's attempts effectually to stop or decrease this pestilence; on the other hand, Nature always seems to be on the alert to prevent an overthrow of the balance of things; those who have spent their lives in the River Plate district have seen this appalling plague crushed by means which Nature, in her own good time, has thought fit to use.

With regard to floods and droughts, these can, at least, be modified by men, and means are now being adopted to conserve the floods and render their waters available in time of drought.

From frosts we seem powerless to defend ourselves, and it is only those whose work is in close touch with the growing and handling of crops who can fully appreciate the damage done by late frosts.

No country is free from drawbacks of some sort or another, and these troubles which I have just mentioned will not prevent the forward march of progress in Argentina.

The Chairman, in proposing a hearty vote of thanks to the author for his interesting and instructive paper, and the series of remarkable cinematograph and lantern-slides with which it had been illustrated, said he had had business relations with Argentina for a number of years, but unfortunately, like many other Englishmen who had relations with the country, he had never had an opportunity of paying a visit to the River Plate. The author was very desirous of bringing before the British public the fact that in the Argentine there was an almost illimit-

able field for British enterprise. At the present time some hundreds of millions of British capital were invested in the Republic, and it seemed probable that that amount would be doubled in the course of a very short period. During the last ten years the developments of the River Plate had been upon a colossal scale. He had recently read "The Life of Sir Woodbine Parish," a book which dealt with the early period of settlement in Argentina, going back to the beginning of the last century; and it seemed almost impossible to imagine that the country there described could be the same as that with which the author had dealt in his Paper. One hundred years had made a marvellous difference in the country, its growth in the last ten years being altogether extraordinary.

The resolution of thanks having been unanimously carried, the meeting terminated.

COTTON-GROWING IN FRENCH COLONIES.

The French Colonial Cotton Association is meeting with much encouragement in its efforts for the cultivation of cotton in Senegal, Upper Senegal, and Dahomey. As yet the output o cotton in these colonies is not large, but the work of experimentation has been in progress only seven years. The area under cultivation and the yield have increased with each season, as the Association gradually extends its work and the natives become more and more familiar with the methods of preparing the soil and harvesting. In 1908 the crop was 780 bales, while in 1909 it increased to 1,085 bales. In some of the French colonies irrigation is necessary, especially in Senegal, and possibly in Algeria, but in the rest of those vast African regions controlled by the French and British Governments the rainfall is sufficient. With so much money being expended under the direction of experienced agents, and with an abundant supply of native labour, the predictions of those interested in the work appear reasonable, and it seems probable that in the course of time Africa will produce, outside of Egypt, several million bales of cotton each year. In the French Cotton Association's report it is stated that in 1909 the Association began the installation and equipment of two ginning plants, one at Noumea and the other at Richard-Toll. Each of these stations is supplied with a petroleum motor, two rotary gins, and a hydraulic press. In Dahomey the work is virtually completed. Two small hand machines have been sent to the Ivory Coast, and a new roller gin has been supplied to the station at Philippeville, Algeria. In the Sudan a new station has been installed at M'Psoba in the Koutiala region, which produces an important quantity of cotton, and where it is expected that fifty tons of fibre will be ginned this year. Experiments conducted under the supervision of an Egyptian expert to determine whether cultivation of cotton in Senegal with the aid of irrigation is possible, are thus referred to:—"Two hectares (about five acres) at the station were laid out, broken up, fertilized with farm manure and chemicals, and planted with several Egyptian and American varieties. At the same time ten hectares (about twenty-five acres) of the surrounding land were prepared. Trained oxen were scarce and the natives had to be taught how to cultivate the ground. The plant was normal but developed rather more rapidly than in Egypt. The crop reached full maturity. Some of it has already been shipped to Havre to be ginned. The yield is expected to be more than 1,100 lbs. to the hectare (approximately 450 lbs. to the acre). This compares favourably with what is done on the best fields in Egypt. One important result of the experiment will be the elimination of all varieties except the Mit Afifi and some Mississippi cotton in future experiments." Results in the Sudan were entirely satisfactory. About 75,000 lbs. of cotton were exported to France in 1909, and of this 4,000 lbs. were produced by a native who co-operates with the French Colonial Cotton Association. The rainfall during the season was satisfactory, and the yield at all stations in the territory was very good. A new ginning plant is to be established at Koutiala. The Sudan cotton is said to be of excellent quality, and sold in France at a good price. Of Dahomey and the other colonies it is said that, so far as the former is concerned, the results indicate a decided advance, inasmuch as the production is expected to reach 150 tons. The 1909 season was one of excellent rainfall, and the natives considerably increased their plantations of cotton in the certainty that they would be able to sell their crops to the agents of the French Colonial Association. In the other colonies cotton cultivation continues to progress. In south-west Africa the British Government has been assisting in experiments which have been carried on with evident success for a number of years, covering a field vastly larger than that of the French.

HOME INDUSTRIES.

Protection and the Cotton Industry.—Mr. C. W. Macara is an acknowledged authority on the cotton industry, and he has just published a statement respecting the effect of Protection upon that industry which deserves careful study. Our pre-eminent supremacy in the neutral markets—Turkey, Persia, India, China, South America—which form the backbone of our export trade, is admittedly due to the low cost of production; and low cost of production is due not to low wages and long hours of labour—wages are higher and hours shorter in Lancashire than in any cotton manufacturing district in the world—but to an economical first outlay on business and machinery, to highly efficient labour, to efficient specialisation in the

various processes of the industry, and to the fact that the many industries subsidiary to the cotton trade, and dependent upon it as their market, are themselves, under present circumstances, able to supply the cotton trade with their productions at the lowest cost. Assuming that the effect of a policy of Tariff Reform would be to raise by 5 per cent. only the cost of such materials as tools, timber, cement, glass, paint, leather and machinery, Mr. Macara puts the added cost of equipping a cotton mill of 80,000 spindles at £3,750, and the extra charge in working expenses at £613 a year, while a rise in such prices by 10 per cent. would increase the first outlay to £7,500, and the annual working expenses by £1,226. A proportional added first cost and extra working expenses would be incurred for weaving sheds. For bleaching, the addition to the cost of production on a 5 per cent. rise in cost of building and materials Mr. Macara puts at 2½ per cent., and, on a 10 per cent. rise, 5 per cent.; while in a printing and dyeing business employing a plant worth £50,000, a 5 per cent. rise in materials would mean an addition to cost of production of from £1,500 to £2,000 a year. In addition, there would be the rise in charges for railway carriage following on the general increase in the cost of living. What is the margin of net profit in the cotton industry? Mr. Macara puts it at 5 per cent. only. If that is so, and Mr. Macara's calculations as to the increased cost of production through Protection are trustworthy, the effect of the acceptance of Tariff Reform would be in some branches of the cotton industry to extinguish altogether any return on the capital invested, and in others to reduce that return to so low a point that no new capital could be attracted to it. Assuming Mr. Macara to be correct in his figures, his conclusion that a protective system would be a death-blow to the cotton industry can hardly be contested. And on the cotton trade, and the trades related to it, depends a population of not less than 3,000,000 people—one in every ten in England and Wales.

The Scottish Mineral-Oil Trade.—Recently the Standard Oil Company made certain minor concessions with the view of attracting the custom of contributors. Now the Scottish Oil Company have announced the increase of the allowance for returned barrels from 5*s.* to 5*s.* 3*d.* each as a counter concession. The days of the wooden oil barrel are probably numbered. Distribution by tank-waggon is steadily growing in favour with both wholesalers and retailers, it being recommended by its greater convenience, cleanliness, and economy. But certain vested interests seem to be blocking the way to a general adoption of a very desirable reform.

The Rise in Glycerine.—During the last eighteen months the price of glycerine has risen over 50 per cent., and last week the highest price on record was touched, there being a further advance of £5 per ton. This great rise in price affects many industries, and is said to be due largely to the scarcity of fats and oils from which glycerine is made as a by-product in the manufacture of soap, and the increased demand for glycerine for the manufacture of high explosives, great quantities of which are required for the construction of the Panama Canal and other great engineering works.

The Boilermakers' Lock-out.—This lock-out continues without any signs of early ending, and with great loss to all concerned. The men are said to be more determined than ever in their opposition to the terms of the York agreement, and it is said that there has been a substantial response to the appeal for funds to support them. But no response, however liberal, can do very much to alleviate the hardships caused by the lock-out. The boilermakers have been getting ten shillings per week for fully-qualified members, but that can no longer be paid, and the boilermakers when at work are amongst the best paid of artisans, earning from £3 to £5 per week. It is impossible to measure the loss already incurred by the shipbuilding industry owing to the lock-out. Many orders for new ships from foreign owners have been lost, and much repair work, and work under surveyors for classification purposes, has had to be sent to foreign yards. And of course it is not only the shipbuilding trade that is suffering. When the shipyards are idle many trades suffer. Now that the shipyard ironworkers have been idle for three months, woodworkers, painters, cabinet-makers, brass-founders and finishers, plumbers and many others, are out of employment, and this necessarily restricts the several productive industries with which they are associated. Shopkeepers, too, both wholesale and retail are suffering. It is estimated that the dismissed members of the Boilermakers' Society have lost in wages in the three months as much as half a million sterling, and quite possibly more, and this loss of wages is only a part of the loss in circulating medium in the form of wages, for the loss of wages in other branches of the industry by consequent unemployment must now be very heavy. And the effect of the lock-out on the iron and steel industries is most serious, for in the neighbourhood of the shipbuilding districts at least 50 per cent of the production of the steelworkers is in shipbuilding material.

Produce of Crops.—It appears from the Preliminary Statement showing the estimated total produce and yield per acre of the corn, pulse, and hay crops in Great Britain in 1910 that the wheat crop of the present year was much worse than in 1909, a fact that will surprise many. The average estimated yield per acre was only 31·10 bushels as against 33·61 bushels in 1909, and 31·47, the average of the ten years 1900–1909. The acreage, too, shrank from 1,734,236 to 1,716,629.

Nevertheless the total production of wheat, while less than last year by about 600,000 quarters, is above the ten years' average, mainly in consequence of an increase of acreage in recent years. Barley is slightly above the average yield in Great Britain, but it is less than in 1909 by three bushels per acre. Oats are the best of the corn crops, with a yield per acre of over one bushel above average. The hay crop, both from arable and meadow land, is above the average by nearly 2 cwts. per acre in the one case and 1½ cwts. in the other. Altogether, 9½ million tons of hay were grown this year as compared with less than 8½ million tons in 1909. The average annual production is about nine million tons. Another Preliminary Statement just issued gives the estimated total produce and yield per acre for the potato and root crops. The most striking feature of the latter return is the decrease in the acreage under potatoes. The yield per acre was slightly larger than in 1909, and 10 cwts. above the decennial average, but owing to the reduction in acreage the total crop is smaller by 200,000 tons than last year, and nearly half a million tons less than in 1908. The acreage fell from 3,674,453 to 3,478,289 acres, but the shrinkage is almost entirely confined to England and Wales.

CORRESPONDENCE.

YERBA (OR MATÉ) TEA.

In reference to the notice in the Society's *Journal* of November 25th, I think it worth while to point out that the "tea" is valuable to dyspeptics, from the almost entire absence of tannin. Also I have had independent testimony that it possesses a food value or sustaining power resembling that of the kola nut. The small stalks as well as the leaves are dried and ground more or less finely, but scarcely to the extent of pulverization. Another advantage is that it will bear re-infusion or decoction. Milk is unsuitable; and to my taste the beverage is at its best with sugar and a small slice of lemon in the cup.

The flavour is generally liked by Europeans after a few days' use. JOHN RYLE.

OBITUARY.

DORABJEE PESTONJEE CAMA.—Mr. Dorabjee Pestonjee Cama died at his residence in Notting Hill on Wednesday, November 23rd, at the age of 78. Mr. Cama became a member of the Society in 1871, soon after he settled in London, and in association with Mr. M. H. Cama, Mr. K. R. Cama, and Mr. Dadabhai Naoroji, who still survives, established the firm of Bombay merchants which soon became the leading Indian firm in London of that character. Mr. Cama was highly respected by his compatriots, and for many years past was considered the head of the Parsi community in London. He acquired considerable wealth, which he employed in many charitable works, including the building of the Cama Hospital for Women, Bombay, and was a liberal subscriber to the Masonic and other charitable institutions. He was the founder of "The Zoroastrian Fund," now known as "The Parsi Association of Europe," and to the last was one of its principal supporters. He was buried in the Parsi cemetery at Brookwood last Saturday, the 26th November.

ALEXANDER ROGERS.—Mr. Alexander Rogers, late Bombay Civil Service, died at his residence in Clanricarde Gardens, Bayswater, on the 27th ult. He was appointed from Haileybury in 1845, and, after serving in the Bombay Revenue and Judicial Department, he was appointed collector and magistrate successively at Broach, Ahmadabad and Surat. In 1865 he became Revenue and Police Commissioner, Northern Division, and in 1872 Member of Council, Bombay. He retired from the Service in 1879.

Mr. Rogers, who was well known as a Persian and Indian scholar, translated three modern Persian plays and "Yusuf and Zuleika." He also edited the "Bostan" of Saladi, and wrote a "History of the Land Revenue Settlement of Bombay." He became a member of the Royal Society of Arts in 1878. Since 1892 he served on the Indian Section Committee. He seldom missed a meeting of the Indian Section, taking part in the discussions on many occasions, and he contributed a large number of letters, mainly on Indian subjects, to the *Journal*.

NOTES ON BOOKS.

AN IMPERIAL COMMONWEALTH. By C. Reginald Enock, F.R.G.S. London: Grant Richards. 3s. 6*d*. net.

In February last Mr. Enock read before the Colonial Section of the Society a Paper entitled "Imperial Colonial Development," in which he proposed that each municipality or administrative unit in the United Kingdom should purchase or acquire by other means, a particular tract in the oversea states of the Empire, and that such districts should be developed as settlements for emigrants from the places with which they would be connected. The paper aroused considerable public interest and comment in the press. As it appeared so recently in the *Journal*, it is hardly necessary to recapitulate its principal points. Mr. Enock is an engineer and a traveller who has seen a great deal of the world, especially of its less well-known parts, and he has been deeply impressed with the contrast between the overcrowded state of the homeland and the lack of population in many of our colonies. He also strongly disapproves of the manner in which

various colonial governments bid against one another for desirable immigrants, and give away to persons of all nationalities vast tracts of land which, he contends, are the birthright of the British alone.

In the present volume these various points are developed at length. Perhaps the chief addition is the last chapter. Here he describes the "Commonwealth Council," which he proposes, as an Expert Chamber to undertake "the systematic and scientific conservation and development of the resources of the Empire for the benefit of its people." It is to consist of representatives of various public bodies possessing expert knowledge of the country, *e.g.*, the learned societies, steamship and railway companies, banks, etc.—"in brief, every constituted body of importance should send its delegates, and all should draw professional fees." The first task of this body "would be a scientific, practical tabulation of the land and other resources of the whole Empire. That being done, the principle advocated here of the allotment of areas of fertile colonial territory to organisations of ratepayers, or of municipal authorities, or both, would be brought forward actively. Every encouragement and stimulation would be given for the formation of these, and as far as were desirable the way pointed to the raising of the working capital. The machinery for the semi-penal control of the 'unemployables' as outlined in another chapter would be urged. The tabulation of the capabilities and defects of the home population would run hand in hand with the organisation and development of the Imperial resources."

Mr. Enock writes with much enthusiasm in setting forth his scheme, which, whatever may be urged against it, cannot be said to be lacking in originality and boldness.

Alphabets Old and New. By Lewis F. Day. Third Edition, revised and enlarged. London: B. T. Batsford. 5*s*. net.

The third edition of the late Mr. Day's volume contains no fewer than two hundred and twenty-four alphabets, ranging from the earliest period to the present day. They are disposed as far as possible in chronological order, with a descriptive list giving the sources from which they were obtained, and they are followed by a collection of ancient numerals and some fifty examples of ampersands. An introductory article, entitled "Art in the Alphabet," contains an interesting historical account of the development of lettering to guide the student in his own further experiments in design. A considerable number of modern examples are included, among the designers being Mr. Walter Crane, Professor Selwyn Image, Mr. Walter West, Professor Beresford Pite, and the author himself.

The work has been carried out with that artistic care and completeness which characterised all that Mr. Day undertook, and it should prove of great value to architects, sculptors, designers, draughtsmen, and art-workers generally.

GENERAL NOTES.

The Australian Dried Fruit Trade.—According to the American Consul at Melbourne, the production of currants in South Australia and Victoria in 1909 amounted to 36,378 cwts., and the quantity of oversea fruit cleared for home consumption, duty paid, was 54,162 cwts., so that approximately the total home consumption was 90,540 cwts. In the 1910 season the local production in South Australia and Victoria reached 63,460 cwts., so that it would appear that imports of about 27,080 cwts. of foreign fruit would suffice, as compared with 54,162 cwts. imported in 1909. Thus the gain in local production is an important factor, especially as the crop oversea is reported to be short. It should be noted that the duty-paid clearances of oversea fruit in 1909 were larger than usual. The production of all raisins in Victoria and South Australia in 1909 was 97,543 cwts., of which 7,602 cwts. were exported, and about 2,000 cwts. used for distilling, leaving a net local supply for the market of 87,941 cwts. To this has to be added 8,199 cwts., mostly sultanas, oversea fruit cleared, duty paid. Apparently, therefore, Australia's requirements for consumption in 1909 was 96,140 cwts. In the 1910 season the production of raisins in Australia was 108,852 cwts., so that apparently there was a surplus of about 12,712 cwts. But there have been shipments to New Zealand, and imports of foreign fruit to be considered. The figures of production of the two classes of raisins in the two principal States for the 1910 season were:—sultanas, Victoria, 49,810 cwts.; South Australia, 11,296 cwts.—total, 61,106 cwts. Other raisins:—Victoria, 31,234 cwts; South Australia, 16,512 cwts.—total, 47,746 cwts.

A New Fuel for the Sudan.—The Berlin correspondent of the *Times* sends some interesting particulars of the trials recently carried out at the Christoph Friedrich Works at Merseburg, and by Messrs. R. Wolff at Magdeburg, in connection with a new fuel which it is proposed to manufacture from the rank growths of reed on the upper reaches of the White Nile, locally known as "Sudd." These reeds extend over an area estimated to cover some 35,000 square miles, and the Government have to maintain dredgers to keep channels open through the morass. For some 200 miles it is impossible to secure fuel of any kind, as the river channel has no banks, and the dredgers are dependent for their coal supply on Khartum. The present price of coal, or coal briquettes, at Khartum is about 66*s*. a ton, while wood is little cheaper. "It is now proposed to convert the Sudd itself into briquettes, which can be used as fuel. The Sudd will be cut close to the water level by a machine carried on a boat, which is being specially constructed. It will be chopped in this machine and passed into barges, from which it must be transferred to a station

on shore. After a short period of drying the chopped reeds will be put into machines, called disintegrators, by which they will be ground into loose chaff. From the disintegrators the material will be automatically fed into briquetting machines, by which it will be compressed into the form of briquettes similar in shape and cubic capacity to brown coal briquettes. The machinery employed is simple, with the exception of the briquetting machines, in which a high compressing power is required. It is proposed to instal machines capable of dealing with fifty tons of fuel a day. No foreign binding material will be employed, so that when the initial plant has been installed it is hoped that the expenses for the transport of material will be very small."

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock :—

December 7.—Vaughan Cornish, D.Sc., F.G.S., F.C.S., "The Panama Canal in 1910." Sir William H. White, K.C.B., F.R.S., will preside.

December 14. — Reginald A. Smith, B.A., F.S.A., "A New View of Roman London." George Laurence Gomme, F.S.A., will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock :—

December 15.—Robert Fellowes Chisholm, F.R.I.B.A., F.S.A., "The Taj Mahal and its Relation to Indian Architecture." Sir William Lee-Warner, K.C.S.I., Chairman of the Indian Section Committee, will preside.

Cantor Lectures.

Monday Evenings, at 8 o'clock :—

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Industrial Pyrometry." Four Lectures.

Lecture III.—December 5.—Laws of resistance to electricity—Siemens' resistance pyrometer—Callendar's pyrometer — Principles of resistance measurement—Temperature indicators for resistance pyrometer—Callendar's recorder—Northrup's recorder—Special uses and limitations of resistance pyrometers.

Lecture IV.—December 12.—Radiant energy—The "fourth-power" law—Laws of Wein and Planck—The Féry radiation pyrometers and indicators—The Holborn-Kurlbaum optical pyrometer —Wanner's pyrometer—Other optical pyrometers —Special uses of radiation pyrometers in pottery manufacture and work at very high temperatures.

Papers to be read after Christmas :—

Horace M. Wyatt, "Motor Transport in Great Britain and the Colonies."

Philip Joseph Hartog, M.A., B.Sc., "Examinations and their bearing on National Efficiency."

J. C. Medd, "The Dutch Labour Colonies."

Cyril Davenport, "Illuminated Manuscripts."

George A. Stephen, "Modern Machine Bookbinding."

Professor J. Wertheimer, B.Sc., B.A., "Water-Finders."

Captain A. J. N. Tremearne, "Some Nigerian Head-Hunters."

Hon. Sir Richard Solomon, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "South Africa before and after the Union."

F. Douglas Osborne, M.Inst.M.M., "The Tin Resources of the Empire."

Reginald Murray, "Indian Banking."

R. A. Leslie Moore, I.C.S. (retd.), "Indian Superstitions."

Captain R. Muirhead Collins, C.M.G., "Australia and her Resources."

Frank M. Andrews, "Architecture in America."

Arthur Charles Davis, F.C.S., Assoc.Inst.C.E., "The Manufacture and Testing of Portland Cement."

George B. Heming, "Art Education in Jewellery and Goldsmithing."

Colonel Charles Edward Cassal, V.D., F.I.C., "The Adulteration of Food."

Dr. Leonard Hill, F.R.S., "Caisson Sickness and Compressed Air."

Sir William Abney, K.C.B., D.C.L. D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

Hal Williams, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

Noel Heaton, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

Indian Section.

Thursday afternoons, at 4.30 o'clock :—

January 19, February 9, March 16, April 27, May 25.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock :—

January 31, February 28, April 4, May 9.

Cantor Lectures.

Monday evenings, at 8 o'clock :—

Frederick Wedmore, "Etching": 1. "The Old Masters;" 2. "Modern Etching." Two Lectures.

January 23, 30.

Professor Adrian J. Brown, M.Sc., "Brewing." Four Lectures.

February 6, 13, 20, 27.

Professor J. A. Fleming, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

March 6, 13, 20, 27.

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

JUVENILE LECTURES.

Wednesday evenings, January 4 and 11, 1911, at 5 o'clock:—

Professor ARTHUR MASON WORTHINGTON, C.B., M.A., F.R.S., "A Study of Splashes, conducted by the aid of Instantaneous Photography." Two Lectures.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 5...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. C. R. Darling, "Industrial Pyrometry." (Lecture III.)

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 6 p.m. Annual General Meeting. Paper on "Sugar Beet."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

British Academy (in the Theatre, Burlington House, W.), 5 p.m. The Very Rev. George Adam Smith, "The Early Poetry of Israel in its Physical and Social Origins." (Lecture II.)

Engineers, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. R. Brown, "The Working of the Road Development Act, 1909."

Chemical Industry (London Section), Burlington House, W., 8 p.m. 1. Mr. Puran Singh, "The Analytical Constants of Shellac, Lac-resin and Lac-wax." 2. Messrs. W. P. Dreaper and A. Wilson, "Theory of Dyeing: Resolution after Treatment with Acids, etc." 3. Mr. A. Kesava Menon, "Some Indian Oils and Fats."

Geographical, Burlington-gardens, W., 8.30 p.m. Mr. J. Howard Reed, "The Geographical Aspects of the Problem of Empire Cotton Growing."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. R. Blomfield, "Pierre Lescot and Jean Goujon."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Oscar Browning, "The Study of History."

Engineers, Cleveland Institute of, Corporation-road, Middleborough, 7.30 p.m. Professor W. A. Bone, "The Present State of Science on Gaseous Explosions."

London Chamber of Commerce, Oxford-court, Cannon-street, E.C., 2.30 p.m. Major E. H. M. Leggett, "Trade Prospects in British East Africa and Uganda."

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Mr. R. A. Leslie Moore, "India and Tariff Reform."

TUESDAY, DECEMBER 6...Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. H. K. G. Bamber's Paper, "Portland Cement, and the Question of its Aeration."

Aeronautical (at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8 p.m. Mr. W. H. Dines, "The Practical Application of Meteorology to Aeronautics."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. W. H. Smith, "Modifications in Platinotype and Recent Improvements."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Mr. C. Herman Senn, "The Cooking of Vegetables."

WEDNESDAY, DECEMBER 7...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. Vaughan Cornish, "The Panama Canal in 1910."

Geological, Burlington House, W., 8 p.m.

Royal Agricultural, Agricultural Hall, Islington, N., 3 p.m. Annual General Meeting.

British Academy (in the Theatre, Burlington House, W.), 5 p.m. The Very Rev. George Adam Smith, "The Early Poetry of Israel in its Physical and Social Origins." (Lecture III.)

Public Analysts (in the Chemical Society's Rooms, Burlington House, W.), 8 p.m. 1. Messrs. Edward Cahen and Harry F. V. Little, "On Fischer's Modification of Volhard's Method for the Estimation of Manganese, and its Comparison with other well-known Methods." 2. Messrs. Edward Russell and T. R. Hodgson, "Note on the Composition of British Wines." 3. Dr. E. Knecht and Mr. E. Hibbert, "A new Volumetric Process for the Estimation of Tungsten." 4. Dr. E. Knecht and Mr. F. W. Atack, "A new Volumetric Process for the Estimation of Molybdenum." 5. Mr. H. Droop Richmond, "The Degree of Accuracy with which the Proteins of Milk can be estimated by the Aldehyde Method." 6. Mr. Edward Hinks, "Note on Gorgonzola Cheese." 7. Dr. E. H. Hankin, "Tests for Cocaine and certain Cocaine Substitutes."

United Service Institution, Whitehall, S.W., 3 p.m. Rev. Dr. Belcher, "The American War of Independence, with special reference to the Expedition from Canada in 1777."

Entomological, 11, Chandos-street, W., 8 p.m.

Royal Archæological (at the Society of Antiquaries, Burlington House, W.), 4.30 p.m. Rev. Dr. J. Charles Cox, "The Assize Rolls and Coroner's Rolls of Yorkshire as illustrating the Abjuration of the Realm by Sanctuary Seekers."

Sanitary Engineers, 120, Victoria-street, S.W., 8 p.m. Mr. G. W. Chilvers, "The Mechanics of Municipal and Sanitary Engineering."

Engineers, Junior Institution of, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. L. W. J. Costello, "Law Relating to Engineering." (Lecture V.)

THURSDAY, DECEMBER 8....Brewing, Institute of, Midland Counties Section, White Horse Hotel, Birmingham, 8 p.m. Mr. J. O'Sullivan, "An Improvement in the Method of Malt Analysis."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Auctioneers, 34, Russell-square, W.C., 7.45 p.m. Mr. W. Bridgman, "Auctioneering in Rhodesia."

London Institution, Finsbury-circus, E.C., 6 p.m Professor Vivian B. Lewes, "Smoke and its Prevention."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. W. S. Routledge, "With a Prehistoric People."

Electrical Engineers, Victoria Embankment, W.C., 8 p.m. Sir R. Hadfield and Professor B. Hopkinson, "The Magnetic Properties of Iron and its Alloys in Intense Fields."

FRIDAY, DECEMBER 9...Illuminating Engineers (at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8 p.m. Professor E. W. Marchant, "Recent Progress in Electric Lighting."

Water Engineers (at the Geological Society, Burlington House, W.), 2 p.m. Discussion on paper by Mr. E. Young Harrison, "The Wellingborough Waterworks and Softening Plant."

Astronomical, Burlington House, 5 p.m.

SATURDAY, DECEMBER 10...Water Engineers (at the Geological Society, Burlington House, W.), 10.30 p.m. 1. Mr. S. C. Chapman, "Gauging and Recording the Flow of Streams." 2. Mr. F. Graham Fairbank, "The Advantages of Co-operation in Rural Water Supplies." 3. Mr. Leslie C. Walker, "The Eliminating Effect of Chlorine on the Bacteria of a River Water."

Journal of the Royal Society of Arts.

No. 3,029. VOL. LIX.

FRIDAY, DECEMBER 9, 1910.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 12th, 8 p.m. (Cantor Lecture.) CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Industrial Pyrometry." (Lecture IV.)

WEDNESDAY, DECEMBER 14th, 8 p.m. (Ordinary Meeting.) REGINALD A. SMITH, B.A., F.S.A., "A New View of Roman London." GEORGE LAURENCE GOMME, F.S.A., will preside.

THURSDAY, DECEMBER 15th, 4.30 p.m. (Indian Section.) ROBERT FELLOWES CHISHOLM, F.R.I.B.A., F.S.A., "The Taj Mahal and its Relation to Indian Architecture." Sir WILLIAM LEE-WARNER, K.C.S.I., will preside.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES ON "INDUSTRIAL PYROMETRY."

On Monday evening, the 5th inst., Mr. CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., delivered the third lecture of his course on "Industrial Pyrometry."

The lectures will be published in the *Journal* during the Christmas recess.

CANTOR LECTURES ON "THE ART AND HISTORY OF BRITISH LEADWORK."

The Cantor Lectures on "The Art and History of British Leadwork," by Mr. Lawrence Weaver, F.S.A., have been reprinted from the *Journal*, and the pamphlets (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John-street, Adelphi, London, W.C.

A full list of the Cantor Lectures which have been published separately, and are still on sale, can also be obtained on application to the Secretary.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 4th and 11th, at 5 o'clock, by ARTHUR MASON WORTHINGTON, C.B., M.A., F.R.S., Professor of Physics in the Royal Naval Engineering College, Devonport, on "A Study of Splashes, conducted by the aid of Instantaneous Photography."

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Members who desire tickets for the course are requested to apply for them at once.

COLONIAL SECTION COMMITTEE.

A meeting of the Committee of the Colonial Section was held on Tuesday afternoon, the 6th inst. Present:—

Lord Blyth (Chairman of the Committee) in the Chair, Sir John Cameron Lamb, C.B., C.M.G. (Chairman of the Council), Byron Brenan, C.M.G., Richard Ernest Brounger, Hon. Sir John A. Cockburn, K.C.M.G., Edward Dent, Hon. Sir Charles W. Fremantle, K.C.B., Robert Kaye Gray, Alexander Siemens, Sir William Hood Treacher, K.C.M.G., with Sir Henry Trueman Wood, Secretary of the Society, and S. Digby, C.I.E., Secretary of the Section.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A Meeting of the Colonial Section was held on Tuesday, November 29th, Admiral Sir Frederick George Denham Bedford, G.C.B., late Governor of Western Australia, presiding.

The paper read was—

THE PROGRESS AND PROSPECTS OF MINING IN WESTERN AUSTRALIA.

By A. Montgomery, M.A., F.G.S.,
State Mining Engineer of Western Australia.

In coming before you to-night it is my pleasing duty first to acknowledge the great indebtedness of the State I have the honour to represent—and of myself personally—to the Royal Society of Arts, in affording this opportunity of addressing an audience in the heart of the Empire on the subject of the mining industry of a member of the Imperial body so distant as Western Australia. It is very appropriate that such a subject should be dealt with before the Royal Society of Arts, for is not mining one of the foundations of all the arts and manufactures, one of the great prime industries at the root of all our commerce, one of the most necessary essentials of our civilisation ? The physical wants and needs of mankind are many, but the provision for all of them rests fundamentally and first of all upon obtaining food and the raw materials of manufactures, and among the latter it takes more than a little reflection before one can realise adequately and fully the enormous importance of the materials which are extracted from the earth by processes of mining. Without metals and minerals civilised life is impossible, and it is as much a necessity of the world's prosperity that the mining industry should be in a healthy and flourishing condition as that the food supplies should be adequately provided for. It is a noteworthy fact that there is no leading nation or state in the world which does not depend very greatly on its mineral resources as the foundation of its strength, our own Empire showing many of the most notable examples. How futile, then, is it to prose about the risky nature of mining as an investment, and to look upon it, sagely, as being of such a nature that no prudent business man will concern himself with it ! Willy-nilly, it will concern him sooner or later if neglected, for it lies beneath all his carefully-reared industrial structures, and can no more be neglected with impunity than the maintenance of the supplies of food or clothing for the population. Both are equally elementary necessities. This view of the position of mining is doubtless a commonplace to many here present, but it is not entirely useless to repeat well-known elementary principles from time to time, and the absolute necessity for the maintenance of an active mining industry as the base of industrial prosperity seems so often to be overlooked that I may, perhaps, be forgiven for insisting on its vital importance.

The State of Western Australia, like all the other States of Australia, has owed its first great advance towards industrial importance to its mineral wealth, its gold discoveries attracting population and providing means whereby the country has been opened up for more permanent settlement. Other industries have followed, greatly encouraged in their inception by the excellent local market afforded by the goldfields, until one frequently hears now more said about the opportunities of settlement upon the lands of the State, and of engaging profitably in pastoral and agricultural pursuits, and in fruit-growing, than of those for mineral development. This is quite in the natural order of things, as has been exemplified previously by California, Victoria, South Australia, and many other countries, and if it were my province to do so here to-night, it would be a pleasure to lay before you some facts as to the immense progress recently made in our State in wheat and fruit-growing, and farming and pastoral pursuits of all sorts, and to point out with all the enthusiasm at my command the excellent opportunities for settlement on the lands of Western Australia which are open to any people of this country who may be desirous of trying their fortune in other lands. That subject, however, I must leave to some of my friends, and confine myself now to consideration of the mining position in the State. But first let me repeat a few general facts about the country, in order to enable those present who may know nothing about it to realise somewhat better the leading conditions under which mining is carried on.

Western Australia is a vast country, justly described as one of "magnificent distances." It

comprises 975,920 (or nearly a million) square miles, and extends over twenty-one degrees of latitude, the north part being within the tropics (in 14° south latitude) and the south approaching the cooler portion of the temperate zone (in 35° south latitude). The climate, therefore, is very different in different parts of the State. There is a good rainfall along most of the west coast, averaging thirty to forty inches annually, but as we go inland it decreases, and on about 57 per cent. of the area of the State the annual rainfall is under ten inches. Sub-arid conditions, therefore, prevail in a large portion of the interior, and provision of permanent supplies of fresh water becomes a first necessity of settlement. In the summer months the shade temperature often rises to over 100°F., and in the tropical parts of the country there is naturally a high average annual temperature, but south of the tropics for the greater part of the year the climate, though warm, is not by any means excessively hot, and in winter it is often quite cold, with occasionally frosts at night. The dryness of the atmosphere enables people to endure a much higher temperature without discomfort than is possible in more humid regions. On the whole, the climate of sub-tropical Western Australia must be regarded as an exceedingly pleasant one, and even within the tropics it has been found that Europeans can live and work with much comfort and excellent health.

There are no high ranges in Western Australia, the altitude of its highest portion being only about 4,000 feet. The greater part of the interior of the country consists of plains 1,000 to 1,500 feet above sea-level, broken by low ridges and island-like low hills. Over the main portion of the central and eastern goldfields there are very few outstanding ranges of hills of any magnitude, but from Peak Hill northwards the country becomes much more hilly, and distinct mountains of some altitude are often visible. In the south of the State also there are some fairly high and steep mountain ridges. There is, however, no great range sufficient to form a source of permanent rivers, and, except in the north-west and south-west regions, where there is a good rainfall, running streams are unknown except during rains. The plains are generally very flat basins dipping towards depressions occupied by salt lakes and saline clay pans. On the edges of these plains there are very often precipitous escarpments ten to fifty or more feet high, known locally as "breakaways," which mark the margins of old lake basins of which the plains were the bottoms. At the top of the escarpments we frequently come on small plateaux, often very level, which are relics of an older marine plain, and on these there are frequently sand dunes, fringing the old lake basins. In the lake-basins the bed-rock is often at a very shallow depth beneath the surface, or even outcropping, but frequently it is covered with detrital material to considerable depths, many wells being sunk seventy to eighty and even over one hundred feet before reaching the bed-rock. It is plain, therefore, that in those old lake basins there has been a great deal of levelling up of old hollows in the bed-rock with detrital materials.

In the districts of the south-west portion of the State, where there is a fairly good rainfall, there are extensive forests of heavy timber, and more inland there are still good timbered belts, which provide excellent firewood and mining timber for the mines. In the Murchison and Mount Margaret districts, however, the heavier eucalyptus timber is replaced by small trees ("mulga"), which supply good firewood and make useful but not first-class mining timber. Still further north the country becomes very open, and is covered with various varieties of grass and spinifex, forming good pastoral country. In these parts of the country it is often very difficult and expensive to procure mining timber and firewood, the trees being confined to narrow belts along the main watercourses. The country is, as a rule, remarkably easy to traverse, there being little or no difficulty, other than that of obtaining water, in taking vehicles over it in any direction without having to make roads. The "bush" is very open, and can often be traversed quite readily in a buggy, or even, in a good many places, in a motor-car. This ease of getting about explains at once the extraordinary way in which the goldfields were overrun by prospectors within the first ten years of the gold discoveries. It also explains why it is possible to lay down railways for not much over £1,500 to £1,800 per mile.

Gold and other minerals are found more or less all over the explored portions of Western Australia, the principal metallic minerals being gold, tin ores, copper ores, lead ores, and iron ores, while coal is the most important non-metallic mineral. The metallic minerals occur in very old igneous and sedimentary rocks, the geological age of which is not yet determined, beyond that it is pretty certain that most of them are older than the Cambrian period. There is a very complex system of exceedingly ancient metamorphic rocks mingled with igneous

intrusives, many of which have become converted into schists, and which may be roughly grouped together as the auriferous greenstones. Breaking through these there are great granitic intrusions, which, in turn, have been pierced by later dykes, both acidic and basic, of different ages. In this great series of old rocks there are doubtless both sedimentary and igneous products of many different ages, the relations of which to one another have not yet been worked out. Lying unconformably on these oldest rocks, we find here and there throughout the country small patches of a younger but still extremely old formation of sedimentary slates and schists (known as the Mosquito Creek series), and apparently of later date than these are the fossiliferous Cambrian beds of the northern part of the State. In the north also we have a large development of Devonian rocks, and in the north and west considerable areas of permo-carboniferous strata. In the most southerly of these last the Collie Collieries have been opened up. The occurrence of patches of cretaceous marine strata and tertiary to recent limestones in widely-separated parts of the State shows that much subsidence and elevation of the country must have gone on since the coal measures were laid down, and numerous physiographical and geological considerations have led me to the conclusion that the country owes the present shape of its surface very greatly to the fact of its having been wholly or in great part submerged beneath the sea within post-tertiary times.

This very incomplete sketch of the geological history of the country may serve to assist in comprehending some of the features met with in mining in it, especially for gold. Except for coal, phosphate rock, gypsum, salt, bauxite, and some few other minerals, and when considering the distribution of alluvial gold and tin ore, we may put to one side, from a mining point of view, all the country occupied by the strata of later date than the Devonian period. In the Devonian system we have a very interesting series of auriferous conglomerates (the Nullagine conglomerates), which are in many respects closely analogous to the "bankets" of South Africa, and it is interesting to note that in these beds the gold is pretty certainly of alluvial origin, derived from the erosion of the underlying Mosquito Creek and auriferous greenstone series, both of which teem with auriferous veins. The Devonian and later strata are comparatively little crumpled by orogenic movements, and show little, if any, evidence of ever being penetrated by mineral veins, and it seems very clear that the period of formation of the mineral veins in the older rocks was long anterior to the Devonian, and probably also to the Cambrian period. All the pre-Cambrian strata, whether igneous or sedimentary, are greatly plicated and contorted, the axes of folding running north-north-westerly in the southern part of the State and north-easterly in the northern, conformably with the general direction of the western coast-line. The complex of ancient intrusive and metamorphic rocks in which the mineral veins occur, and which we now find at surface, were doubtless once deep in the base of a rising region, probably forming a mountain chain like the Swiss Alps or the Cordilleras of South America. There is much reason to regard it as most probable that the quartz veins carrying the gold and minerals were of very deep-seated origin, most of the vein stuff being really more or less sheared country rock transmuted into quartz by metasomatic change. Most probably they are the result of pneumatolytic processes operating—very likely more or less in connection with volcanic activity—during the period of mountain-forming movement, which was certainly mainly pre-Devonian and probably pre-Cambrian.

The principal gold discoveries may be arranged in belts as shown in the map exhibited, which was kindly lent to me by our Government geologist, Mr. A. G. Maitland, F.G.S. These correspond very well in direction with that of the general axes of folding of the oldest strata. It is noteworthy that the main granitic areas have so far been found to contain few mineral veins, and that the latter are usually in the greenstone schists and dioritic intrusives not far from the contacts with the granite. When payable mineral veins have been found in the granite they have in almost all cases been quite close to the greenstone contacts. Many of these contacts have probably been lines of very severe faulting movement, the greenstones along the contact being very much sheared and foliated, and the granite being also in some cases converted into schist, which a short distance away soon merges into gneiss and granite. Some of these shear zones along the granite contacts are of great length and persistency, one passing through Southern Cross, for example, being traceable for over sixty miles at least, and they are very notable as containing several important mines, and very numerous smaller auriferous veins.

The official records of mineral exports from Western Australia commence in 1850, when a

small quantity of lead ore was exported from the Northampton mineral field, and three years later a small amount of copper ore is found among the exports. Ores of these metals continued to be the principal mineral production for many years, copper mining at Northampton reaching its zenith in 1864 and lead mining in 1877. Exports of gold are first recorded from Kimberley in 1886, followed by Pilbara and Yilgarn in 1889; Ashburton and Murchison in 1891; Dundas in 1893; Coolgardie in 1894; North Coolgardie, North-east Coolgardie and East Coolgardie in 1896; Peak Hill, Yalgoo, East Murchison, Mount Margaret, and Broad Arrow in 1897; Gascoyne and Donnybrook in 1899; and Phillips River in 1902. Exports of tin ore from the Greenbushes mineral field first appear in 1889, and from Pilbara in 1893. Coal is shown for the first time in 1898; mica in 1892; while sundry other minerals, including asbestos, cobalt ore, plumbago, antimony ore, tantalite, scheelite, and wolfram appear in and after 1900.

To avoid loading my address with figures which could not be kept in mind if simply read over to you, printed slips have been distributed, with a number of tables and other figures showing leading facts about Western Australia's mining industry. These are now printed as an Appendix (see pp. 82–89).

Table No. 1 shows the mineral production of the State to end of 1909, as set forth in the returns of gold received at the Royal Mint in Perth, and the export values of gold and minerals sent out of the country. Except for a certain amount of specie and manufactured gold retained in the State, practically the whole of the minerals produced are exported with the exception of coal, limestone and ironstone. In the table the production of these latter minerals as returned by the producers is shown alongside the exports, and the difference—being the local consumption—added to the total of exports, should approximately represent the total production, which is thus seen to amount to a value of, roundly, £95,000,000, to the end of 1909.

Another very similar table is also published in the annual statistical returns of the Mining Department of the State, showing the figures of production as returned monthly by the producers, but these come out with a somewhat lower total than the export figures, though agreeing in broad general features. Mine-owners have not always been as careful as they should have been in having their production properly recorded, the total being slightly under £90,000,000 sterling to end of 1909 (£89,494,650). In both estimations there is doubtless a considerable amount of gold omitted which has been taken away by alluvial diggers and others leaving the State, especially in the earlier days.

It may be seen from the table that, out of a mineral production valued roundly at £95,000,000, about £92,000,000 have been due to gold; tin and copper ore only approaching their first £1,000,000 in value, while the advance in the annual production of coal, especially for export, is very noteworthy.

In order to show the position of the State of Western Australia as a gold-producer, I would now ask you to look at two of the tables, Nos. 2 and 3, taken from the last Year-Book of the Commonwealth of Australia, showing the world's production of gold from 1897 to 1908, and also at No. 4 from the same authority, showing the individual production of the various States of the Commonwealth. It will be seen that Australia's contribution is the vast sum of £501,474,700, and that its annual production, though still very considerable, has fallen in relative importance from 26·36 per cent. in 1900 to 14·28 per cent. in 1908, but also that this is due not to the falling off in Australia's output as much as to the immense advances in production in Africa and North America, particularly the former, where the output has been more than doubled in the last five years of the table. Among the States of Australia, Western Australia easily holds the lead in annual gold production since 1897, and, though her total output is still far below the huge sum contributed to the world's stocks by Victoria, it now exceeds that of any of the other older gold producers of Australia.

Taking other minerals as well as gold, Table No. 5 shows the total mineral production of Australasia, including New Zealand, and it will be seen that Western Australia and New South Wales are running a close race for the leading position. Another rather striking feature of the table is that it shows that there has been an almost universal decline in production in all the States of Australasia during the years 1908 and 1909, New Zealand being the only one in which the output for 1909 exceeded that of 1907. The average annual production for the eight years tabulated is in all cases, except New South Wales, greater than the 1909 output.

Let us see how mining stands statistically as regards other Australian industries. Here, again, we find a useful table in the Commonwealth

Year-Book, which is quoted (No. 6) among those in your hands. It will be seen that the value of mineral production is nearly 15 per cent. of the grand total for the whole of Australia, and in Western Australia in 1908 was nearly 50 per cent. The importance of the mineral industry to Western Australia is even more strikingly shown by Table No. 7, showing the proportion of its own mineral exports (other than coal) to its total exports. For the last ten years the average proportion is seen to be no less than 78·9 per cent., and in 1903, the year of greatest gold production, it was as high as 84½ per cent. For the last five years the ratio has been steadily falling, not only on account of a decline in mineral production, but also on account of a very gratifying advance in the production of agricultural and pastoral produce, but in 1909 it still was two-thirds of the total.

The aspect of the matter, however, which is the main concern of the British investor, is naturally that of the value of Western Australian mines from a stockholder's point of view, and here we come in contact with many considerations which tend to obscure the fundamental issues. The market value of mining shares depends on popular estimation from time to time, and fluctuations in value by no means necessarily indicate the true position of affairs at the mine. Many people make and lose money by dealing in mining companies' shares, and put their gains, and more especially their losses, down to "mining" when they are simply due to share-dealing. One may buy stock in a mine which is making very profitable returns at so high a figure that the dividends give a very inadequate interest upon the investment, but in such a case it is not the mine which is at fault, but the investor's own judgment. To try and get at some of the leading facts of the case from a purely industrial point of view, let us look at Table No. 8, showing the amount of dividends paid by Western Australian gold-mining companies in comparison with the total production. It will be seen that the average return has been 22·1 per cent. of the total produce, and that the dividends have ranged from 18 per cent. to 26·1 per cent. of the total production, which is a very favourable showing for any industry. As, however, this way of looking at the question shows only the percentage of the total production paid in dividends to registered companies, and leaves out of account a large number of small mines privately owned, many of which are very profitable, the last two columns have been added to the table to show the ratio of the dividends to the value of the gold produced by the registered companies alone for the last three years, and it is seen that the dividends have amounted to an average of 27·6 per cent. of the total production of all the registered companies. The very profitable nature of the gold-mining industry is very well shown in another way by stating that the average value of gold produced per man employed, both on surface and underground, was £444 in 1908 and £413 in 1909.

Taking another basis, I find from Table No. 7 in the annual report of the Mines Department for 1909 that dividends were paid by twenty gold-mining companies, the total share issues of which amounted to 6,961,663 shares paid up to £6,913,560 10*s*. Their dividends for 1909 were £1,359,115, equal to an average of 19·7 per cent. of the paid-up capital. This is surely a very profitable return on the money invested in these companies. I regret that I have not been able to get hold of any reliable estimate of the total capital contributed by companies towards exploiting the mines of Western Australia, and it would be still more difficult to arrive at any true valuation of the amount of cash actually spent in the country—which is the true industrial basis upon which the proportion of dividends should be calculated. The twenty mines referred to are, however, the largest and most important in the State, and it is improbable that the actual expenditure from capital in the case of the other non-paying and extinct companies has greatly, if at all, exceeded the £7,000,000 spent in the equipment and development of the large producers. The total amount of dividends paid, say, £20,000,000, must be now very greatly in excess of the total cash laid out by the investors from capital in *bona fide* mining operations. I am not speaking of the return on the nominal capital of the many companies which have failed in the State in the past, as calculations on that basis seem to me to belong to the province of share-dealing, and not to mining as an industrial process, and in claiming that the Western Australian mining industry has been a highly payable one on the whole to those who have invested in it, I rest my case on the fact that far more money has already been repaid to the investors in dividends than they have laid out from capital in opening, equipping and exploiting the mines.

When one considers these very favourable results, it is somewhat difficult to understand

the adverse attitude which has prevailed in the London mining market for some years past towards Western Australian mining ventures. There is no question but that they have been greatly out of popular favour for some years past, and there seems to be a very general feeling among investors in England of great distrust of the country and disinclination even to listen to representations in its favour. One reason of this was, no doubt, the multitude of unsuccessful West Australian mining companies which were floated in the earlier days of our goldfields, from ten to fifteen years ago, through which the investing public suffered heavily. In regard to these, nevertheless, it is only just that a careful distinction be made between the losses made in stock-dealing and the actual losses on mining work. In very many cases it will, I think, be found that the heaviest portion of the losses of the shareholders was the money paid to promoters and others in forming the companies and in their own market dealings in the shares. Frequently many causes co-operated to make the ventures unsuccessful, and it is by no means either fair or reasonable to jump to the conclusion that because a mine proved unsuccessful it was necessarily an obvious "wild cat" from the inception. That there were some frauds deliberately put upon the market is likely enough, as has been the experience in every mining "boom" in every other part of the world as well, but it is rather surprising to find what a large number of cases there are in which mines opened by companies some years ago and abandoned by them as unpayable have been since worked profitably. Very many of the so-called "wild cats" were guilty of nothing worse than being prospects greatly over-rated by their discoverers and promoters, and the public who rushed to invest in them without sufficient examination were almost as much to blame for their lack of ordinary and reasonable caution as were the promoters who offered them the bait. This sort of thing happens in all "booms" more or less, and seems quite inseparable from mining-company promotion as the world is at present constituted. Many of the ventures were entirely premature, the grade of ore in the mines being unworkable profitably at the time they were taken up, though since then, under better conditions, it has been possible to re-open several of them to advantage; many were failures due to want of experience of ore deposits with the peculiar local features presented by the lodes of the West Australian fields—some were very badly managed, and some with brilliant surface prospects, as they were opened, became too poor to be followed up. It is in the nature of mining that there can be no certainty as to values in ground which has not been well proved by systematic development, and when undeveloped "prospects" are undertaken there is necessarily much risk that they may turn out badly rather than well. When an unproved property is taken in hand for mining purposes it is always well for the investors to have their minds made up that the risks of disappointment are very great, and to be prepared to follow a policy of first proving their ground well before launching out into much expenditure on plant and permanent development. It will often, in such cases, be found advisable to do a good deal of work upon quite a number of promising "prospects" before settling down in permanent fashion upon one or more of them. In the earlier days of the Western Australian boom—as in all similar cases—this elementary precaution was quite overlooked, and investors rushed madly to pay large sums for ground on which practically nothing had been proved and the value of which no man living could predict. The country is full of lodes and mines carrying more or less gold, and worth more or less prospecting, and in most cases when gold has been found in the outcrop it is quite impossible for any one to predict with any certainty whether the lode below it is going to be a good one or not. Many very promising-looking outcrops have proved very disappointing when sunk upon, and conversely poor surface indications have frequently been found to cover excellent values in depth. No one can tell how they will turn out without a good deal of development, and in the early days this was almost entirely overlooked, and investors found themselves committed to the working of reefs for which they had paid high prices, but which they would not have undertaken seriously if they had done some preliminary work upon them before completing their purchase. In such circumstances it is very natural that the owners should persevere with undertakings that would be much better left alone after the first preliminary workings have shown that the prospects were not so good as anticipated, and much money has been uselessly expended through a creditable but mistaken notion of pluck. The owners find themselves committed to a venture and determine to see it through, for better or worse. Many good mines have been found by such perseverance, and in many aspects it is highly commendable; but investors should take such risks with their eyes

open and not give way to excessive disappointment if their efforts result in failure instead of success.

Since the earlier days a great deal of valuable knowledge has been obtained as to the behaviour of the lodes of Western Australia which was not well understood at first, and there is not much fear now that the mistakes of former days will be repeated by any careful and experienced manager. Purchasers now very properly demand time to satisfy themselves thoroughly about the prospects of the properties offered to them, and do not usually complete their bargain until they have themselves developed the mines to some extent on an option of purchase. Many reefs are often thus examined before a purchase is finally completed, and the industry is put on a far sounder basis in consequence.

At this stage I must digress a little to meet a comment which is often made, and which on the face of it seems very reasonable. We are told that the British investor does not want to trouble himself with prospecting risks, but would rather put his money into concerns which have been well proved but require capital for equipment with machinery for ore treatment and further mining development. Let the local people do the prospecting and proving of the lodes, we are told, and then capital will come in freely for any genuinely good concern. This sounds very sensible, but is in truth very impracticable. It is a sort of academic platitude, quite unsuitable for practical workaday conditions. First of all, who is going to do the preliminary proving of the mines? The prospectors cannot do so as a rule themselves, being usually poor men who have to earn a living while they are doing the necessary development, and unless they have backers to find them in food and stores they cannot go on. As a matter of fact, the local residents of the goldfields, especially those in trade and business in the goldfields centres, do a great deal of backing of prospectors, but a few figures will show the magnitude of their task in Western Australia. The population of the State is now about 285,000 persons, counting men, women, and children. The area of the proclaimed goldfields is 330,126 square miles, or more than a square mile to each person in the State. The leases held in 1909 were 2,105 in number, comprising 28,919 acres, or a little over an acre to every ten persons, and this year there were also 12,465 acres held as prospecting areas as well. The mineral-bearing country extends from north to south right across the continent of Australia for over 1,300 miles. In all the mining districts there are dozens of lodes known for every one which has been tried at all seriously, and many of these lodes and veins might yet be found worth working. We are, besides, finding new ones every day as prospecting proceeds, not only in new country but also in the oldest and most worked of the fields. The multitude of lodes on which prospecting is worth doing is quite astonishing, and cannot be realised without travelling through several of the mining districts and examining them somewhat minutely. It then becomes manifest that there are still enormous opportunities for good mining discoveries, and that active and systematic prospecting can hardly fail of being sooner or later well rewarded. Instead of the fields being worked out, as some people imagine, it is seen that they have barely been begun upon, and that there must still be vast mineral wealth to reward well-directed prospecting. An excellent illustration of how little thoroughly the country has been prospected is afforded by the recent discovery of two mines, which promise to become very important, in the Southern Cross auriferous belt, the oldest of the discoveries in the eastern goldfields. One of these is only about seven miles from the original discovery at Golden Valley of gold in the eastern field. Further south, on the same belt, a large and valuable lode has been found close alongside a mine which has been working for years. Very many similar instances could be quoted.

One good reason, therefore, why the local residents do not themselves do the preliminary work of prospecting before inviting capital to come to their assistance in mining development, is that they are doing all they can already, and that the field is far too vast for the means of a small population. At the same time great attention is being paid to opening up the land of the State, and great numbers of people who might otherwise have money available for mining have their hands quite full in fencing, improving, and stocking the virgin country which they have taken up. For their numbers and means it will be found that the people of Western Australia are quite as enterprising in mining ventures as any of their neighbours, and are doing all they can, but they can only do but little in such a vast field. For every man now engaged in mining, I am convinced that the fields could easily support ten if they were adequately developed, but both population and capital are required before this can be brought about. There are great opportunities waiting to be

seized, for both capital and labour, in developing these fields. One is of no use without the other, nor either without what has been well termed the third leg, which gives stability to the industrial stool—brains and knowledge. But if capital and labour can be made to work together under intelligent and skilled organisation there is no doubt whatever that the conjunction of effort would result most satisfactorily in a field of such great potentialities as the Western Australian goldfields.

Reverting to the argument that the British investor should not concern himself with prospecting ventures, but wait till fairly well-proved mines are put before him, there is another fairly strong reason why such a policy is not the entirely admirable one it is often represented to be, and that is that the best of such concerns are apt not to come on the market at all, or only at a very high price. Why should the men who have found and proved a really good mine part with it unless at a very good price? Once large values are proved to be in sight they can usually continue to get enough money in one way or another to procure plant to enable them to realise the more easily-obtained wealth in the ground, and the mine itself then soon provides funds for further equipment. Many of the best mines in the world have thus been opened with very little assistance from outside capital, and when such mines do require large additional capital for new and heavy equipment they are usually in a position to exact very good terms for themselves. The question for an investor to consider is whether it is really his best policy to spend thousands in acquiring an interest in an already proved concern in which he can count on fairly certain profits, or to spread his risks in small sums over a large number of prospecting concerns, the success of one of which would fully compensate him for losses in all the others. I do not think it can be held to be at all well demonstrated that the former apparently safer course has, as a matter of experience, been proved to be more generally remunerative than the latter bolder and more speculative one, in which the fruits of the discovery of a good mine are preserved to the adventurers. It is very noticeable that practical mining men are usually themselves keen supporters of prospecting, risking their money to find new mines rather than investing it in going concerns, and, while this may be regarded as gambling, I am not at all sure that it is not really more properly to be recognised as the result of their intimate knowledge of the actual facts of the industry, and that they are not quite right in adopting the apparently more risky course. Search for new discoveries is a speculative venture, but it is one of the most essential factors of the industry, without which its decline and fall are inevitable; and when it involves a necessary expense and risk that are inherent in the nature of the business, it is not fair to denounce as gamblers those who prefer to undertake it rather than the less speculative work of developing the discoveries made by others. They are undertaking a very necessary part of the work, without which it cannot go on.

Of late years in Western Australia a good deal of exploration work of this nature has been done by several of the existing mining companies, with a view to providing new mines to replace their own when they may become worked out. The usual course has been for them to examine what are represented to them as promising discoveries, and if satisfied with the preliminary tests to arrange terms on which they may obtain an option of purchase over the property for a stated time, during which they undertake to do a certain amount of development work. When they have done this work they are in a position to see if the mine is worth buying or not, and can act accordingly. Many properties have usually to be examined in this way, and a good deal of money spent on them, before one quite satisfactory is found of which the purchase may be completed, and in some cases large sums of money have thus been expended without getting hold of any good mine. Several companies, however, have no reason to complain, and have been able to acquire very valuable properties. One recent good example is that of a company which is said to have expended some £50,000 to £60,000 in testing properties, but has been able to acquire as a result no less than four very promising mines which seem likely to give them good profits. As the work of selection of mines is now conducted, it is on a very business-like basis, and there is no more of the speculative and reckless purchase of unproved ground that led to so much loss in the "boom" days.

There is still a great field open for further development on the same lines, particularly if the companies undertaking such work will not despise mines of less than first-class magnitude. Hitherto the search has been mainly for lodes big enough and good enough to be worked on a fairly large scale by a single company, with mills of twenty or more heads of stamps. But such mines are very much less common than

smaller ones, which can be worked profitably with a ten-head mill or even, sometimes, with only five stamps in the case of somewhat small yet rich veins. A large number of such mines are being worked throughout the State, mostly by single local owners or small parties, who have contrived to get some machinery together, often very inadequate for cheap handling of the material, and are conducting all the operations themselves. Many of them have been successful —some very much so; but there are also very numerous instances where these mines might do very well were they not crippled by want of means. With an expenditure in plant and development of, say, £3,000 to £6,000 they could often be put in a position to go on steadily as profitable concerns, and their profits, though perhaps not great individually, would give very excellent interest on the money expended upon them. A surplus of £1,000 annually on the work of such small mines is not a great deal, but it would be 20 per cent. on an investment of £5,000 in equipping them, and even small mines when profitable at all often return far more profit than this. There seems to me to be an excellent opening for exploration companies which would take over a number of such smaller mines as well as any of the larger ones they can get, and would work them in conjunction with one another, one superintendent having general supervision of the whole of the operations and concentrating all possible office work in his own office, with only good foremen managers on the mines. Small profits from a number of individual mines would then amount to an appreciable sum in the aggregate, well worth the consideration of a fairly large company. Such a scheme is more broadly based and affords better chances of success on the average working than when the company is tied to one particular mine. It also offers advantages in the matter of allowing of transfer of plant from a property which proves a failure to some other held by the same company, without the sacrifices which invariably attend the disposal of the machinery of a mine which is given up.

While on this part of the subject it will be of interest to look over Table No. 9, the results shown in which have been worked out from the annual statistics of the Mines Department. Here we see the relative numbers for the last three years of the principal companies, which had an annual output of over 12,000 ozs., or, say, over £50,000 roughly, compared with the smaller companies and private producers making returns of a smaller amount per annum, and also the goldfields in which they are situated. Returns are shown from 166 companies in 1907, 149 in 1908, and 153 in 1909, and from 879,841, and 883 other owners in the same three years respectively. While eighteen, twenty-three, and twenty-three of the companies, produced over 12,000 ozs. per annum, the number producing over 5,000 ozs. rises to forty, forty, and forty-two in the three years. The third part of the table then shows the number of mines which individually produced over 1,000 ozs. in each of these years. Incidentally it will be seen from the second part of the table that in the more important mines the tonnage crushed has increased from year to year, although the total output of gold has diminished. This is due not altogether to falling off in the value of the ore, but greatly also to improvements in mining and milling methods, which have enabled ores lower in grade than formerly to be dealt with profitably. For example, if mining and milling costs come to nearly £4 per ton, it is clear that the ore must return an ounce or more of gold in order to yield a profit, and poorer ore is best left unbroken in the mine; but if the costs are reduced to, say, 30*s*. a ton, then 8 dwt. rock can be utilised with profit, and the reserves of ore become greatly increased. So long as there is a margin of profit on the lowest grade ore mined it is usually better policy to take it all out with the richer ore than to work out the latter by itself and then return for the poorer stuff. It is often not possible to get back to the poorer ore afterwards without much cost. The increase in the tonnage and fall in the value shown in the table is in this regard, therefore, rather an indication of strength in the mining position than the reverse. For the last ten years mining and treatment costs have been improved from year to year very steadily, until now some very low figures are shown by various companies, notwithstanding high costs of labour, and in some of the most notable cases long distance from railway communication as well.

The table also, it seems to me, indicates much vitality in the mining industry in regard to the smaller mines. It is from these that we must expect the list of the more important mines to be recruited from time to time. It is in the nature of the case that active mines must become worked out sooner or later, as there is no replacement of the ore removed, and consequently we must expect the larger mines after a longer or shorter period of production to fall off in their returns, and one after another to drop into obscurity. But if there are plenty of others

behind them to take their places there is no fear of the extinction of the industry. There seems to be a very general but much mistaken belief among the public that the day of Western Australia is over as regards mining, and that this industry must be expected soon to dwindle away to unimportance. The yearly drop in the production since 1903 is pointed out as proving this contention, quite irrespective of any consideration of the causes of the decline. When we look more into the details of the decline we find that it is largely due to the falling off in yield of a few of the largest mines and of several of the older smaller ones, which have first had several years' successful running. For example, the yield of the Great Fingall Mine fell from 99,253 fine ozs. in 1907 to 81,585 in 1908, and 41,269 in 1909; that of the Westralia Mount Morgans from 38,358 fine ozs. in 1904 to 14,993 in 1909, and that of the Great Boulder Perseverance (owing to a disastrous fire in the mill) from 70,681 fine ozs. in 1909 to very little at all in the first half of the present year.

Several districts have shown substantial increases from year to year. For example:—Black Range from 57,633 fine ozs. in 1907 to 72,388 in 1908, and 76,797 in 1909; Nannine from 31,357 ozs. in 1907 to 37,209 in 1908, and 49,953 in 1909; and Dundas from 23,449 ozs. in 1907 to 27,918 in 1908, and 27,935 in 1909. On the whole, however, the decreases in yield for the last seven years have exceeded the increases, and the production has, therefore, fallen off. Nevertheless, as Table No. 9 shows, there was a decided advance in 1909 in the production of the privately-owned leases over that of 1908, and it will be seen also that the number of mines making returns was larger than in either 1908 or 1907. The number of men engaged in mining was also larger than in 1908, giving some grounds for thinking that there are signs that the ebb in production may soon give way to an again advancing tide. What is most wanted to stimulate production is a more liberal investment of capital in searching for and opening up new mines, to make it worth while for prospectors to set to work again actively, to enable new large mines to be found, and particularly to organise and equip the smaller ones which are already known, so as to make them effectively productive. Everything points to money well laid out in such work reaping a very productive harvest.

The 883 small mines not held by registered companies produced in 1909 nearly £1,100,000 worth of gold, or a little over an average of £1,200 apiece. It is a very conspicuous feature of Western Australian mining, and one which counts very strongly in its favour, that there is such a large number of small parties of men working their own mines in a small way and making a living—and often very good profits as well—out of the ground by their own labour. So long as they are in the softer superficial country above the water level they can generally work without machinery at all, provided they are within accessible distance of a battery to which they can cart their quartz for treatment. In some respects this facility is really detrimental, for men take out the easily-got ore from near surface and then pass on to another reef, and in a few years the old workings become inaccessible. There is before me a little book published by our Mines Department showing a very long list of leases, 2,268 in all, which have become cancelled, and were in March, 1910, open for anyone to select. Many of them, however, are the same, or nearly the same, ground taken up two or three times over, first by one party then by another. The aggregate yield from these leases is a very large amount, every lease on the list having a recorded output of gold. I doubt if there is any place in the world which offers the man anxious to get a small mine of his own a better chance than Western Australia, for there is any amount of ground open for prospecting, and in most of the older districts there are facilities for crushing the ore within reasonable distance. Cartage is easy, almost anywhere, without having to spend much money in making and clearing roads. Many men, therefore, have made a very good living at working mines for themselves, and quite a number have made fortunes, without ever approaching the market. A prominent instance recently is that of the Fenian Mine at Meekatharra, owned by four men. It is opened up to a depth of 625 feet, has its own battery, cyanide plant, and winding machinery, and when I left the State was putting up new plant out of revenue. It has paid £77,000 in dividends, and the lucky owners were said to be getting dividends of £2,000 a month. Few have been so successful as this, but many other working parties have done very well. Very many such parties are now getting a fair amount of plant upon their mines and settling down to steady work, though very often better organisation and management than their own would make the mines far more profitable, the parties being often anything but good business men.

and frequently very indifferently skilled as miners. When a mine gets to the stage of being systematically worked with the aid of machinery, it is probably best in the majority of cases that it should be handled by a company under a skilled mining manager and not by private owners.

As we have now seen that there is nothing in the reproach that the people of Western Australia are themselves inactive in opening up their mines, let us examine another objection which is constantly being brought forward as a reason why the British investor should pass Australia by and put his money into foreign countries, namely, the alleged fact that the conditions of tenure of mining property are very onerous and unsatisfactory in the former. When one asks for instances and specific complaints, it is very soon found that the statement is based on misconceptions and misunderstandings of the true position made by people who do not understand—and often appear not to want to understand—the facts of the case. It would take far too long now to make a comparison of the terms offered to investors in mining properties by the various countries which are inviting the aid of British and European capital, but when the matter is closely gone into, any unbiassed investigator soon finds that there are few, if any, countries—personally, I have not been able to find any—which give terms more favourable to the investor than Western Australia. The whole tendency of recent legislation has been to make them still more favourable, it being thoroughly well recognised by all responsible political parties in the State that outside capital is required for active development of mining, and that good terms must be offered to attract it. Most of the complaints which have come within my own official knowledge have come from persons who have been trying to secure concessions and advantages to which they were not entitled, and who in many cases have been trying to evade their own performance of the obligations into which they entered when they undertook to work the mines. Such people often make a great outcry and present a fair-seeming *ex parte* case, but their statements should not be accepted as gospel until the other side has been heard in reply.

In 1907 and 1908 an investigation of the mining laws of Australia and New Zealand was carried out by a Special Commissioner, Mr. A. C. Veatch, sent from the United States Geological Survey at the instance of an Investigating Committee of Congress, whose report has been issued in Bulletin form by the Washington Government Printing Office. This gentleman speaks very highly of the mining laws of the Commonwealth, and is especially complimentary to those of Western Australia. He strongly favours the leasehold tenure obtaining there rather than the freehold one of the United States, and concludes by saying that:—"In short, viewed from the standpoint of present-day knowledge, the Western Australian mining law has proved a decided success." He elsewhere describes it as a "wonderfully symmetrical and carefully-balanced enactment," which as recently as 1904 has been revised "to meet the practical workaday conditions of a mining region."

Many of the objections urged against the mining laws of Australia arise from confusion of ideas as to the principles adopted by various countries. A person accustomed to freehold tenure is apt to misunderstand the laws of another country wherein, as in Australia, only a lease is granted of mineral ground, and the fee-simple is reserved to the State. There is much to be said for both principles of tenure, each having its own advantages and disadvantages, but, from the point of view of practical mining business, there does not seem to be much to choose between them so long as a mine is in active operation. It is when a man wishes to hold ground locked up for speculative purposes, or sometimes for protection of previous expenditure, that the freehold becomes most desirable; but for all working purposes the matter usually in practice is one of indifference, there being rarely any difficulty under the leasehold system in obtaining all reasonable protection of any owners' interests.

Objections are often raised in quibbling fashion to the powers left in the hands of the administration of the mining laws to decide when concessions may be made to leaseholders in such matters as total or partial exemption from working their ground for a time, terms on which labour may be concentrated on one portion of a holding, and similar matters, it being complained that the investor is too much at the mercy of the Government of the day. There is very little force in this argument. Most of the conditions governing such cases are, as far as possible, clearly prescribed by law, and, therefore, fixed and open to the knowledge of everybody, and where discretion is left to the administration, it is nearly always to meet the cases where special circumstances may require

special treatment, and the decision cannot be made by hard-and-fast rules, but must be left to the discretion of some person. Such cases are inevitable and protean, as in all other sorts of business. In dealing with people of one's own blood and language, one can surely look for reasonable consideration of questions in which both parties are jointly interested, and just treatment from local authority. Fears as to ultra-democratic legislation are on much the same footing; after all, the people in the colonies are very much like those in the parent country, with similar notions of fair dealing and justice, and no more to be feared than their relatives in the United Kingdom. As a matter of fact, no Government of any party in any Australian State has ever yet refused to consider reasonable representations of investors and to meet them in a reasonable spirit, and in a world of business it is surely clear that fair dealing all round must be the basis of conduct, no matter what party may occupy the seats of Government.

When trying to find out lately what it was that the London market has against Western Australia, I was rather surprised to find that a great complaint was that the Government did nothing to encourage investors to go there, and was asked what did we do to encourage any person to attempt to open mines in our State. Well, a great deal has been done and is being done towards that end. First of all, as just explained, we offer exceptionally favourable terms on which to acquire mining properties, and follow British principles of law, justice, and procedure in settling all disputes. If we offer good propositions, what more can anyone want than a thoroughly fair chance of trying them, and a fair run for his money under the conditions which exist when he undertakes the venture? But the Western Australian Government is all the time improving these conditions, as far as it is able, by spending large sums annually in building railways, establishing mail and telegraph services and other business facilities, providing water supplies, establishing State batteries at which preliminary trials may be made, assisting in diamond drilling, and even by direct monetary grants in some cases. The question is not what do they do to assist the investor, but what do they not do that is reasonable and feasible? The railway system comprised to June 30th, 1910, no less than 2,145 miles of line, costing £11,384,000 for construction and equipment, and is being constantly extended. During 1907–8, 102 miles of new line were opened, the next year 101 miles, and last year 100 miles. Since last June the railway to Black Range has been opened, also one from Nannine to Meekatharra, and three others are expected to be opened before the end of the financial year in June next. Others are projected, and on some of them work has been already begun, as in the case of the line from Port Hedland to Marble Bar, to open up the Pilbara goldfield. These lately-undertaken railways are practically all for developmental purposes; they have not been made because it was a payable business to do so, but in advance of settlement and development, in order to improve transportation so much that development could be greatly extended. Take, for example, the Port Hedland to Marble Bar railway. It would be idle to expect it to pay its way if the amount of work done in the district opened by it and the number of people in it were to remain as at present. But it is believed that the district is a good one and capable of great expansion of mining and population, if its present inaccessibility is removed, and there has been little hesitation in authorising the construction of the line once Parliament was convinced that this was the case. In the same way agricultural railways are being run out into nearly virgin country, to enable settlement to go on. Of course it is essential that as far as possible such work should be made immediately reproductive to try to cover working expenses and at least part of the interest bill, and while the volume of business is small, it is clear that somewhat high rates of freight may have to be charged. From time to time they are reduced as it becomes practicable to do so.

So also with water supply. The great pipe line, 351 miles long, which supplies the Kalgoorlie mines with water from near the coast, has cost £3,236,232, and though working expenses amount to only about 1*s.* 6*d.* per 1,000 gallons, averaging the whole system, interest and redemption bring the actual cost of the water sold last year to an average of 7*s.* 7*d.* per 1,000 gallons, and the full cost on the goldfields is estimated at 9*s.* 1½*d.* per 1,000 gallons. Water is sold to the mines at prices of from 4*s.* 9*d.* at Southern Cross to 8*s.* 6*d.* at Bulong per 1,000 gallons, where use is made of no other source of supply, the large mines at Kalgoorlie paying 7*s.* per 1,000 gallons, and a concession being made to poor mines by letting them have it at from 3*s.* 6*d.* to 5*s.* per 1,000 gallons. It is all very fine to grumble at the high rates of freight paid on some of the railways and the high cost

of water, but surely the Government have conferred a great benefit in making the services available, even at these so-called high rates. They are far lower than those previously prevailing when there was no railway and no pipe-line. Plainly, the Government have given immense assistance to mining by its railways and water-supply expenditure, and while these services are not yet making profits which would be considered commercially satisfactory, and are in many cases hardly, if at all, paying actual working expenses, it is surely somewhat ungrateful and ungracious to demand still further concessions from the Government.

Besides the Coolgardie water scheme, there is large Government expenditure in making and maintaining wells and tanks throughout the State, and all the main roadways are now fairly well provided with water. Boring parties are at once sent out to every new field which promises at all well, to try to find fresh water and battery-water supplies. The costs of established water stations during 1908, including interest and redemption, were £19,879, and the revenue was £12,634. The assistance given by the Government to mining in undertaking the water supplies is incalculably valuable.

The assistance given by the State battery system does not appeal so much to an investor in public companies as to the man who is trying to open a mine by his own work. To such they have been an inestimable boon, enabling them to pay their way out of the stone which they raise. During 1909 there were thirty-five batteries in operation, containing 294 stamps capable of crushing 300,000 tons of ore per annum, but, as they were not kept fully employed, only 94,218 tons were actually crushed. Most of these batteries have cyanide vats for leaching treatment of the tailings, and some have been equipped with slimes treatment plant as well. From the inception of the system to end of 1909 the State batteries have cost £275,320, and have crushed 695,129 tons of gold ore, averaging a yield of 1·04 ozs. of unrefined gold per ton, for a return of £2,658,966. They have also treated 449,492 tons of tailings (sands and slimes) for a return of £42,192, bringing the total value of gold extracted to £2,701,158. The tonnage is mostly in small parcels, the batteries in 1909 treating, for example, 1,741 separate lots, or an average of fifty-four tons per lot. From its inception to the end of 1909 the loss on the State battery system is stated as £105,411, or, including depreciation, £257,787. Though this is a large sum for the Government to have spent to assist in the opening up of the fields, it has, without doubt, been more remunerative than the figures would indicate, for the existence of the State mills has been the means of keeping many districts alive that would otherwise have been abandoned, and has so developed others—such as Black Range, Meekatharra, and others—that they have reached the stage when many of the mines have mills of their own, and some of them have been taken over by public companies.

Besides the State batteries, owned and worked directly by the Mines Department, there are many privately-owned batteries throughout the State which receive subsidies from the Government to induce them to throw their doors open for crushing for the public. During 1909 there were twenty-nine such batteries subsidised, which crushed 30,767 tons of ore. The average rate of subsidy was 1*s.* 5½*d.* per ton, the rates varying greatly according to locality. This represented direct assistance from the Treasury of £2,207.

Under the Mining Development Act loans, at a rate not exceeding £1 for £1 of their own expenditure, are made to parties working mines to assist them in developing their mines and equipping them with machinery, the loans being repayable if the mine proves successful, and being secured by mortgages upon the mine and plant. Advances on similar but somewhat less stringent terms may also be made to persons putting up mills for public crushing purposes. Money may also be advanced on loan for boring with diamond and other drills, or may be expended by the Government on its own account, and subsidies are often granted to people who have to cart trial parcels of ore long distances, and also to prospecting parties which are developing their mines below a depth of 100 feet from the surface. Assistance is also given to prospectors in approved cases by providing them with Government camels, or horses and carts, to enable them to open up new country. The total expenditure for 1909 for these purposes was £13,896, and refunds were obtained to the amount of £2,430. The principal and accrued interest on outstanding loans at the end of 1909 was £28,479, and £11,976 had been written off as irrecoverable.

The aid of scientific investigation of the mines and mineral fields is not overlooked either, for an active geological survey is maintained, and also a well-equipped school of mines, both involving large annual expense.

In fact, all along the policy of the Western Australian Government has been to encourage mining by every means in its power, and it has expended, and is expending, very large sums of money in doing so.

It is, therefore, quite incorrect to say that the Western Australian Government does little or nothing to encourage and assist the mining industry, and one might think our grumbling objector would at last be silent; but, no, he has still a heavy shot in his locker. This time he cries that West Australian mines are no good any way, as the gold does not "go down" and the mines are of no value in depth, and he points to numbers of mines in proof of his statement in which the values have been soon lost. To demonstrate that it is quite an unwarrantable generalisation to infer that all will behave in the same way is hardly possible, without going into numerous geological and genetic considerations which would take too long to discuss at present, and the conclusion would depend very much upon the interpretation which should be placed upon the facts of the cases. In many instances the facts have been incorrectly or inadequately stated, often through want of acquaintance of the operators with points in the behaviour of the lodes which have an obvious and important significance in the eyes of a student of ore deposits, but which may entirely escape the observer—even a highly-skilled and practical man otherwise—who has not studied the scientific side of the business and trained himself to notice occurrences which may not appear to have any connection with the exploitation of the ore, but from which important deductions may be drawn by those who can refer effects back to the causes which have brought them about. It has rarely been recognised, for example, that it appears to be a very common feature of many West Australian ore bodies that they have been disrupted, by earth movements or faulting, along the planes of the lodes themselves, these movements subsequent to the formation of the ore bodies having re-opened the old line of fracture in which the lode was first formed. The good stone is often found suddenly to "cut out"—a term always highly suggestive of some form of faulting—and, as a rule, little search is then made to recover it. Frequently there is a reef of poor or barren quartz present alongside the valuable one, which is of later date of formation than the latter, and which is left standing while the good ore is taken out, but it is uncommon to find any rational deduction being made from the fact that such a condition is *prima facie* evidence that there was a re-opening of the old reef fissure to enable the later poor reef to be formed, and that in the course of the faulting movement which would result, the older reef would almost certainly become much broken and displaced. When it disappears suddenly and the poor reef continues, it is quite usual to assume that the two have joined one another and that the values are simply vanished, instead of search being made for the dislocated continuation of the good ore. It is not contended that this explanation applies to all or even to the most important cases of loss of values in the lodes, but many instances of it have come under my own observation, and there is a good deal of reason to think that many cases of curious separation of lenses of ore containing values may really be explainable by the faulting of an originally continuous body. In dealing with these lodes we are probably handling the case of deposits formed in very early geological times, during a period of much earth movement and plication of the region containing the mines, and therefore particularly liable to show much dislocation of the contained ore veins.

Another characteristic feature of the lodes of Western Australia is the unusual amount of secondary enrichment which appears to have gone on in most of them near the surface, especially in the zone of oxidation above the water level. This has often led to much disappointment when the deeper parts of the lodes have been reached, but it is a feature which is now becoming much better understood than formerly, and for which allowance is to be made. There is, however, much doubt yet as to the depth below surface to which its effects are perceptible.

In some cases the values disappear so suddenly at the water level that there is a temptation to speculate on the possibility of their having been removed by leaching upwards, there being a certain amount of constant drawing upwards of the ground-water by capillarity to replace the moisture removed by surface vegetation and evaporation. In an arid climate this action may be expected to be more marked than in a humid one. The possibility seems sufficiently feasible to require some sinking to be done in such cases in order to pass through what may be not an enriched but an impoverished zone.

As a matter of fact, good values have been found in Western Australian mines at the greatest depths to which mining has been

carried, namely, the 2,650 feet level of the Great Boulder Mine. So far as work has gone at that level, it is true that values have not been so satisfactory as at the 2,500 feet level, and there has been much fear expressed in consequence that this famous mine was at last failing. But some good ore has been obtained, and it must be remembered that at all the levels it has been often easy to miss the best ground until a great deal of exploration has been done. The following of ore in the Western Australian mines is anything but a simple proposition, the ore often being hidden behind what are apparently the well-defined "walls" of the reef, while the lode stuff between these is of little or no value. In almost all the mines of Kalgoorlie it has been found essential to do a great deal of boring across the strike of the reef to locate hidden ore, and the first drive along the lode has often been anything but a true test of its value. This local peculiarity must be recognised and allowed for, and time given to open the ground pretty thoroughly before jumping to conclusions about extinction of values. The whole history of the Boulder Mines from below the oxidised zone has shown a succession of pessimistic forecasts of their early decease, and from time to time the prospects of first one and then another of them have appeared very doubtful. Time and again, however, further exploration has brought about new developments and the position has improved, and there is therefore always much hope that perseverance will be well rewarded. All the principal mines show much more variation in their values at different points than is generally understood by the public, and it is owing to this feature of them that it is so difficult—indeed, almost impossible, in many cases—to make really reliable estimates of ore reserves. The only safe course is to keep the mining development a long way ahead of the ore-breaking, to give time for fresh ore bodies to be picked up before the older ones are worked out.

It is undeniable that in Western Australia, as in all other parts of the world, the lower levels of the mines have not been so productive as those nearer the surface, but it does not seem to me that in this respect they have shown any more lack of permanency in depth than those of most other mining fields, nor is there any satisfactory reason yet apparent why values should not be found to persist in them to quite as great depths as in any other mining region, say, to 4,500 feet as in Bendigo, or even to the immense depth of 6,000 feet at which mining in South Africa has been seriously contemplated. The grounds on which early extinction of values has often been predicted are mainly quite theoretical, and, notwithstanding that great advances have been made towards formulating a science of ore deposits, it cannot be denied that there is still very great conflict of opinion among the best authorities on the subject on the most fundamental propositions as to the mode and conditions of ore formation. For example, not very long ago a discussion was published as to the origin of a certain pyritic ore body, in which one leading authority held the view that it had been formed by magmatic differentiation from an igneous mass, another that it was an ordinary lode of hydrothermal or pneumatolytic origin, and a third that it was a metamorphic sedimentary deposit, all radically different and incompatible conceptions. While one school of opinion regards ore deposits as more or less chemical concentrations from the more superficial rocks of the earth's crust, due to circulation of liquid solutions through them, and another holds equally strongly that they arise mainly from emanations from plutonic sources, there cannot be said to be any accepted theory of ore formation on which it is safe to build practical conclusions as to behaviour of lodes in depth. The various hypotheses may be useful to guide exploration, but the only practical course is to sink down to see what the ground will show. This has been the mining maxim from its earliest days, and it is still as necessary as ever. No theory is yet so firmly established as to justify deductions being made from it without the check of actual trial.

A great deal of the fear that is expressed as to permanency of ore deposits in depth is often founded on what is really an entirely unproved assumption, though it has a certain amount of *prima facie* probability, namely, that in a deposit formed by ascending hot waters the metals would be likely to be in solution in the deeper zones while at high temperature and under high pressure, and would only be deposited as in ascending through the crust of the earth the temperature and pressure are reduced and the solutions come in contact with more superficial waters carrying precipitants. It is somewhat inconsistent that this view should be put forward as a reason for expecting falling off in value in reefs like those of northern New Zealand, which seem plainly to be of hydrothermal origin and outcropping probably at no great depth below the original outlets of the hot springs which formed them, and also for the pneumato-genetic

lodes of Kalgoorlie, the portions of which now accessible to us have most probably been formed at great depths under pneumatolytic rather than hydrothermal conditions. And when we come to consider the case of the gold-bearing alaskites, where we seem to be dealing with a transition stage between plutonic dykes and ordinary reefs, it is difficult to understand that either temperature or pressure can necessarily be the determining factors of deposition which they have often been assumed to be.

It seems to me that the mining industry has a right to protest against the very unscientific attitude taken by some persons claiming to be authorities who have allowed themselves to be carried away by deductions from the theories which they adopt with regard to ore deposition, and issued dogmatic statements as to what *must* happen to ore deposits in depth. In the present state of the science any such views can only be tentative, and should be clearly understood to be so. They carry more weight with the investing public than ought to be allowed to them, views which are the mere speculations of an authority being often taken to represent the demonstrated conclusions of science, and in consequence exploratory work which would be undertaken if these ideas had not been put forward may be restricted or abandoned, to the great detriment of mining.

To conclude this long address, I would wish to draw attention again to the exceptionally good opportunities offered by Western Australia to capital for legitimate mining operations, and also to men who have to depend on their own physical efforts to make their living for doing so either in mining or in farming pursuits. There is a great field for enterprising and steady young men who would learn the business of prospecting and working small mines, so as to be able to become their own masters and get mines of their own. Taking the various fields there is ample choice of districts. In the north the Kimberley goldfield is and has been for years past lying practically deserted, largely on account of the difficulties of transport and consequent high cost of all necessaries of life and industry. West of it there have been discoveries of copper ore, mostly rather inaccessible just now, gold, and wolfram; and on the coast alongside deep water at Yampi Sound there is a huge deposit of excellent iron ore which must before long be utilised. In the Pilbara goldfield, which is being now opened by a railway, there are gold, copper, antimony, tin and asbestos deposits, also monazite and diamonds. West Pilbara has copper, gold and antimony, and deserves much more attention than it has yet had accorded to it. In the Ashburton and Gascoyne fields there are copper and lead deposits, as well as gold, and the occurrence of coal measures gives expectation that coal may be found. All these fields which I have yet mentioned are very little opened up by mining, though minerals are well distributed through them, but are mostly taken up by pastoralists in extensive sheep, cattle and horse stations. In the Peak Hill and Murchison fields there is much stagnation at some of the older centres, but new discoveries are often made, and two good new districts—Meekatharra and Black Range—have come very much to the front of late years as gold producers. The Youanme district is also promising very well. At several points in the Murchison field there are lodes carrying copper ores, and there is one small tin-field lately discovered. West of the Murchison lies the old Northampton district, which has produced about £365,000 worth of lead ore, and £149,000 of copper ore, mostly before the goldfields of the State were discovered. Low prices for the metals and high costs of transport were the principal causes of this field being abandoned, and, being largely private property, there have been difficulties in the way of later prospectors obtaining access to much of it. The Yalgoo field south of the Murchison has had little production, but has several localities worth attention. The East Murchison and Mount Margaret fields have a large number of auriferous centres, and are anything but thoroughly prospected yet, while they contain dozens of partly-tried mines which deserve more opening up. The same may be said of the others of the eastern goldfields. The recent successes of prospecting operations on the Southern Cross belt are only an earnest of what may reasonably be expected from resumption of systematic prospecting elsewhere through the fields. The Bullfinch discovery early in the present year is within eight miles of the Golden Valley, at which the first gold was found in the eastern goldfields in 1887 and quite close to the track from there to the next discovery at Southern Cross. The Corinthian leases, some seven or eight miles further south, are likewise close to the road travelled by hundreds of prospectors for the last twenty-three years, but were not found till last year. Yet the lode forms strong outcrops of quartz which would attract the attention of any prospector. The fact that the surrounding country is lake flats possibly misled prospectors into thinking that

there were no outcrops to be found, low hills being quite imperceptible when one is travelling through wooded country. A great deal of prospecting could be advantageously carried on in many of the lake flats throughout the State, as many lodes are certainly covered and do not appear at surface at all. A few have been found here and there as at Lake Darlot and Comet Vale, but as a general rule very little has been done in the flats to look for lodes.

The southernmost field of all, that of Phillips River, contains gold and copper, and is the scene of the large enterprise of the Phillips River Gold and Copper Company, as well as of several smaller local mines. It was at first very inaccessible, and it is still rather likely to be a trying experience to visit it either by land or water, but a good deal has been done to render landing easier at Hopetoun, and a railway has been made thence to the main town of the district—Ravensthorpe.

There is still much unexplored country in Western Australia to attract adventurous people who desire to look for entirely new fields, and it is very possible that such may be found. At the present moment the feeling in the State is rather that it is advisable to prospect further the known fields than to go off into places in which it would be difficult to work profitably any discoveries that might be made, on account of their distance from formed lines of communication.

APPENDIX.

STATISTICAL DATA RELATING TO THE MINERAL INDUSTRY OF WESTERN AUSTRALIA.

Area of Western Australia ... ... 975,920 square miles

„ Proclaimed Goldfields ... ... 330,126 „ „

Leases in force 1909 numbered 2,105, comprising ... ... 28,919 acres, or over 45 square miles

Number of stamps employed 1909 3,572

Population of the State, June, 1910 282,124

Number of men employed in Mining—

1905	1906	1907	1908	1909

DISCUSSION.

The CHAIRMAN said a letter had been received from Dr. Henry Woodward, F.R.S., and a telegram from Sir C. H. Rason. Dr. Woodward's letter expressed his regret at being unable to accept the invitation to be present, and Sir C. H. Rason's telegram ran as follows:—"Much regret prevented attending. I am sure Montgomery's able Paper will convince many that all the prizes of mining in Western Australia are not yet drawn." Continuing, the Chairman thought the paper read by Mr. Montgomery was very encouraging both to prospectors and people who had their money in mines which might not be so flourishing as they wished. The author evidently did not think there was any reason why, if some mines were carried deep enough, something worth having should not be found. The little note of warning he had given, namely, not to be too ready to put their money into schemes which were floated directly anything was started in the shape of a find, was practical and of great value. There must be a good many finds in a large undeveloped country, but there should be a little more searching investigation into them before the British public subscribed money for their development.

[At this stage of the proceedings Admiral Sir Frederick Bedford had to leave the meeting, and the Chair was taken for the remainder of the time by the Hon. John McCall, M.D., Agent-General for Tasmania.]

Mr. T. A. RICKARD said it gave him pleasure to unite with others in complimenting Mr. Montgomery on his comprehensive and most timely paper. His own knowledge of the conditions obtaining in Western Australia was sufficient to enable him to appreciate the sincerity of the author's effort to give the facts in an informing manner. The paper, of course, was full of suggestive ideas, some of which were open to discussion. He joined with the author in emphasising the relation of mineral discovery to human industry, and of industry to empire. The search for metallic wealth and the exploitation of mineral resources were associated in the minds of most people with dubious financial exercises and gambling of a variously intelligent character; but Britishers hardly appreciated enough the fact that their overseas dominions were the sequel to gold-seeking, that the prospector blazed the trail of empire, and that while trade followed the flag, it was the pick that preceded the flag. The pages of modern history showed that Canada, Australia, and Africa were won by those who penetrated the waste places of the earth in the search for gold and silver, lead and copper; self-interest prompted their quest, but they built better than they knew, for they laid the foundations of civilisation. That was, however, a subject too big for casual reference. The author had given an excellent summary of the physiographic conditions affecting life and work in Western Australia. It was a healthy country, and he could well advise our young men to go there. There was a time when dysentery and typhoid were rampant, twelve or fourteen years ago, during the period of greatest expansion, when the conditions of living were haphazard and rough. But now, thanks to railways and water systems, Western Australia was a country in which a man could make a home. The members would have appreciated the author's analysis of the gold production and his explanation of the relation between the winning of gold from the ground as against the extraction of gold from the pockets of the credulous and greedy. The distinction was one that was properly made by a State mining engineer, and it was one that the public would do well to understand. Unfortunately, the amount of gold produced and the number of dividends paid did not serve as a measure of the profit and loss made in mining, for the capital involved—he did not say invested—far exceeded that which was required to find and equip the mines. Statistics were only misleading, for they did not concern themselves either with the derelicts on which money had been vainly spent, or with the inflations to which in times of excitement the market value of mines was subjected. If the author had been able to ascertain the total capital spent, not on the ground alone, but in London, in consequence of the mining and financial operations incidental to the exploitation of mines in Western Australia, he would have been compelled to give a figure so big as to be appalling; and if he had stated the proportion of productive mines among the thousands of leases granted to prospectors and syndicates, he would have been forced, by his regard for the truth, to name a ratio highly discouraging to the simple people who regarded every hole in the ground as a mine in the making. But such facts would not have surprised the experienced, for in mining, as in other forms of human enterprise, the proportion of success was small. Western Australia had been much in the limelight of criticism, but he doubted whether the story of her mineral development was essentially different from that of other famous mining regions. Western Australia was to blame for some, but only the lesser part, of the vagaries that disgraced the boom of an earlier decade. Most of the spoofery was exogenous. Nor need mining be blamed as an industry for the absurdities of which it was the unfortunate victim; one might as well blame the breeders of fine horses for the cheating of the race-course and the iniquities of the turf. The author had referred to the money lost by over-rating prospects and by over-valuing mines. At the present time renewed interest was being aroused in Western Australia by reason of the finding of remarkably rich ore near Southern Cross. It was evident that the Bullfinch Mine contained a fine ore body, but he thought that hardly justified the Premier of Western Australia making the statement publicly that "even Kalgoorlie and the Golden Mile sink into insignificance when one listens to reports regarding the (Bullfinch) property, which bids fair to eclipse anything discovered in the history of the

State." He (Mr. Rickard) examined the bonanza mines of Kalgoorlie when at their zenith, and he knew what it meant to compare a new district with the Golden Mile. Therefore he said that the Premier exaggerated greatly. It looked, however, as if mining in Western Australia was about to undergo fresh expansion, for promising new finds had been made at Yilgarn, Meekathara, and Youanme, and they would all unite in wishing that those discoveries might afford the basis for an enlarged and most profitable industry.

Mr. E. F. KELAART said he had listened with very great interest to Mr. Rickard's remarks, as he came from within a mile of that Throgmorton-street to which Mr. Rickard had alluded, and happened in 1899 to be a dealer in the market when mines were continually being floated. He could not help thinking of the vast amount of money the poor people of London had put into mines, owing to puffs in the papers and the marvellous descriptions that had been given, but he supposed people would be sportsmen and go into mines on the chance that the speculation might turn out well. When he was on the market there used to be mines put forward which he half suspected never existed; in fact, there was one mine he remembered which he dealt with himself and dealt with on the basis that the mine never existed. He did not hold a brief for the Premier of Western Australia at all, but he was informed that the mine referred to by Mr. Rickard was 145 acres in extent, and that reports had been received from mining engineers that down to 100 ft. there was so much, which on being totalled up came out to seven-hundred thousand. There were many things ready to be floated and people were racing to see who should get there first, and he was glad to have been present at the meeting to gain experience which would prevent him and his friends being so ignorant as to jump into things without enquiry.

Mr. E. T. SCAMMELL hoped that the Government of Western Australia would circulate the paper very widely; it should certainly go to all the mining institutions and mining schools, and also to the leading stockbrokers throughout the United Kingdom. The warnings on the one hand and the encouragements on the other given by the author should be known to stockbrokers, and if through them the information reached some of their clients it would be a very useful thing.

The CHAIRMAN (Dr. McCall), in moving a vote of thanks to the author, said Mr. Montgomery was for many years geologist to the State he himself had the privilege of representing in London, and it gave him great pleasure, as an old friend of Mr. Montgomery's, to be able to say that the people of London could accept his word about any mine without the slightest question. Mr. Montgomery had no other interest than that of the legitimate development of the country he so ably represented. He was glad to hear that the promise for Western Australia was so very good, and that the author believed there were opportunities for developing mines even in those areas where they had been working for some years. That he believed to be the case in many of the States of Australia; even within a few miles of profitable mines discoveries were being made which set one wondering why they had not been made before. Only recently there had been accounts of important discoveries on the west coast of Tasmania, quite close to the silver fields, not very far from Mount Lyell, a mine that had been known for many years. With regard to the Bullfinch Mine, he thought there might be something to be said for the Premier of Western Australia. He held no brief for that gentleman, and did not know him personally, but he thought the Premier qualified his remarks by saying, "When one listens to reports." He did not think Mr. Wilson attempted to vouch for what had been said by the prospectuses of promoters in connection with the Bullfinch at all. He regretted that Sir Frederick Bedford had been unable to remain, because he had been Governor of Western Australia, and had been well acquainted with Mr. Wilson, and might have been able to speak with more certainty. He still thought that the quoted words were qualified, and that they hardly gave a definite opinion in support of the Bullfinch, but were simply to the effect that if what was said was true, it was a very wonderful proposition. It had not been the policy in Australia to allow Government officials or any Government servant to take part in guiding the public in connection with mining properties. Personally, he was strongly in favour of the proposition tha the Government should in some measure take a responsible part in the placing of properties on the market, because he saw no reason why the Government should not allow Government geologists, men of very high standing, to give an opinion for the public benefit. After all, it was only the opinion of one man, but it had the advantage of being the opinion of a man qualified to express an opinion. It might be advisable even to go further, and allow the prospectuses to go forward with the approval of the Government. The Government were practically the owners of the mine, and, therefore, partly concerned in the proposition, and if it were well known that a prospectus issued without that approval was probably a shady one, the public would receive great protection. Whenever he had expressed himself in that direction before he had been always informed that the London public knew very well how to look after themselves. If that was the case, there must be a very large number of people just outside London who had not been so fortunate. The experience in Tasmania was that during the time Mr. Montgomery was there, there were no "wild cats." Attempts were made, but Mr. Montgomery was ready at all times to expose them, with very great advantage not only to the people but also to the country, because after all it never paid any country

to have money wasted, whether in connection with mines or anything else. At the request of the acting Agent-General for Western Australia he offered his apologies to the meeting for not being able to remain and take the chair for Sir Frederick Bedford; he was due to attend a meeting of the London County Council and had to retire early.

Mr. BYRON BRENAN, C.M.G., seconded the motion, which was carried.

Mr. A. MONTGOMERY, in reply, expressed his obligation to Mr. Rickard for the very careful way in which he had criticised the paper. It was a great pleasure to him to have a gentleman of Mr. Rickard's standing in mining matters taking sufficient interest in the subject to give very careful attention to the paper. With regard to the health of Western Australia, the death-rate was the same as the average of the Commonwealth generally, about eleven per thousand of late years, and considerably better than that of the principal European countries. Doubtless that was to some extent due to Australia being a young country without a large proportion of old people. But still the low death-rate in the Australian colonies showed that on the whole the country was very healthy. With regard to the question raised by Mr. Rickard as to the amount of capital invested in mining countries, he was well aware of the difficulty of getting a good basis on which to discuss what was proper expenditure and what should be charged against the industry; but he thought, as an industrial matter, the money which was made and lost in dealings in shares could not be said to be more than an exchange from one pocket to another, one man gaining and another man losing. As an industrial concern the amount laid out in mining work was the basis on which to judge whether the returns had been profitable or not. The amounts paid out for all sorts of work done, some of them expenses of management, were part of the necessary expense, but he thought distinction should be drawn between money which was laid out in necessary work in connection with mines and money which was made and lost in dealing with shares, flotations, and so on, where a few persons drew a large amount of money from shareholders for a property which might not be valuable. It was necessary to separate as clearly as possible the share-dealing aspect from the purely industrial aspect. As a civil servant he could hardly express any opinion at all as to the remarks of the Premier he had the honour to serve, but he thought the Chairman had already dealt with that matter as far as was necessary. As to recent discoveries, it had struck him as serious that during the last few weeks there had been so many concerns put upon the market in the bad old way, properties offered to the public on which nothing or next to nothing had been done, which were simply put forward because they were in the vicinity of a well-known concern. He was afraid that in that matter the public must protect itself. If people would speculate in untested concerns he did not know that it was necessary to be very sympathetic with them if they found there was nothing left of the "pig in the poke" but the squeal. With regard to Government officers giving reports of mining ventures, while there was a good deal that was desirable in this suggestion, he thought it would be found a somewhat difficult one to work out practically, because Governments were usually somewhat slow, and the public, when excited, demanded great speed. From his experience he did not think, if the market were at all lively, the public would wait for Government sanction—dealings would go on just the same. It would be a precaution which the public might well insist on having for their own protection, but as things were constituted he was afraid there was not a deal of hope that it would make much difference. By the last mail he had heard that the Western Australian Government had been attempting to do something in a general way by sending out not only the whole of the geological staff but the whole of the water supply staff to explore the line of country running from Southern Cross to Murchison. It was a difficult country to enter on account of want of water, and a number of wells had been put down, and the country was now being opened up. He thanked the Society for giving him the opportunity of bringing the claims of Western Australia forward, and on behalf of those present expressed his thanks, first to Sir Frederick Bedford, and secondly to Dr. McCall, for so kindly occupying the Chair.

FOURTH ORDINARY MEETING.

Wednesday, December 7th, 1910; Sir WILLIAM H. WHITE, K.C.B., LL.D., Sc.D., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Andrews, Neale, The Midland Iron Works (Newark), Limited, Newark-on-Trent.

Chamberlain, Frederick, 23, Herbert-street, West Bromwich.

Chater, Cecil William, Assoc.Inst.M.M., c/o Messrs. Mower & Co., Rangoon, Burma.

Clarke, Miss Alice Dolores, 24, The Grove, Boltons, S.W.

Hedley, Perceval Manfred Florance, The Studio, 16A, Soho-square, W.

Kiralfy, Charles I., 141, Holland-road, W.

McClean, William Newsam, 63, Evelyn-gardens, S.W.

Marlow, Thomas Gibbons, 138, Telford-avenue, S.W.

Merrick, William Altwicker, 5, Carlisle-street, Marylebone, W.

Smith, Samuel Joseph Woodham, 30, Fleet-street, E.C.

The following candidates were balloted for and duly elected members of the Society :—

Barrington, Mrs. Russell, 4, Melbury-road, Kensington, W.

Bruce-Williams, M., Green Hurst, Beaconsfield, Bucks.

Hepburn, Edward, Monkridge, Sidcup, Kent.

Jacobson, Richard, 70, Shoe-lane, E.C.

Laing, Miss Theresa T., Etal-manor, Cornhill-on-Tweed, R.S.O., Northumberland.

Wentworth-Sheilds, Francis Ernest, M.Inst.C.E., Docks Engineer's Office, Southampton.

Wolfenden, Stuart J. Norris, Conservative Club, St. James's-street, S.W.

The paper read was—

THE PANAMA CANAL IN 1910.

By Vaughan Cornish, D.Sc., F.R.G.S., F.G.S.

Introduction.

On July 11th, 1910, I arrived at Colon on the R.M.S.P. *Atrato*, and remained on the Isthmus inspecting the Canal works until the 27th, when I left for Jamaica. Returning to England by the same route, I spent two more days on the works during the month of August. I was accorded every facility for study, visiting the three divisions of the Canal in the company of the divisional engineers, going over the relocation works of the Panama railroad, and repeatedly visiting by myself positions which seemed to me of critical importance. Having paid a visit of similar duration in April, 1908, as well as a flying visit in January, 1907, I was already acquainted with the main features of the work.* I have to thank Colonel G. W. Goethals, chairman and chief engineer, and his colleagues for their great kindness. They received me as a friend, and gave me most generously of their time. To me it has been a privilege and delight to see this great work growing under their hands.

The Canal, as it is to be, is illustrated by the plan, profile and sections which accompany this Paper. They show, among other things, the following principal characters—viz., a total length from deep water in the Caribbean to deep water in the Pacific of about 50½ miles; a minimum depth at mean tide of 41 feet; a minimum bottom width of 300 feet; a sea-level canal surface of about seven miles at the Caribbean or Atlantic end, and of about 8½ miles at the Pacific end, the remaining portion being a high-level canal sustained by dams. From Gatun at Mile 8 to Pedro Miguel at Mile 39, the surface is to be at 85 feet above mean sea level, and the bottom excavation +40 feet,* and between Pedro Miguel and the Pacific sea-level portion there are nearly three miles occupied by locks, and by the small Miraflores Lake, in which the water will stand at +54⅔ feet. There will be a double set of three locks at each end of the high-level portion. Each lock has a lift of about 30 feet, a usable length of 1,000 feet, and a width of 110 feet. Intermediate gates, however, will be used for ships of ordinary size, which will reduce the amount of water required for lockage by from 30 to 40 per cent.

When I visited the Canal two years ago I was not able to satisfy myself as to the quality of the foundation upon which the Gatun Dam was to be built, and the plans for the dam itself were still undergoing repeated modifications. There was also little to show at that time whether there would or would not have been engineering difficulties of an unusual nature attendant upon the cutting of a sea-level canal. Lastly, the details of the Pacific Division (from Pedro Miguel southwards) were not then decided. It is with these matters that I shall principally deal in this Paper.

The Panama Canal is divided, like ancient Gaul, into three parts. First, the Atlantic Division from opposite Toro Point up to and including the Gatun Dam and Locks, a distance of eight miles, under Lieut.-Colonel Wm. L. Sibert. Second, the Central Division from Gatun to Pedro Miguel, thirty-one miles, under Lieut.-Colonel D. D. Gaillard; this division comprises the Culebra Cut. Third, the Pacific Division, under Mr. S. B. Williamson, from Pedro Miguel to the deep-water entrance at the Pacific, or southern end, a distance of eleven miles.

The Atlantic Division.

Foundations of the Gatun Dam.—The placing of a dam at Gatun to hold up a head of about 85 feet of water was the principal modification introduced by the Americans in the former plans for a high-level canal. By having a very high dam at the lowest possible position in the valley of the River Chagres they obtained a greatly increased supply of water for lockages, about enough to enable the Canal to be worked to the maximum of its mechanical possibilities. Much alarm was, however, caused by the current version of the nature of the foundations of the dam. This version was an erroneous one, but there is little wonder that it was prevalent, seeing that it was based upon the section and borings published in 1906 by the Board of

* See *Geographical Journal*, February, 1909.

* The levels are reckoned from mean sea level + and –

Consulting Engineers appointed by the President of the United States. This section shows the impervious clay which forms the floor of most of the valley to be traversed by two old river channels of considerable width, and reaching a maximum depth of about 260 feet. These were stated to be filled only with sand, sand and gravel, sand and shells, and such-like porous materials. The majority of the Board reported, moreover, that "it is highly probable, if not certain, that at various points the material [at Gatun] is sufficiently loose in texture to permit seepage or percolation in dangerous quantities."

In common with many others, both engineers and amateurs, I was unable, in 1908, fully to appreciate the reasons which led Colonel Goethals and his colleagues to consider such a foundation safe. Since then, however, I have read the evidence given by Colonel Goethals at Washington in 1909, and have also gone further into the matter during my recent visit to the Canal works. Apparently the persons who made the borings did not describe correctly the results of their work. What they actually did was this:—They put an iron pipe of about six inches in diameter down to about twelve feet below the surface. A nozzle attached to a hose was inserted, and water was forced down under pressure. Gravel, etc., welled up, and the material was classified accordingly. But the hole thus formed maintained itself without lining or casing to a depth of 270 feet, no sloughing in of the sides taking place. This fact indicated to Colonel Goethals, and, I suppose, to other experts, that the gorges were really filled with a good material, and that the borings had been wrongly described. Since Colonel Goethals arrived on the Isthmus in 1907 the gorges have been re-examined by the same method, but whenever a change of material occurred the water was stopped and a core of the material was obtained. In this way it was found that the gravel, sand, etc., were "surrounded by clay, compact and hard, and absolutely impervious to water."* In the course of this evidence Colonel Goethals speaks, however, of a top layer of sand and clay varying in thickness from zero to 80 feet as being pervious to water. Apparently even this portion is not, however, appreciably porous, for I now learn that a test-pit 12 feet by 12 feet has been dug by hand to a depth of −80 feet and that no water rose in the pit. The gravelly part of the material was cemented with clay, and did not allow percolation when subjected to a water pressure equal to what they will have to stand when the lake is full. Other tests have been applied—*e.g.*, two pits have been made and placed in electric communication. A solution of sal-ammoniac being introduced into one of them, no increase of the electric current has occurred, showing that there was no seepage into the second pit.

* Colonel Goethals' evidence at Washington, February, 1909.

As a result of these and other tests it has been decided to revert to the first plan of a dam dumped on the surface without sheet-piling beneath. In the early days of the work on the Isthmus the engineers do not appear to have had sufficient data to enable them to answer effectually the fire of criticism and suggestion from a zealous public, and features such as the proposed sheet-piling were introduced as concessions to nervousness. The effect was not altogether happy, for it gave the idea that the experts did not quite know their own minds. Probably constructional work commenced a year too soon on the Isthmus. Now, however, neither the dam nor its foundations appear to cause the engineers in charge any anxiety, and public apprehension in America seems to be at all events quiescent, if not extinct. There may be an impression, however, that American engineers are somewhat venturesome in these matters. That those in charge of the Panama Canal are not taking risks in the matter of foundations is, however, indicated by the plans for the dams at Pedro Miguel, to which far too little attention has been given by the outside public. At Pedro Miguel the west dam supports a maximum head of 45 feet of water, or about one half that against the Gatun Dam. The material underlying the dam is impervious, with the exception of a stratum of gravel near the bed of the Rio Grande. A trench has been cut through this gravel to rock and filled with clay. Again, with regard to the wall on the east of the lock, "the natural surface of the ground between the east lock wall and the adjacent hill is at sufficient elevation, but the upper portion is more or less pervious. To cut off any possible flow the lock wall will be turned towards the hill, with which it will be connected by a concrete core wall resting on rock 550 feet long, 4 feet thick at the top, and 10 feet at the bottom." *

The Gatun Dam.—The dimensions, form, and material of the great Gatun Dam are shown in the plans and sections. At the time of my visit the rock fills were built up to +70 feet, the hydraulic fill or fine material pumped in between the rock fills being, of course, somewhat lower.

* Annual Report of the Isthmian Canal Commission for the fiscal year ended June 30th, 1909.

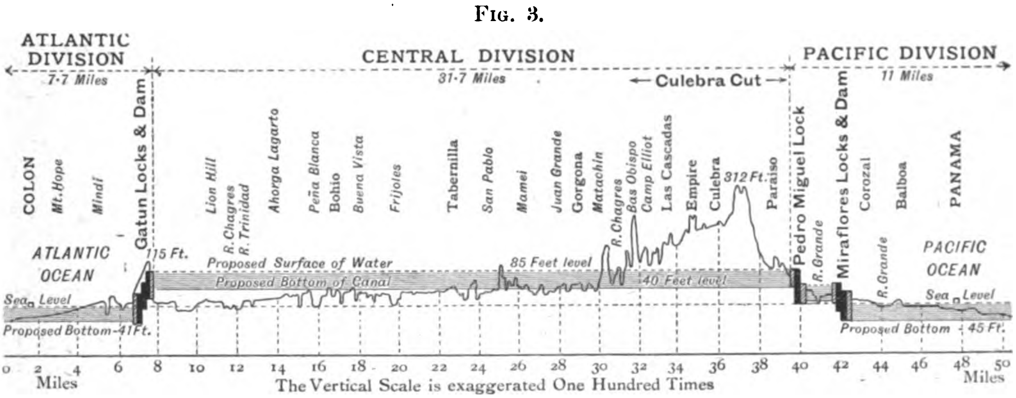
The water drains off from the hydraulic fill through pipes, and the silt settles and packs tightly. Essentially, the rock fills secure stability whilst the hydraulic fill secures impermeability. The former ensure that the dam shall not be pushed bodily to the north by the pressure of the water in the lake. The latter, which occupies the space between the rock fills, ensures that the waters of the lake shall not percolate through the dam. The devices by which an immovable and impervious dam is constructed of loose and fragmentary material are an excellent example of the subtle methods of the civil engineer. It should be noted that the material on which the engineers rely for the impervious centre of the dam is the same in substance as that on which the dam is founded, for they simply pump up the alluvium covered by waters derived from the Chagres and other rivers in the vicinity of sections alone. The slope of the surface—one in ten—is so gentle that the structure resembles a gradual swelling of the ground. The lower slopes are already so much covered with grass that I found myself walking on the dam before I realised that I had left the original surface of the ground. Moreover, no diagram can do justice to the fine-grainedness of the dam. The smallest dots which can be made upon paper are not too small to represent, on a true scale, the great blocks of the rock fill, whilst the fine silt of the hydraulic fill is actually finer in texture than the small dots made by a drawing pen.

One of the questions relating to the Gatun Dam which has been answered, more or less completely since my visit in 1908, is whether it would be too heavy a load for the ground to carry. If so, the materials would subside, and the ground not far from the dam would bulge

Fig. 3.



Profile of Canal.

This section is reproduced, by permission of the Royal Scottish Geographical Society, from the illustrations to Mr. Vaughan Cornish's paper in the *Scottish Geographical Magazine* of August, 1910.

the dam itself. This fact is advanced as an argument in favour of the impermeability of the foundations, but I think that the case for the foundations is better if it be left to rest on the experimental evidence only. The argument quoted above is not a good one, because it leaves out of account the possible effect of difference in the mode of deposition of the material.

With regard to the stability of the surface of the rock fill, one sees at once that the artificial hill is much better than natural slopes in which alternations of porous and impervious materials occur. The rock fills have no such impervious layers to become lubricated surfaces, such as cause the slipping of superincumbent material.

The appearance of the dam *in situ* gives a feeling of greater confidence in its stability than is to be attained by the study of plans and up. It is extremely satisfactory to note that there has been no bulging of the ground. This is due to the flatness of the dam, as is shown by the following experience on the relocation works of the Panama railroad. The new line was to run on an embankment some 90 feet high across the Gatun Lake, parallel to, and about half a mile east of, the old line. The ground, however, was unable to carry the load. The rock fill, dumped from a trestle, sank and spread, and the ground contiguous to it bulged up, or "humped," badly. It should have had, in fact, a load of rock laid upon it to keep it down. When the dumping of the rock fill of the Gatun Dam was commenced the engineers took no pains to spread the load, and, the pile growing steeply, a similar subsidence of the fill took place. It was a matter of small intrinsic importance, as the distribution of pressure would have

soon been readjusted by the dumping of more rock alongside. Nevertheless, the occurrence was unfortunate, as it gave rise to great alarm in the United States. The subsequent growth of the dam (which now has its final width and of which the height grows gradually, and the surface slope remains constant to within 25 feet of the top) has been unaccompanied by any deformation of the neighbouring ground. So little cause does there appear to doubt the capability of the ground to bear the heavy load piled up at a gentle slope that the engineers have not hesitated to create a deep hollow in the ground just north of the dam in the process of pumping up the hydraulic fill. It should be observed that the ground to the south of the dam will be actually relieved of much of the strain when the water is allowed to rise to its final level of +85 feet, for this will further weight it down against the thrust of the dam. Also the heavy but loose materials of the southern rock fill of the dam will be subject to less gravitational stress when the lake is full than during the process of construction, for the pressure of the water acting, as is well known, at right angles to the face of the slope tends to push the material northward, whereas gravity tends to make it tumble to the south. This thrust of the water tends, of course, to push the dam bodily northward. On both accounts the northern face of the dam is built at a still gentler slope than the southern.

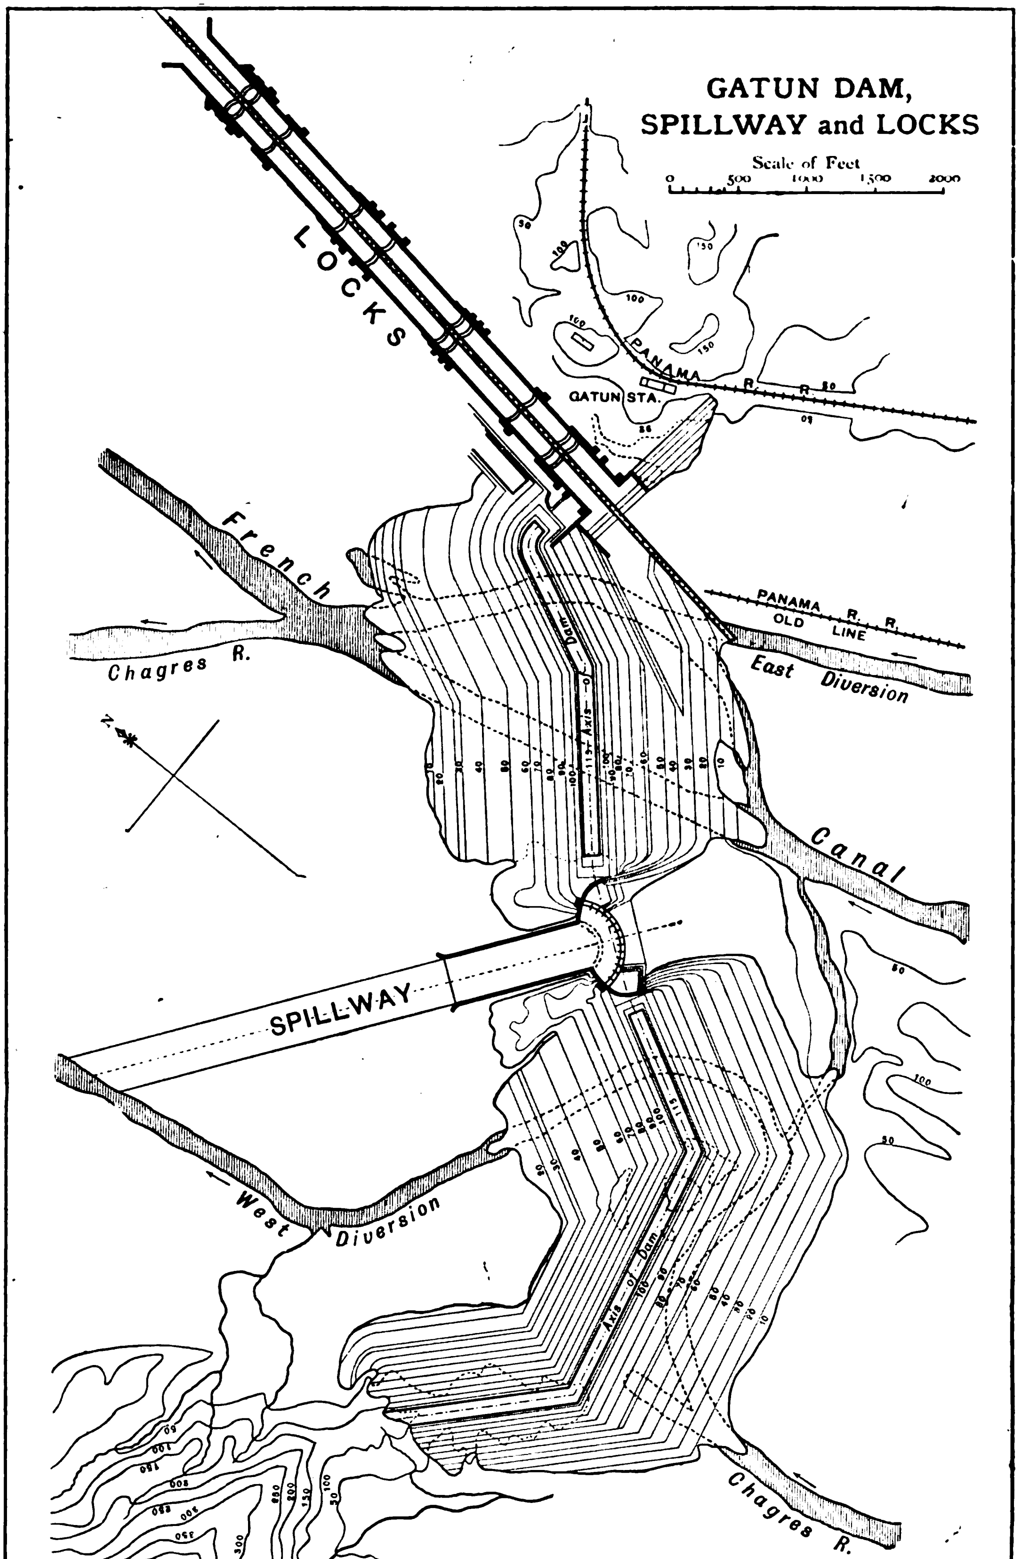
An important stage in the construction of the Gatun Dam had been reached before the date of my recent visit. The Chagres had been flowing to the sea by the channel marked on Fig. 4 as the West Diversion. Meanwhile the channel, called the Spillway, had been prepared. This is a concrete-lined channel, 300 feet wide, cut through a low rocky hill which projected above the valley floor, and is included in the dam. The sill, or opening, of the channel is 10 feet above mean sea level. When the West Diversion was closed the Chagres had a depth of about 14 feet. The river made a hard fight to keep its course. Great masses of rock dumped in the channel of the West Diversion were whirled away by the current. Then quantities of iron rails were dropped across the wooden trestles, and these held up the fresh loads of dumped rock. The trestle cracked under the strain, but held. Meanwhile pressure was relieved by pumping silt into the channel just above the trestle, thereby producing a shoal, and finally an island. By these means Colonel Sibert, the Engineer-in-Charge, finally succeeded in inducing the river to abandon the West Diversion and flow through the Spillway. It now pours in a swift torrent through this broad artificial channel, the chocolate-coloured waters curling back in a series of standing waves. The surface of the water is generally at about +14 feet, and this maintains a large mere or small lake above the dam, from which protrude the telegraph poles along the old line of the Panama railroad. This state of affairs will remain until the time comes for closing the Spillway by a concrete dam, about eighteen months hence. Then, when the river has been mastered, the lake will slowly fill to +85 feet, after which the surplus waters of the Chagres and other rivers will be allowed to escape through the sluice gates.

I have said that a merit of the scheme for placing the dam at Gatun was the storage of a great amount of water. Should more storage capacity be required in the future, it can be obtained by dredging up the bottom of the lake, and, in order to provide for such a possibility, the sill of the uppermost lock has been placed at +37 feet instead of +40. If, therefore, the bottom of the lake were lowered three feet there would still be sufficient depth over the lock sill with the minimum quantity of water in the lake, whereas the quantity stored when the surface is at +85 feet would be considerably increased.

The Central Division.

The Central Division extends from Gatun to Pedro Miguel, and is in the charge of Colonel D. D. Gaillard. From Gatun to the halfway point of the Canal (Mile 25, near San Pablo) there was hardly any excavation needed, the natural level of the ground along the line of the Canal being generally below +40 feet. Along this line the trees have been cut down, and the brushwood and scrub cleared away. Over the remainder of the 164 square miles of Lake Gatun the forest will be wholly or partially submerged and the trees left to rot and die, the process of clearing being too expensive. From Mile 25 to Mile 31, above Gamboa bridge, there is a good deal of excavation of soil being done. The work was particularly interesting at the time of my visit on account of the circumstance that the Chagres was here being turned into the canalized channel. About Mile 31, at the sharp bend above Gamboa bridge, begin the eight miles of continuous excavation in basalt rock, known as the Culebra Cut. At the north end the lowest or pioneer cutting was down "to grade"—*i.e.*, to the final level of 40 feet above

FIG. 4.



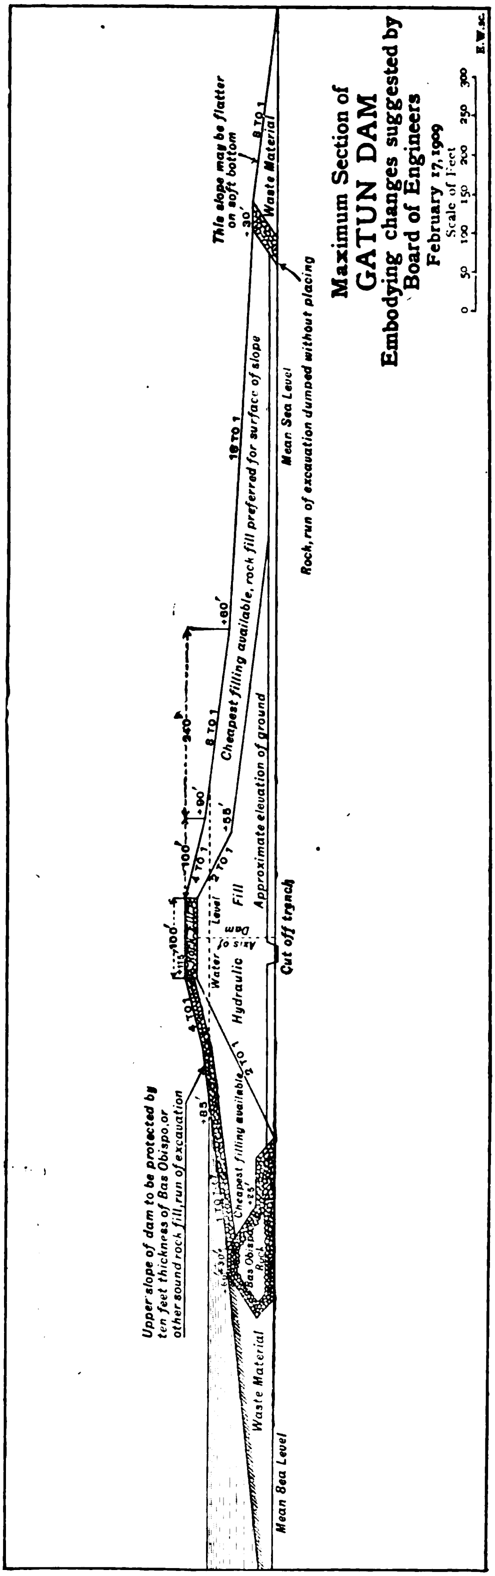
Emery Walker sc.

sea. This is three feet below the low-water surface level of the Chagres at Gamboa bridge near by. A barrier of the natural soil had been left to keep the waters of the Chagres from flooding back into the Cut. All rain-water accumulating here has to be pumped across this barrier into the Chagres. From this point the level of the bottom, or pioneer, cut rises as far as the suspension bridge at Empire, where the level is +111 feet. Thence the pioneer cut slopes southwards, so that the level is +95 feet at Gold Hill and +45 feet under the railway bridge at Pedro Miguel. These slopes are maintained partly for the purpose of draining the Cut, partly in order to facilitate haulage of the trains loaded with the spoil. Only empty cars have to be hauled up the slopes. It is in the Culebra Cut that the great collection of machinery is to be seen, particularly the huge array of steam-shovels and rock-drills. These are continually being shifted in position. As each steam-shovel is shifted, its water-supply pipe has to be shifted after it. As each rock-drill is shifted the pipe conveying compressed air has likewise to be shifted. The water-pipes and air-pipes have to be laid in the Cut, and they must be so placed as not to interfere with the trains, full and empty, which pass every point on the Cut at intervals of about two minutes. At Empire the pipes have to be carried across the Cut, for which purpose a steel suspension bridge was built. This will serve to give some slight idea of the amount of detail which has to be attended to in this division. The organisation, however, has long been perfected here and elsewhere on the Canal works, and these things now appear to the visitor to arrange themselves.

The most impressive view of the Culebra Cut is that from Culebra town, looking down into the trench and across to Gold Hill. The summit of this hill is 665 feet above the sea, and at +534 feet commences the escarpment begun by De Lesseps and continued by the Americans. The pioneer cut below is now* at +95 feet, so that the present escarpment is 439 feet in height. This is only ten feet less than that which will finally be visible when the Canal is filled with water to +85 feet. Those who visit the Canal works when excavation is complete to +40 feet, and before the water is allowed to flow in, will see an escarpment of 494 feet. The summit of the hill is 570 feet above the present pioneer cut. These dimensions do not differ much from those of the cliffs at Sidmouth. The bright green

* These levels refer to July-August, 1910, the date of my last visit.

FIG. 5.



vegetation of the summit, and the brilliant red of the earth below recalls also the colouring of the cliffs of South Devon. Only at the lower levels does the black basalt appear. The scale of the scenery is only gradually realised when one notices the little figures of the men creeping about in the bottom of the Cut among the great fragments of rock dejected by dynamite from the walls of the Cut.

When I visited the Canal works in April, 1908, the whole of the Culebra Cut was being got out as for a bottom width of 200 feet. In October of that year, however, it was decided that the bottom width should be increased by no less than 50 per cent.—viz., from 200 to 300 feet. This important change, coming at a somewhat late stage in the operations, appears to be responsible for much of the increase in the slides. These so-called slides are so serious a trouble that the centre of anxiety is now shifted from the Gatun Dam to the Culebra Cut. The widening of the Cut necessitated the cutting of fresh slopes through the clay which covers the rock to an average thickness of 15 or 20 feet. These slopes had become covered with vegetation and were fairly permanent, but when the bare ground was again exposed to persistent rains they began slipping again. But the trouble does not cease with the sliding of superficial clay. The solid rock beneath it on the banks sometimes breaks like ice in the ice-fall of a glacier, and, which is still worse, the downslip of material above is not infrequently accompanied by a humping up of the basalt rock which forms the present floor of the Cut,* and is the material of the bed or floor of the future Canal. This humping up of the bottom of the Cut during the present wet season (commencing May, 1910) has occurred at many places. The rise of the floor has been as much as 20 feet. A common view with regard to slides seems to be that as the quantity of material apparently available for sliding is not more than can be cleared up by a few steam-shovels, the sliding is not serious. Even if the calculation of quantities be correct, however, this view is, I think, unsound. What matters most is not the slipping of the banks, but the humping up of the bottom. As long as the bottom of the Cut is subject to humping it would be futile to let the water in and attempt navigation. If things went on as at present the depth of water at any point might at any time be reduced from 45 feet to 25 feet.

Of all physical processes those going on in earth slides are at the present moment the most worth study by the engineers on the Canal. These occurrences appear to me to be closely related to gravitation waves in water, and to be most easily comprehended by a bold application to them of the principles and the terminology in use by the student of superficial waves.

The "Slides" in the Culebra Cut.—Everyone is familiar with the circumstance that if on a water surface there be anywhere produced a steep slope—*e.g.*, the hole made by a falling stone or the hump made by a submarine explosion, the force of gravity produces a wave or waves. The hump subsides, and the water contiguous to it humps up. The same thing happens with the solid surface of the earth, only that the stiffer material does not go on undulating, but generally stops short at the formation of a single trough and crest, or one complete wave. I suggest the term "subsidence wave" for this occurrence. This phenomenon of a surface wave produced by subsidence of soil or rock presents itself in two forms. The first is that already described, arising from the imposition of an additional load upon a part of the natural surface, resulting in a rise of level of an adjacent part of that natural surface. The phenomenon, which is a familiar one to railway engineers, has nevertheless occurred so much more freely than was foreseen, that the proposed route of the Panama railroad from Gatun to Bohio has had to be entirely abandoned and a new route adopted, which avoids the alluvium of the Chagres valley.* The second form of the subsidence wave in soil or rock occurs not from the addition of a load but from the removal of a load, or of lateral support. Such subsidence waves or wave slides occur at many spots from Las Cascadas, near the northern end, to Paraiso, near the southern end of the Culebra Cut, a distance of about six miles.

The term "slide" conveys a misleading idea of what occurs. It suggests travel of superficial material down an incline. It suggests that every part of the material moves forwards *and downwards*. This is, indeed, what happens when shallow soil is stripped from a sloping face of rock during heavy rains.

* I am told that when the rock breaks above there is always a humping of the rocky bottom of the Cut.

* When a railway embankment is piled too steeply for the character of the material of which it is composed, the material spreads. I saw a case on the re-location works of the Panama railroad in a place where the ground was firm enough to support the load so that there was no humping of the natural surface. The slope of the embankment was, however, waved, the toe being steep and the middle part much flattened. The characteristic face of dumped material is plane. A waved surface is the sign of subsequent subsidence.

But when the soil or disintegrated rock is deep the movement of the so-called "slide" is no mere slanting descent, for the forward movement is accompanied by subsidence at the back and elevation in front. When we reflect that gravity acts vertically, we see that this form of movement ought not to cause surprise. In the case of a slide which occurred on the east side of the Canal opposite to Whitehouse* the first thing which was noticed was that the steam-shovel in the Cut was being lifted. The higher slopes were then examined and it was discovered that a crack had appeared in the soil. Afterwards the soil below and in front of this crack foundered, moving forwards and downwards with the formation of the crevasses which are the usual accompaniment of landslides.† It is easy to understand that in the hump the horizontal pressure on the earth has been increased, that it has been squeezed. The foundered part, on the contrary, having broken away from the earth behind, which remains stationary, is less squeezed than before, so that, relatively to its former condition, it may be spoken of as having undergone tension. Between the foundered part where there has been relief from lateral squeezing, and the risen part which has been subjected to an increased squeeze, there should be a nodal line where there is no change of pressure. In more than one slide it has happened that a line of rails laid upon a berm or ledge in such a situation has suffered no vertical displacement. In one of the slides which I saw, the horizontal movement in the hump was about 30 feet and the vertical about 18 feet. The whole occurrence is the conversion of an inclined plane surface into a waved surface, the foundered half being the trough of the wave, the rising part the crest of the wave. As in many other kinds of waves, so here, there is on the surface a series of minor inequalities comparable to ripples, but on account of the brittle nature of the material these take the form of cracks or crevasses, instead of wrinkles or wealds. The crevasses occur on the humped-up part as well as on the foundered portion.

Where humping of the bottom of the Cut occurs, the treatment which will be adopted will be to lessen the angle of the slope above until gravitational equilibrium is reached, which can only be known when it is found that no more humping occurs. Then if the water be allowed to fill the Canal its weight would constitute an additional security against either the bulging in of the sides of the Cut or the humping of the bottom. Superficial running of wet soil or clay might still continue, but would cause no anxiety. It would readily be removed from the Canal by dredging. This sloughing, as it is termed, is indeed viewed with satisfaction by the engineers as removing some of the weight which produces the true slides or wave slides, or subsidence waves. The slides are mainly an occurrence of the wet season (May–December). The sudden tropical downpour, of the kind which causes floods, washes off the surface layers of the soil and clay, causing the above-described sloughing. By removing in a broad, shallow, semi-liquid stream some of the soil and clay, and by puddling the surface of what is left, such downpours are sometimes beneficial in their action. It is the steady drizzle which does most harm, the kind of rain which soaks in and waterlogs the mass.

The worst slides hitherto have not occurred directly under the summit of Gold Hill, but south and north of it on the east side of the Canal, and at Culebra town on the west side. It seemed to me that the pressures which caused humping of the bottom of the Cut were always the result of underground flow of watery material.* The whole weight of Gold Hill, even at the steep slope at which it stands, does not squeeze up the bottom of the Cut where there is no watery flow. The humping of the floor of the Cut reminded me of the bulging of a wood pavement when a water-pipe has burst. The increase of fluidity due to sinking in of rain-water diminishes friction and transmits the weight of the superincumbent material laterally. The heavy rainfall of the Isthmus (90 inches per annum at Culebra), and the great depth to which the weathering of rocks extends in the humid tropics, probably accounts to a great extent for the unexpected amount of trouble from the combined subsidence and humping in the wave slides.

However this may be, their great development lately goes far to provide an answer to the hitherto unanswerable question "Should the Canal have been sea level or high level?" The main argument of the Board of Consulting Engineers against the high-level canal was that in an undertaking of such magnitude and importance, "no doubtful experiments should be

* This is near the north end of the Cut. Here the rock on the east side dips towards the Cut, and subsidence above with humping below is frequent. On the opposite side the rock dips away from the Cut, and, though covered with clay, there are no slides.

† A shovel has risen as much as nine feet in the course of an afternoon.

* Where the rock has broken above and humped below, it has had joints either vertical or inclined towards the Canal.

indulged in, but, on the contrary . . . every work of whatever nature should be so designed and built as to include only those features which experience has shown to be positively safe and efficient."

This dictum referred particularly to the contrast between a dam at Gamboa, founded on good hard rock, and the proposed earthen dam at Gatun founded on alluvium; and the argument seemed a good one. But the sea-level scheme involved a cutting which would have been 80 feet deeper than the Culebra Cut as now designed, and would have been carried also through many miles of alluvium which are not now being touched. I think the present experience with subsidence and humping in the Culebra Cut shows that a cutting to −40 feet through the Isthmus of Panama (involving a cut 574 feet deep at Culebra) would have been itself "a vast and doubtful experiment"—to make use of the Board's expression with reference to the Gatun Dam. The Board appeared to regard the making of an open cut as simply a question of yardage. It now appears that the depth is a factor which has to be reckoned with. I believe I am correct in saying that already the Culebra Cut is the deepest open cutting in the world. It has, therefore, already become to some extent an experiment. Inasmuch as few relatively comparable engineering works have been carried out in similar climates—combining great heat and high rainfall—it is the more experimental. How the rock itself at Gold Hill would behave if the Cut were carried from the present +95 feet to the −40 feet of a sea-level canal it is impossible to say; for the quality of the rock, which is so good at Bas Opispo where the Cut is shallow, gets worse as we approach Gold Hill, the deepest part of the excavation.

In the light of the experience of the last two years, I think the American Government have reason to be thankful that they did not undertake the sea-level canal, for it seems doubtful if it would ever have been finished. Had the troubles which have lately developed in the Culebra Cut been known beforehand, I think that it might even have been thought preferable to have a canal with a surface at about +110 instead of +85 feet, putting an additional lock at Bohio. With this level, and the original bottom width of 200 feet, the Culebra Cut would have probably caused but little trouble. The extra locks would have involved no new problems, and, when once committed to the necessary disadvantages of a high-level canal, it is not of capital importance whether there be six lockages or eight.

However, the present plan is not likely to be changed, and the Chief Engineer and Colonel Gaillard may be trusted to grapple with the wave slides with the energy and resourcefulness of which they have given so many proofs.

The Pacific Division.

This Division begins at Pedro Miguel and extends to deep water in the Pacific, a distance of about eleven miles. The original plan of the Commission involved a lock at Pedro Miguel and two locks, with large dams, at La Boca (now called Balboa), close to Panama. This plan was changed on the appointment of Colonel Goethals as Chief Engineer, partly on account of the character of the foundations for the proposed dams at La Boca, and partly on account of the position being exposed to gunfire from the sea. Miraflores, about two miles below Pedro Miguel, was accordingly chosen as the site for the lower locks. The work in the Division began much later than on the rest of the Canal, and the plan of the work as proposed in 1908 has since been modified. Lastly, the railway from Colon to Panama leaves the line of the Canal soon after passing Pedro Miguel. All these circumstances combine to make the Pacific Division less known to the public than the Atlantic and Central Divisions.

Coming from Culebra, the trough between the hills widens out and becomes lower as we approach Pedro Miguel, but the site of the single flight of locks is still so far confined by hills that no broad valley has to be dammed. The western dam runs for 1,700 yards from the lock wall backwards, almost parallel with the Canal, until it reaches the hills. The maximum head of water against it is 45 feet—*i.e.*, the whole depth of the water in Culebra Cut. East of the locks the ground is high enough to form a natural dam, but this is improved by a concrete core, as has already been explained. The single flight of two parallel locks at Pedro Miguel will lower vessels to Miraflores lake at the level of +54⅔. This small lake, about two miles long, receives no less than six rivers, four on the left bank and two on the right. These will supply water for the waste through the double flight of locks at Miraflores. Below Pedro Miguel lock is a concrete guide wall in the lake, and there is another in the lake above the Miraflores locks.

At Gatun, where all three locks are in series, there is only one guide wall, and the circumstance that all three locks are in a continuous

flight saves material in their construction Thus the separated locks of the Pacific end contain altogether 250,000 cubic yards more concrete than the contiguous locks at Gatun, although presenting a less imposing appearance.

The western dam at the lower end of Lake Miraflores projects forwards—*i.e.*, southwards—from the upper end of the locks for a length of 2,700 feet. It lies nearly parallel to, and near by, the western wall of the locks, and its southern end abuts on Cocoli Hill. The maximum head of water against this dam will be 45 feet. It rests on impervious material and is being constructed on the same principle as the Gatun Dam. It will be connected to Cocoli Hill and to the lock walls by a concrete core. East of the upper end of the Miraflores locks will be a concrete dam 500 feet long, which will form a spillway similar to that in the centre of the Gatun Dam. This will regulate the discharge of the six rivers which flow into Lake Miraflores. Below the double flight of two locks in series at Miraflores the Canal traverses swamps covered with vegetation for the next three and a half miles. The tides at the Pacific end of the Canal have an extreme range at Springs of 23 feet—*i.e.*, they rise 11½ feet above mean sea level. The surface of the swamps is below the high-water mark. Spoil from the Canal excavations is being spread over these marshes so as to raise the level of the ground sufficiently to prevent flooding, and in this way 450 acres will be reclaimed. This land, from its situation near the new port of Balboa and the proposed interior anchorage basin at the back of Sosa Hill, will be of great value and utility. The excavated channel of the Canal will here have a bottom width of 500 feet, and the calculated velocity of the tidal currents therein will be three-quarters of a statute mile per hour. In July the bottom was at -25 feet, but it had not yet been got out to full width. The five-mile sea channel from the docks to deep water is completed. The depth of the channel is 45 feet below mean sea level, which depth will be continued to the lowest lock at Miraflores. But the extreme range of the tides being, as already stated, 23 feet, there will be occasions on which the depth of water in this reach of the Canal may fall as low as 45 *minus* 11½—*i.e.*, 33½ feet. This, however, will never be for more than an hour or two, and the available depth for the greater part of every day will always be more than 40 feet.

The breakwater from the mainland to Naos Island is mainly to protect the Canal from the silt which drifts from the east, and formerly silted up the French canal somewhat rapidly. It is composed of rock from the Central Division. In places this has sunk, and humped up the sandbanks beside it.

A special feature of the Pacific Division is the hydraulic plant which has been erected below Miraflores. Earth excavation is to be done by means of a powerful water-jet from this plant instead of by steam-shovels.

The stone required for the concrete at Pedro Miguel and Miraflores is obtained from a quarry on Ancon Hill. Some Panamanians are employed on this work, for which they have an aptitude, and, altogether, some 250 to 300 are at work in the Pacific Division. Up to 1908 they were only employed for *machete* labour—*i.e.*, clearing bush and the like. Thus the presence of better industrial conditions seems to be slowly developing a capacity for better work among the natives. The dangerous work at heights on the locks is mostly done by West Indian negroes, who are fearless in this respect. Here they have shown themselves superior to the Spaniards. This is not the only indication provided by the last two years' experience that the negro labourer is likely to hold his own against the white navvy in the tropics.

The last feature of the work on the Pacific Division to which I need refer is the construction of scows for dredging, to avoid the voyage round Cape Horn. They are of reinforced concrete, which has a much longer life than wood in these latitudes, while being much cheaper than steel.

The metalled roads made by the Americans in the Canal zone have already produced an effect on the settlement of this fertile but empty territory. The land is taken up chiefly by coloured West Indians from Jamaica, Barbados and Martinique, who cultivate small patches and market the produce in the neighbouring towns of the zone, as, *e.g.*, Empire and Gatun.

The excellence of social and sanitary conditions on the Isthmus is maintained at the high level reached more than two years ago. After the Canal is opened on January 1st, 1915, the community which has gathered on the Isthmus will be much reduced, but there will still be a certain amount of work going on.

DISCUSSION.

The CHAIRMAN (Sir William H. White), in opening the discussion, said that the audience by their applause had signified their high appreciation of the paper to which they had just listened. He

endeavoured last year to secure the delivery of a lecture by the author at Winnipeg before Section G of the British Association meeting, but as Dr. Cornish could not undertake that labour the officials of the Association were fortunate enough to induce Colonel Goethals, the Engineer-in-Chief of the Canal, to read a paper on the subject. He thought those who had read that paper, which appeared in the Proceedings of the Engineering Section, would realise that everything that had been said by Dr. Cornish in regard to the conduct of such an enormously difficult engineering work was well deserved. It might not be known to many present that the engineers in charge of the Canal work were the engineer officers of the American Army, and it might seem strange to some people to notice that the Secretary of State for War of the United States was the Cabinet Minister in charge of the undertaking. The fact was, however, that, dating back from the early days of the Republic, the engineer corps of the Army had been in charge of the great public works of the United States, such as the improvement of harbours, which, in this country, were generally undertaken by private enterprise. At first the engineers put in charge on the Panama Canal were civilians, but for reasons into which he need not enter they were afterwards replaced by the engineer officers of the Army, and they were the men who, with civilian assistance, were now carrying out their gigantic task in such a wonderful way. Colonel Goethals sent his son, who had been on the works at Panama, straight to Winnipeg for the meeting of the British Association, and his appearance proved, if proof were needed, that, provided one lived in a proper and reasonable way, it was possible to be healthy on the Panama Isthmus. As Britishers, they rejoiced to think that the man who helped the American authorities to introduce the sanitary precautions which had attained such marvellous results in the preservation of life and health was their own countryman, Major Ronald Ross. He came home from the United States with Major Ross six years ago, when that gentleman was returning from Panama, and all the works of protection were in their infancy, and Major Ross told him, speaking on the basis of his large experience, that he was quite sure, with the precautions adopted, the Isthmus would become as healthy as any place need be. That forecast had been realised, because, as the author had stated, the death-rate was now only twelve in the thousand. There were one or two points in connection with the engineering side of the work to which he would venture to allude. First of all he desired to refer to the "slides" which the author had mentioned. There was no attempt to minimise those slides, and no fear of not being able to overcome the difficulties connected with them, as the following extract from the last annual report of the Isthmus Canal Commission up to the end of June last proved: "The total amount of material removed from all slides and breaks in the central division during the fiscal year amounted to 15 per cent. of the amount removed from the Culebra Cut." Speaking to the British Association at Winnipeg on the same subject, Colonel Goethals said: "There is only one way to deal with this, that is to remove the material." It was the very opposite of the Chat moss performance. The American engineers were not going to be stopped by anything. When men undertook to cut down into a mountain ridge to great depths, as the Americans had done at Culebra, they must face the unknown. All who had had to do with excavation, such as tunnel making, or any work of that nature, knew by experience that the crust of the earth was in a state of immense internal stress: and if anything was done to take away a part of the material which was helping to bear that stress, something which was unforeseen was likely to happen. Those who had seen the way in which, at the Simplon Tunnel, strong iron girders were crushed under the great depth of the mountain, after the Tunnel was formed, well knew that what was happening on the Panama Canal was not to be wondered at. He thought all engineers must admire the courage and endurance with which the American engineers faced such work. Even when great masses of rock were moved, and materials slid down, and the bottom humped up, as it was bound to do when the loads were so huge on either side of the cutting, the engineers did not complain; they simply went to work, as Colonel Goethals said, to "remove the materials," and they would go on doing it till they had completed their task. He quite agreed with the author's statement that the Canal would eventually be built. Mr. Taft, who had been concerned with the scheme throughout, had just visited Panama for the seventh time, and when he returned he stated that his confidence in the Canal being opened on January 1st, 1915, was still unabated. With regard to the nature of the works, it was useless to discuss any further the question of whether it would have been better to have had a sea-level canal or not. A lock canal was to be built, and the question to be considered was the scale of the work in relation to probable requirements. The author had stated that the locks were 1,000 feet long and 110 feet wide, and that there would be forty-eight lockages per day. The Americans believed that, while the Suez Canal could pass 21,000,000 tons in a year, 80,000,000 tons would be passed through the Panama Canal per year with forty-eight lockages a day. Of course, in a lockless canal like the Suez, the question of the length of the vessel did not arise, the draught being the important question which then had to be considered. He believed the draught of the Suez Canal was now down to eleven metres, and he understood the engineers were aiming at a thirty-six feet draught. The Panama Canal, however, would have forty-one feet of water, and he could not help thinking that the depth over the lock sills had been made forty-five feet, not merely to provide for possible want of water, but also, if there was sufficient water, to enable a still greater draught to be obtained in the canal, because it would not be an easy thing to alter the lock

entrances and to increase the depth over the sill. Forty feet was about the greatest depth that was now contemplated in the approaches to the great harbours of the world. The Ambrose Channel at New York was now giving forty feet, and the greatest depth at which ships were now being worked was about thirty-four feet. In the Suez Canal, where the ships travelled slowly, they always required about eighteen inches of water under their keels. The dimensions of the locks at Panama would amply suffice for any ship either in existence or planned. Contrary opinions existed as to whether ships would, in the future, exceed 1,000 feet in length. Time would show which opinion was correct, but ships had a strange habit of growing. He had no doubt that the commercial side of the matter would determine that question. Probably those present understood the importance of the point made by the author that, although the locks were 1,000 feet long, they could be shut off into sections. The gates were so arranged as to give lengths of 550 feet and 350 feet in the locks, and in that way either section could be used to diminish the quantity of water required for lockage. An important point to bear in mind in that connection was the fact referred to in the last report which Colonel Goethals made, that 95 per cent. of the sea-going vessels of the world at the present time were less than 600 feet long. The difficulties upon which he had touched were only a few of those which all people felt their American relatives had faced, and were overcoming, in one of the most gigantic engineering problems which the world had ever witnessed; and he was sure all Britishers wished them "God-speed" in the endeavour to bring the undertaking to a successful conclusion.

Mr. J. A. Saner said he desired to confine his remarks to one or two points, which, as an engineer, struck him as being of great interest. In the first place, he noticed that the Americans had reduced the top water level of the canal from the original design. Mr. Ford read a paper in 1900 before the Institution of Civil Engineers in which it was stated that the summit level of the Canal would be ninety-five feet above mean sea level. In the discussion which followed the paper, he (Mr. Saner) suggested that it would be well to leave out the summit locks; and from the section given by Dr. Cornish he noticed that the Americans had reduced the level of the upper water to 62 feet above datum, and had done away with two or three of the locks. That was a most important point in considering the difficulty of navigating large vessels through locks of any kind, and the alteration made was, he thought, a very great improvement in the design of the Canal. The author stated in the paper that it was intended to leave the whole of the vegetation in the huge lake which was being formed, with the exception of the width of the canal itself. Although it must be an almost impossible piece of work to remove 164 square miles of forest, it appeared to him that that vegetation would constitute a serious source of danger, in two ways. First of all, the timber would no doubt decay and be washed down by the floods into the channel of the Canal, and it was always a bad thing for a navigable channel to be subjected to floating timber. Not only did the timber get sodden with water, so that it was just afloat, but it lay in the bottom of the Canal; and his experience of the River Weaver was that a large number of propellers were broken through the semi-floating, and almost submerged, timber which came down from the tributaries. That, it seemed to him, was a difficulty which would have to be dealt with when the time arrived. It also appeared to him, that, with the decay of the timber, a malarial swamp would again be formed. Anything like 160 square miles of decaying timber must be a source of danger to health as well as to navigation. Another very interesting point which the chairman had mentioned, was the sliding of the banks of the deep cuttings. Engineers knew that there was a natural slope for each different kind of earth, which it would assume sooner or later after being cut into. It might not assume that natural angle of inclination immediately, the probability being that even very soft earth would stand almost vertical for some time; but as soon as the weather attacked the open cutting the earth gradually assumed a natural slope, which varied with every kind of earth. In some cases there was a slope of 1 in 5; in others 1 in 6, or 1 in 10; and sometimes it would be very nearly vertical. The American engineers appeared to have realised that fact in the making of the Gatun dam, where they had adopted a very easy slope of 1 in 10. He thought as they went on into the deep cutting they would gradually find out what the natural slope of the particular rock was at each particular place. He noticed that in the photographs shown of the deep cutting, where it was in hard rock the sides were standing nearly vertical, and that the slides took place at each end of the cutting, where there was a change in the nature of the rock, and the rock was not solid. He could not help feeling that the people of this country were rather afraid of tackling the question of canals. Some papers were read before the Society in 1888 on the importance of canals in this country, one of which he had the honour of writing himself. From that time very little was done up to five years ago, when a Royal Commission was appointed which reported on the feasibility of improving the canals of the country. He did not desire that Commission's report to be entirely shelved, but hoped England would follow the example of their American brethren, and improve their canals in the way that was being done on the other side of the Atlantic.

Mr. R. St. George Moore said that two months ago he had the pleasure of spending four days on the Isthmus of Panama, and during the whole of

that time he was not once bitten by a mosquito. The climate appeared to him infinitely better and more pleasant to live in than in Singapore. With regard to the question of a sea-level versus a lock canal for Panama, careful investigation of the conditions that obtained there appeared to him to point to the fact that the American engineers were absolutely right in building the kind of canal they had adopted. The first reason for that assertion was the difference of level between the two oceans; to attempt by lock gates to control an ocean seemed to him a very large order. In the second place, there were ample head-waters. The engineer in charge of the Gatun dam informed him that not only did the engineers anticipate having ample water for the working of the locks, but they thought there would be a sufficient water supply for lighting the whole of the Canal from end to end. The engineers stated that they did not anticipate there would be any necessity to economise water, but if it was found necessary to do so, by an arrangement of inlets and outlets to the dual locks the one lock could be utilised as a reservoir basin for the other. The large lake also formed a safety-valve for the tropical rainfalls. The third important point was that, instead of having a canal only 300 feet wide throughout its entire length, by means of the scheme adopted a canal would be built, sixteen miles of which were 1,000 feet wide.

Mr. J. G. Leigh emphasised the readiness with which the American Government and the American officials placed every detail connected with the construction of the Canal at the disposal of journalists, a plan which many English manufacturers might copy with advantage. In the course of his literary work he had been forced to obtain from the State department at Washington, or from manufacturers in America, information about English manufactures and enterprise which he had been unable to obtain in this country. The fact could not be sufficiently emphasised that the minimum width of the Canal only extended through the cutting, and that in its other parts it varied between 500 and 1,000 feet.

Dr. Vaughan Cornish, in reply, said the experience of the last two years enabled one to form an opinion as to whether it would have been better to adopt a sea-level or a high-level canal, an opinion which he was not able to decide to his own satisfaction two years ago. He thought the American Government were to be congratulated on the fact that they did not embark upon a sea-level canal. To have done so would have necessitated carrying the cutting down eighty feet lower, from plus forty feet to minus forty feet, so that at Gatun there would have been a hill more than 500 feet high towering over the cutting. How that rock might have behaved, with the possible stresses which might come upon it, and the rapid disintegration which basalt rock was liable to undergo, particularly in a hot climate, it was impossible to say. The trouble from slides would have been endless if it had been necessary to continue the cutting, not only through the eight miles of basalt rock, but through the thirty-two miles of alluvial earth; and he very much doubted if the patience of the American nation would have lasted out till the completion of the work. There would have been no end to the work, and it might have been abandoned before it was completed. The slides which had taken place had practically settled the question as between a sea-level and a high-level canal in favour of the latter.

On the motion of the Chairman, a hearty vote of thanks was accorded to the author for his interesting and instructive paper, and the meeting terminated.

FOOD CONSUMPTION IN PARIS.

In Paris, dealers in horse and mule meat are compelled by law to indicate, by means of a sign of a horse's head over the front of their places of business, the nature of their trade. This is to protect the unsuspecting public, who frequently are unable to distinguish between beef and horse meat. According to reliable statistics quoted by the American Consul in the French capital, Paris consumes in a year 347 million pounds of beef, veal, and mutton. To this must be added 79 million pounds of pork and nearly 9 million pounds of pork products. In these pork products are included the sausages and various preparations and mixtures of meat. In addition to this, the consumption of horse and mule meat is large. In fact, each year over 29 million pounds of horse and mule meat are consumed, representing about 61,000 animals. The total amount of meats of all kinds consumed annually in Paris reaches the significant figure of 455 million pounds. The amount of poultry eaten in Paris annually reaches 48 million pounds. The consumption of game attains 3 million pounds. Large numbers of rabbits are also fed and fattened for the market, and form a considerable quantity of food. That the Parisians are also great fish eaters is shown by the number of pounds sold annually, as follows: Salt-water fish, 87 millions; fresh, over 6 millions; smoked, 343,000; salted, 22,000. Total, 94 million pounds. Oysters, mussels, shellfish generally, and snails, also find numerous eaters, for their consumption is relatively important — 25 million pounds, in addition to over 1 million pounds of snails and crawfish. The consumption of vegetables in Paris reaches the following figures: —General vegetables, 31 million pounds; mushrooms, nearly 9 millions; and watercress, 13 million pounds. As to butter and eggs, Paris consumes of the former annually, 33 million pounds, and of the latter, 55 millions, and this, notwithstanding the fact that both these products command throughout the year an extremely high price, and are principally obtained from the pro-

vinces. Of late years Paris has been consuming many eggs imported from Germany, which country in turn buys from Russia, England, Italy, and America. The consumption of fruit reaches 46 million pounds annually. All fruit in Paris is sold by weight, the lowest in price being 2½*d.* per pound, and ranging from that figure to 1*s.* 8*d.* per pound. Bananas always command a high price, and are of inferior quality. As to cheese, which is never excluded from a meal in France, the annual consumption reaches over 37 million pounds, and is divided among the following kinds:—Camembert, 21 millions; Brie, 6 millions; Coulommier, 4 millions; Livarot, 2 millions; Gruyère, 2 millions; Mont Dore, 500,000; Port Salut, 260,000; Roquefort, 68,000; Contal, 62,000; Munster, 62,000; and other kinds, 2 millions.

HOME INDUSTRIES.

The Distington Explosion.—More than a year ago a remarkable boiler explosion occurred at the Distington Iron Works in Cumberland. It was one of the rare compound-boiler explosions. Of eleven Lancashire boilers in a battery, four were destroyed, and three others partly torn open. The *débris* were scattered over an area half a mile across. The Board of Trade has just issued its report. One would have thought that it might have been issued more expeditiously, for it is fourteen months since the accident occurred—but perhaps better late than never. The evidence shows that probably No. 7 boiler exploded by excessive pressure, and by the force of the explosion caused three others on its flanks to explode almost simultaneously. No. 7 had been laid off for cleaning, and it seems that an iron plate had been inserted in the pipe between the boiler and the stop-valve connecting the boiler to the steam-range, so as to keep steam from leaking into the boiler and inconveniencing the men inside. The safety-valve and the stop-valve were, however, on the two legs of a Y pipe, so that the iron plate would both cut the stop-valve and the safety-valve off from the boiler. Apparently, after cleaning, it was forgotten to remove this iron plate, so that when the steam was raised the safety-valve would be out of action and the opening of the stop-valve would not supply any outlet for the steam, but would, on the other hand, permit steam from the other boilers to have access to the safety-valve of No. 7. Hence a slight leakage at this safety-valve, or its blowing-off owing to the pressure in the steam-range, would make the attendant suppose that the safety-valve of No. 7 was in proper action, although the pressure in No. 7 might be much higher than in the others. It would seem that this is what happened, the pressure in No. 7 rising until the explosion occurred.

Folded Woven Goods.—In deference to representations made by Manchester firms, the Government of Southern Nigeria have decided to introduce into the Legislative Council a Bill to amend the Folded Woven Goods Ordinance of the Colony. The Bill will permit certain variations in the way of folding certain goods to meet the requirements of the trade in such goods, and to consolidate the various amendments now existing to that Ordinance as originally passed. The Bill contains a schedule of exempted articles which differs from any previous one. The Ordinance is to take effect as from January 1st.

The Price of Glycerine.—Reference was made in these Notes recently to the great advance in the price of glycerine, and since then there has been further rise. Chemically-pure glycerine is now over £100 per ton. The *Manchester Guardian* gives some interesting facts respecting this industry. The prices of chemically-pure glycerine are regulated by two conventions, one embracing British makers and the other Continental makers. These act independently of each other as regards prices, but they have a working agreement as to the limitation of competition in their respective spheres. The British production amounts to about 13,000 tons per annum, the French to 14,000 tons, the German to 9,000 tons, the Spanish and Italian together to 4,000 tons, and American manufacturers produce about 20,000 tons, in addition to which quantities ranging from 12,000 tons to 19,000 tons are annually imported from Europe. The great advance in prices is due to a very exceptional combination of circumstances. On the one hand the costs of production have been increased owing to the supersession of glycerine-yielding tallow by paraffin wax on the part of soap manufacturers, and the very high price of soap-making oils has tended to limit their use and divert the demand to non-glycerine yielding fats. Then there has been a large increase in the demand for high explosives owing to the many large constructive undertakings in progress, and the great expansion that has taken place in the mining industry. Probabilities point to the present high level of values being maintained for a considerable time.

New Engineering Works.—The number of new engineering works to be promoted by Bills or Provisional Orders in the next session of Parliament point to proposed improvements and extensions of existing undertakings of much importance, more especially in the case of railways and tramways, and river, dock, water, and drainage works. Amongst new railways and improvements may be mentioned the proposal of the Metropolitan Railway for a widening of the line and the construction of a new station at Mount Pleasant, between Farringdon Street and King's Cross stations. The Tilbury and Southend Company is asking for extended electrical powers, including the construction of generating stations, and the Great Northern wants to widen at Finsbury Park, as well as other parts of its system, particularly through Peterborough and from Doncaster northwards to the junction with the North-Eastern

Railway. The Midland is projecting a new direct overhead line through Bradford to take the place of the direct line sanctioned in 1898. It is also proposing new lines in connection with the King's Dock at Swansea. The North-Eastern line is promoting a widening of its Leeds and Selby Railway, with various road works in Leeds and four short railways in the Newcastle district. There are two railway proposals by new companies, and new railways are being promoted by the Manchester Ship Canal Company, and by the Great Yarmouth Port and Haven Commissioners in connection with new dock and other works. There are sixteen notices of Bills or Provisional Orders dealing with new tramways or extensions, besides the very large programme of the London County Council; power to run omnibuses and other road vehicles is being sought by several railways and corporations, and there are numerous schemes for trackless trolleys, or railless overhead electric traction. The Corporation of London is seeking power to construct a new bridge over the Thames between Blackfriars and Southwark bridges, and to rebuild Southwark bridge. The most important dock scheme is that of the Clyde Navigation Trustees.

British Industries at Turin.—The British Industrial Court at the Turin Exhibition of next year promises to be a thoroughly representative display of the various industries of the United Kingdom. It is hoped that the very successful British display made by the chemical manufacturers of Great Britain at the Brussels Exhibition of this year will be improved upon. The Chemical Industries Committee of the British Royal Commission is already considering the matter, and at the meeting of the Association of Chambers of Commerce of the United Kingdom it was resolved that "in view of the success which has attended the collective exhibits of the Chambers of Commerce at the Brussels Exhibition, and their effectiveness in directing attention to the staple industries of this country, the Association strongly recommends all the Chambers representing manufacturing industries to organise collective displays of their products, in addition to the industrial exhibits of their members, for the Turin Exhibition to be held next year."

The Consumption of Whisky.—The annual reports of the Inland Revenue, now for the first time included in the first report of the Commissioners of His Majesty's Customs and Excise, includes tables which point to a great diminution in the amount of spirits retained for consumption in the United Kingdom in the fiscal year ended March 31st last. It was only ·48 proof gallon per head of the population, as against ·72 in the previous year, and ·89 in 1901. The proportions given for Scotland are ·94 last year against 1·38 in the previous year, and 1·68 in 1901. These figures point to an immense reduction in consumption of whisky; but it must be borne in mind that they apply not to the actual consumption, but to the quantity retained for consumption—that is to say, the quantity held as well as the quantity sold. And, naturally, dealers reduced their stocks when the duty was raised. The whisky trade has been paralysed by the last two Budgets. Over-production had left it in a very depressed condition for some years before the 1909 Budget, but the imposition of the additional 3*s.* 9*d.* duty has seriously worsened the position by checking consumption.

South American Wool.—To-day South America ranks second as the producer of wool, but in many parts the difficulty in getting the raw material to shipping centres at reasonable cost is great, and will remain so until railway systems have been developed. The Bradford spinners and manufacturers do not like South American wools owing to their not working up as soft as similar wools from New Zealand. But River Plate cross-breds have shown improvement in recent years, and the *Statist*, which has an interesting article on the subject in its last week's issue, argues that there is no good reason why larger quantities of South American wools should not be used by our home-trade manufacturers, although it is a well-known fact that the produce from both Uruguay and the Argentine does not spin so well as the wools grown in Australia and New Zealand.

The Petrol Tax and Commercial Motors.—A meeting of makers and users of commercial motors was held in London last week, with the object of doing all that is possible to get the petrol tax removed. The meeting was very representative of the trade, since persons employing 40,000 men and paying 90 per cent. of the tax were present. Their case would seem to deserve the careful attention of the Government. The argument is that the tax is retrogressive; that it puts unnecessary difficulties in the way of cheap transport; that the petrol-driven vehicle is tyred with rubber and does the least damage to the road; and that to tax one form of traction is unfair. The effect of the tax on the industry is said to be very injurious.

OBITUARY.

Archibald Scott.—The death took place on the 6th inst., at his residence, South Bank, Surbiton, of Mr. Archibald Scott, in his 91st year.

Mr. Scott was appointed traffic manager of the London and South-Western Railway in 1852, and held that position until 1870, when he became general manager. On retiring from the latter office in 1885 he became a director of the company, a position which he held till his retirement in 1902. He became a member of the Royal Society of Arts in 1888.

NOTES ON BOOKS.

MODERN BUSINESS TRAINING. By John King Grebby. London: Macdonald and Evans. 3s. 6d. net.

Mr. Grebby has acted as Examiner for the Society in the subject of "Handwriting and Correspondence" since this subject was first added to the list in 1901, for he was associated in that year with Sir Courtenay Boyle, and on Sir Courtenay's death he undertook the whole of the work. He will now examine in the new subject, "Business Training," which appears for the first time in the Programme for the present year.

It may therefore be taken that he has considerable knowledge, both of the qualifications and the deficiencies of young students preparing for a commercial career, and that he is quite competent to give them useful advice and instruction. The number of such students is increasing year by year. The education for the most part provided in our primary and lower secondary schools is adapted to the wants of youthful clerks and of no other class, and the natural tendency of boys to prefer clerical to manual work is fostered and increased by their school training.

This being so, it appears desirable that the special technical training which will help boys to attain the object of their ambition should be provided, and that boys should not be left, as of old, to pick up by practice in an office the routine and method of the particular business which they may have entered. Classes, text-books and examinations are all needed, and have all been provided, and it may reasonably be expected that, on the one hand, the early work of the junior clerk may be made easier, and, on the other, that he may more quickly become capable of rendering useful service to his employer.

The field of study is a wide one, since it of necessity includes every department of trade and commerce, and though the elementary work in most offices is very similar, it soon becomes specialised, and the lad gets on most rapidly who can adapt himself to the specialities of his particular business. Hence a handbook on business training, after a general division applicable alike to all clerical work, must soon branch off to the treatment of special lines of industry. This Mr. Grebby has done. He treats not only of "goods sold and delivered," with the various devices incidental to such sale and delivery, but also of customs and excise, railways, banking, insurance, companies, the Stock Exchange, etc. The junior, and indeed the senior, clerk in each and all of these various divisions of commerce will find much of value and of practical service to him in these pages.

QUANTITY SURVEYING. By George Metson. London: John Dicks Press, Ltd. 6d. net.

This little volume is composed of material which originally appeared in the *Illustrated Carpenter and Builder*. The author is a teacher of Builders' Quantities and Building Construction at the Borough Polytechnic Institute, and his practical experience enables him to judge what his pupils ought to know and how they should learn it. He is of opinion that all building students, whether their intention is to become architects, builders, or foremen, should study quantity surveying; and there can be no doubt, as he says, that although the professional quantity surveyor fills a recognised and useful place in the building world, it is desirable that the architect and builder should know something of his work, even if it be only for the purpose of checking it. The book, which appears to be very concise and clear, will be welcome to many, not only for its excellence but for its cheapness. Hitherto it has only been possible to study the subject in comparatively expensive volumes.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANACK, 1911 (Jubilee Issue). Edited by George E. Brown, F.I.C. London: Henry Greenwood and Co. 1s. and 1s. 6d. net.

This well-known book of photographic reference has now reached its jubilee number. It commenced in 1860 with a wall or street calendar. Then there were five numbers of a pocket-size volume, and since 1866 it has appeared in its present form, though it has grown from a very slim book into one over 2¼ inches thick. Of this bulk just two-thirds are advertisements, but these advertisements are by no means the least useful part of the book. The "reading matter" comprises all sorts of tables and formulæ for photographers, with other miscellaneous information, besides including a very complete record of the photographic progress of the year.

GENERAL NOTE.

SUNFLOWER-GROWING IN RUSSIA.—The sunflower is grown in Russia to a considerable extent, the amount of seed crushed exceeding annually half a million tons. At first the centre of its cultivation was in the Provinces of Tchernigov, Kief, Poltava, and Kharkov, but now the principal cultivation of the plant has moved further south-east into the Province of Stavropol. Much of the seed is eaten either raw or roasted. The bulk of the seed, however, is pressed for its oil, which finds a ready sale as a welcome Lenten fare. Since the introduction of improved methods of refining, a very palatable oil, with a clear and pleasant yellow tint, has been produced. As a rule it is shipped in ordinary wooden casks, although lately tin canisters have been used successfully. Small shipments have been made as an experiment, and, strange to say, to such parts of the Mediterranean as are famous for their production of olive oil—its use probably being for the consumption of the people there, while the more valuable olive oil is found more profitable to export.

MEETINGS OF THE SOCIETY.

Ordinary Meeting.

Wednesday evening, at 8 o'clock :—

December 14. — Reginald A. Smith, B.A., F.S.A., "A New View of Roman London." George Laurence Gomme, F.S.A., will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock :—

December 15.—Robert Fellowes Chisholm, F.R.I.B.A., F.S.A., "The Taj Mahal and its Relation to Indian Architecture." Sir William Lee-Warner, K.C.S.I., Chairman of the Indian Section Committee, will preside.

Cantor Lecture.

Monday Evening, at 8 o'clock :—

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Industrial Pyrometry." Four Lectures.

Lecture IV.—December 12.—Radiant energy—The "fourth-power" law—Laws of Wein and Planck—The Féry radiation pyrometers and indicators—The Holborn-Kurlbaum optical pyrometer—Wanner's pyrometer—Other optical pyrometers—Special uses of radiation pyrometers in pottery manufacture and work at very high temperatures.

Papers to be read after Christmas :—

Horace M. Wyatt, "Motor Transport in Great Britain and the Colonies."

Philip Joseph Hartog, M.A., B.Sc., "Examinations and their bearing on National Efficiency."

J. C. Medd, "The Dutch Labour Colonies."

Cyril Davenport, "Illuminated Manuscripts."

George A. Stephen, "Modern Machine Bookbinding." John Murray will preside.

Professor J. Wertheimer, B.Sc., B.A., "Water-Finders."

Captain A. J. N. Tremearne, "Some Nigerian Head-Hunters."

Hon. Sir Richard Solomon, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "South Africa before and after the Union."

F. Douglas Osborne, M.Inst.M.M., "The Tin Resources of the Empire."

Reginald Murray, "Indian Banking."

R. A. Leslie Moore, I.C.S. (retd.), "Indian Superstitions."

Captain R. Muirhead Collins, C.M.G., "Australia and her Resources."

Frank M. Andrews, "Architecture in America."

Arthur Charles Davis, F.C.S., Assoc.Inst.C.E., "The Manufacture and Testing of Portland Cement."

George B. Heming, "Art Education in Jewellery and Goldsmithing."

Colonel Charles Edward Cassal, V.D., F.I.C., "The Adulteration of Food."

Dr. Leonard Hill, F.R.S., "Caisson Sickness and Compressed Air."

Sir William Abney, K.C.B., D.C.L.. D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

Hal Williams, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

Noel Heaton, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

Indian Section.

Thursday afternoons, at 4.30 o'clock :—

January 19, February 9, March 16, April 27, May 25.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock :—

January 31, February 28, April 4, May 9.

Cantor Lectures.

Monday evenings, at 8 o'clock :—

Frederick Wedmore, "Etching": 1. "The Old Masters;" 2. "Modern Etching." Two Lectures.

January 23, 30.

Professor Adrian J. Brown, M.Sc., "Brewing." Four Lectures.

February 6, 13, 20, 27.

Professor J. A. Fleming, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

March 6, 13, 20, 27.

Alfred E. H. Tutton, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

Juvenile Lectures.

Wednesday evenings, January 4 and 11, 1911, at 5 o'clock :—

Professor Arthur Mason Worthington, C.B., M.A., F.R.S., "A Study of Splashes, conducted by the aid of Instantaneous Photography." Two Lectures.

MEETINGS FOR THE ENSUING WEEK.

Monday, December 12...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. C. R. Darling, "Industrial Pyrometry." (Lecture IV.)

Mechanical Engineers, Storey's Gate, Westminster, S.W., 8 pm. (Graduates' Section.) Mr. J. C. Briggs, "Workshop and Factory Lighting, with a Special Reference to the Use of High-Pressure Gas."

Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Mr. W. A. Riley, "The Manufacture of Aerated Waters."

Surveyors, 12, Great George-street, S.W., 4 p.m. Mr. Robert M. D. Sanders, "The Organisation of Agricultural Credit under Land and Local Credit Societies."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. H. Beaumont, "Ruskin's Bible of Amiens."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. G. L. Elkington, "That Foreign Travel and Study retard the Development of a National Style."

TUESDAY, DECEMBER 13...Sociological (at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8.15 p.m. Dr. J. Lionel Tayler, "Sociology and its Racial Applications."

Faraday Society (at the Institute of Electrical Engineers, Victoria Embankment, W.C.), 8 p.m. 1. Mr. James Swinburne, "Separation of Oxygen by Cold." 2. Dr. Henry J. S. Sand and Mr. William M. Smalley. "New Apparatus for the Rapid Electro-analytical Determination of Metals."

Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. H. W. Codrington, "The Kandyan Constitution."

Optical (in the Chemical Society's Rooms, Burlington House, W.), 8 p m. Mr. C. F. Lan Davis, "The Theory of the Iris Diaphragm."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. H. K. G. Bamber's paper, "Portland Cement, and the Question of its Aeration."

Photographic, 35, Russell-square, W.C., 8 p.m. Professor E. J. Garwood, "Two Summers' Exploration in Spitzbergen."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Dr. W. E. Hoyle, "The Report of the International Commission on Zoological Nomenclature presented to the Graz Meeting of the International Zoological Congress, 1910." 2. Mr. E. S. Goodrich, "On the Segmentation of the Occipital Region of the Head in the Batrachia Urodela." 3. Dr. W. N. F. Woodland, "On the Structure and Function of the Gas-Glands and Retia Mirabilia associated with the Gas-Bladder of some Teleostean Fishes, with notes on the Teleost Pancreas." 4. Mr. Oldfield Thomas, "The Mammals of the Tenth Edition of Linnæus: an Attempt to fix the Types of the Genera and the exact Bases and Localities of the Species."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. General Sir J. Bevan Edwards, "The Necessity for an Imperial Parliament."

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m. 1. Mr. C. A. Hill, "Note on the Crystallization of Sodium Salicylate Solution." 2. Mr. John C. Umney, "A Triangular Contest in Peppermint Oils." 3. Mr. E. M. Holmes, (a) Note on the Sleeping Sickness Fly and Tsetse Fly"; (b) "Note on Truxillo Coca."

WEDNESDAY, DECEMBER 14...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. R. A. Smith, "A New View of Roman London."

Automobile Engineers (at the Institute of Mechanical Engineers, Storey's Gate, Westminster, S.W.), 8 p.m. Dr. W. Watson and Mr. R. W. Fenning, "The Efficiency of the Two-Cycle Motor."

Engineers, Junior Institution of (at the Royal United Service Institution, Whitehall, S.W.), 7.30 p.m. Mr. G. L. Kothny, "Some Recent Developments in Condensing Plant."

United Service Institution, Whitehall, S.W., 3 p.m. Mr. W. H. St. John Hope, "The Strategical Aspects of English Castles."

THURSDAY, DECEMBER 15...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. R. F. Chisholm, "The Taj Mahal and its Relation to Indian Architecture."

Royal, Burlington House, W., 4.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Dr. Otto Stapf and others, "Reports on the International Botanical Congress at Brussels, 1910." 2. Mr. R. W. H. Row, "Non-Calcareous Sponges from the Red Sea, collected by Mr. Cyril Crossland." 3. Mr. R. S. Adamson, "Comparative Anatomy of Leaves of Veronica."

Chemical, Burlington House, W., 8.30 p.m. 1. Drs. H. E. Armstrong and E. F. Armstrong. "Studies on enzyme action. Part XV. The comparative influence of monohydric C_nH_{2n+1} alcohols and other non-electrolytes on enzymic activity." 2. Drs. H. E. Armstrong, E. F. Armstrong, and E. Horton, (a) "Studies on enzyme action. Part XVI. The enzymes of emulsin (II). Prunase." (b) "Studies on enzyme action. Part XVII. The enzymes of emulsin (III). The probable seat of origin of amygdalin." (c) "Studies on enzyme action. Part XVIII. Enzymes of the emulsin type (II). The distribution of β-glucases in plants." 3. Drs. H. E. Armstrong and J. V. Eyre, "Studies on enzyme action. Part XIX. Enzymes of the emulsin type (III). Linase." 4. Messrs. W. H. Hurtley and W. O. Wootton, "The interaction of alloxan and glycine." 5. Mr. W. R. G. Atkins, "Traube's molecular volume method applied to binary mixtures of organic substances." 6. Messrs. R. H. Pickard and J. Kenyon, "Investigations on the dependence of rotatory power on chemical constitution. Part I. The rotations of the simplest secondary alcohols of the fatty series." 7. Messrs. J. J. Dobbie and A. Lauder, "Oxycodeine: a new alkaloid from opium."

London Chamber of Commerce, Oxford-court, Cannon-street, E.C., 4.15 p.m. Mr. W. Barnes Steveni, "Commercial Resources of Russia."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. M. Phillips, "Lore, Legend, and Life 'twixt Tyne and Tweed."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. T. C. Porter, "Stereoscopy with a Long Base Line."

Philatelic, 4, Southampton-row, W.C., 6 p.m. Mr. M. P. Castle, "Notes on the 1853 Issue of British Guiana, with Display."

Historical, 7, South-square, Gray's Inn, W.C., 5 p.m. Rev. J. Neville Figgis, "Respublica Christiana."

Numismatic, 22, Albemarle-street, W., 6.30 p.m. 1. Mr. H. Symonds, "The Trial of the Pyx, etc., under Charles I." 2. Mr. J. G. Milne, "Alexandrian Tetradrachm of Tiberius."

Concrete Institute (at the Royal United Service Institution, Whitehall, S.W.), 8 p.m. Mr. T. Potter, "General Concrete Practice."

Architects, Society of, 28, Bedford-square, W.C., 8 p.m. Mr. G. A. T. Middleton, "A Great London Improvement Scheme."

FRIDAY, DECEMBER 16...Geographical (in the Theatre, Burlington Gardens, W.), 8.15 p.m. Professor P. Geddes, "Inland Towns and Cities: their Main Origins." (Lecture I.)

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7.30 p.m.

Brewing, Institute of (Yorks and N.E. Section), Queen's Hotel, Leeds, 8 p.m. Mr. Otto C. Overbeck, "The Discovery of the Chemical Production of Alcohol in Fermented Beer in the Absence of Yeast."—(Scottish Section.) Caledonian Station Hotel, Edinburgh, 7.30 p.m. Dr. J. Horne, "The Water-Bearing Strata of the City of Edinburgh."

Mechanical Engineers, Storey's Gate, Westminster, S.W., 8 p.m. 1. Professor H. C. H. Carpenter and Mr. C. A. Edwards, "The Production of Castings to withstand High Pressures." 2. Mr. A. McCance, "The Constitution of Troostite and the Tempering of Steel."

Civil Engineers, Great George-street, S.W., 8 p.m. (Students' Meeting) Mr. R. N. Mirza, "Mathematical Deduction of the most Economical Ratio of Reinforcement for Reinforced-Concrete Structures."

Journal of the Royal Society of Arts.

No. 3,030. VOL. LIX.

FRIDAY, DECEMBER 16, 1910.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

CANTOR LECTURES ON "INDUSTRIAL PYROMETRY."

On Monday evening, the 12th inst., Mr. CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., delivered the fourth and last lecture of his course on "Industrial Pyrometry."

On the motion of the Chairman, a vote of thanks to Mr. Darling for his course was carried unanimously.

The lectures will be published in the *Journal* during the Christmas recess.

INDIAN SECTION.

Thursday afternoon, November 15th; Sir WILLIAM LEE-WARNER, K.C.S.I., in the chair. A paper on "The Taj Mahal and its Relations to Indian Architecture" was read by Mr. ROBERT F. CHISHOLM, F.R.I.B.A., F.S.A.

The paper and discussion will be published in a subsequent number of the *Journal.*

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 4th and 11th, at 5 o'clock, by ARTHUR MASON WORTHINGTON, C.B., M.A., F.R.S., Professor of Physics in the Royal Naval Engineering College, Devonport, on "A Study of Splashes, conducted by the aid of Instantaneous Photography."

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Members who desire tickets for the course are requested to apply for them at once.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FIFTH ORDINARY MEETING.

Wednesday, December 14th, 1910; GEORGE LAURENCE GOMME, F.S.A., in the chair.

The following candidates were proposed for election as members of the Society:—

Borthwick, Miss Jessica, 33, Rue du Jardin, Ostend, Belgium.
Eastburn, Mrs. Adelaide, 14, Ravenscourt-mansions, Hamlet-gardens, Ravenscourt-park, W.
Haslehust, Ernest W., 72, Burnt Ash-hill, Lee, S.E.
King, Alexander Freeman, C.B., 44, Foxgrove-road, Beckenham.
Miles, George W., 29, Central-street, Boston, Massachusetts, U.S.A.
Mylcrist, Captain Stanley, 560, Sunder-road, Karachi, India.
Wigram, Reginald, J.P., M.Inst.C.E., Chapel Allerton, Leeds.

The following candidates were balloted for and duly elected members of the Society:—

Briggs, Miss Irlam, Milnthorpe, Parkstone, Dorset.
Cooper, Alfred Heaton, May Field, Ulverstone, Lancashire.
McDonald, Thomas J., Assoc.M.Inst.C.E., Mansfield, Arrochar, Loch Long, N.B.
Mitchell, Hawthorn, 39, Mecklenburgh-square, W.C.
Murray, Reginald, 12, Bedford-row, W.C.
Power, John Cecil, 1, Queen's-ride, Barnes Common, S.W.
Sotham, Bernard, c/o Messrs. Lynch, Teheran, Persia, and The Priory, Iffley, Oxford.
Stanley, William Neems, 12, Spencer-road, Cottenham Park, Wimbledon, Surrey.
Wheeler, R. Vernon, D.Sc., The Colliery House, Altofts, Yorkshire.

The paper read was—

A NEW VIEW OF ROMAN LONDON.

By Reginald A. Smith, F.S.A.

At the present day little excuse is needed for introducing to a London audience any new evidence with regard to town-planning and traffic regulation; for though the present paper deals with London as it was nearly two thousand years ago, it is meant to illustrate the manner in which the engineering genius of Rome laid down the main lines of traffic in this part of Britain, before the spread of bricks and mortar made the problem well-nigh insoluble. The scope of this Society is large, but as its avowed aims do not include ancient history, geography, or archæology, it will be fitting to lay special stress on the Roman plan of London and to introduce as little as possible of the archæological evidence on which that plan is and can alone be based. A general knowledge, therefore, of the principal dates and incidents in the invasion and conquest of this island by Rome will be assumed, and particular attention directed to the history and arrangement of the main roads. The minor streets are now hopelessly lost, and do not seem to have coincided with any existing thoroughfares, many of these having been proved by excavation to have been crossed by buildings.

Those who desire a closer acquaintance with the archæological data are referred to the first volume of the "Victoria History of London," where for the first time the available published evidence has been brought together, examined and arranged, under the general editorship of Mr. Wm. Page. As a contributor I cannot dilate on the importance of this volume, which contains enough material for many divergent views of Roman London and will, no doubt, give rise to other works on the subject; but as my text is there in black and white I may, on the present occasion, deal with it in a less formal manner, and possibly present my conclusions more forcibly to an audience already familiar with the locality.

Britain was in contact with Roman civilisation a century before the conquest under Claudius, and that period of respite sufficed to show the natives whom they had to fear, and the best means of defending their shores and estuaries against a surprise attack. Till recent years the attainments of the ancient Britons have been strangely underestimated, and without exaggerating their capacity we may assume that their standard of civilisation was little below that of their Romanized neighbours across the Channel.

That chariots were extensively used by the Britons in warfare is clear from the narrative of Cæsar, and the large number under the command of Cassivellaunus in B.C. 54 implies an elaborate road system at least in his own dominions, and therefore along the north bank of the lower Thames. One of the principal duties of such a force would be to keep a watchful eye on the river traffic; and that Roman boats about sixty feet long ascended the river at least as far as Westminster two or three centuries after the time of Julius is shown by the recent discovery of such a vessel below ten feet of river mud on the site of the new County Council Hall. To watch the river it was necessary to have a regular roadway on high and dry ground as close as possible to the water, and this was practicable only on the north bank near London. East of the Lea, and a good way beyond London on the south, the banks would be useless for such a purpose; and it is interesting to find the remains of an ancient road running east and west on the brow of the hill just above what is now London Bridge. When that road was first engineered we can only surmise, but it was certainly built or rebuilt by the Romans, for an entire section of it was made and published in 1833 during alterations for the bridge-approach in what is now Cannon Street, but was then called Great Eastcheap. A gravel road 16 ft. wide, supported by two walls 7½ ft. high, was found about 3 ft. below the modern roadway pointing to London Stone on the west and apparently to Aldgate on the east, but it has not been traced east of Gracechurch Street. Narrower by 8 ft. than Watling Street, as discovered in Edgware Road, it lacked the layer of flints that distinguished the Roman military roads; but there is no doubt of its Roman construction, as the containing walls have bands of the familiar tiles between stages of Kentish ragstone. The position, however, suggests an earlier British origin, and if this road were to enable horsemen to patrol the river and give notice of any hostile approach by water, then we must imagine it continued, at least westward, along the brow of the steep northern bank, and crossed the Wallbrook, which was at that time a broad tidal river running into the Thames at Dowgate Hill. That there was a bridge here in Roman times is practically certain, as the sill of a bridge, stout

oak piling and lumps of herring-bone pavement have been found just at this point. The Wallbrook once crossed, the road would naturally proceed along the south side of St. Paul's and down Pilgrim Street to the Fleet, which was, no doubt, crossed by a ferry. Its subsequent course would be quite conjectural were it not for the occurrence of three Roman burials that exactly indicate a line that is more than probable on other grounds. It is common knowledge that the Romans laid out their cemeteries along their main roads, but the evidence of burials with regard to roads has been rather neglected in this country, and it is surprising to find how useful these scattered and accidental discoveries are in the neighbourhood of London. Indeed, the roads for which there is least presumptive evidence are the best attested by burials along their course, and the present instance is, perhaps, the most illuminating. A stone coffin was found in Howard Street, Strand, and cinerary urns under the portico of St. Martin's-in-the-Fields and at the west end of Cockspur Street. If the theory holds good, a line drawn between these sites should indicate the course of a Roman high road, and the only line that satisfies the conditions runs from Bridge Street, opposite the foot of Pilgrim Street, through the Temple, under Somerset House, between this hall and the Strand, past the National Gallery on the north (and higher) side of Trafalgar Square, under George III.'s statue and the Waterloo monument, across the south side of St. James's Square and the west end of King Street, to enter St. James's Park a little above the bandstand, whence still in a straight line it would follow the high ground to the Tyburn valley. Crossing the stream—no doubt by a bridge as the banks are somewhat steep—it would, in a few yards, reach the south end of Park Lane, and Hyde Park Corner has always been an important landmark. Nor need we give up hope of following it still further, for though connected with the Thames it could not well have crossed the low and then swampy ground south of Knightsbridge. The drainage of Pimlico is one of the wonders of London, but of quite recent date; and further west the bends of the river enclose flat areas then, if not now, liable to floods; but a road was practicable on fairly high ground to Brentford, which there is reason to believe was the objective of this ancient highway. The former importance of this town may be partly explained by a ford over the Brent and by the fact that here is a stretch of gravel in the Thames bed which made it possible to ford the river at low tide in the days before steamboats rendered a deeper channel necessary. A few years ago Mr. Montagu Sharpe convincingly argued that here was the spot where Cæsar crossed the Thames, and the existence of a large number of stakes in the north bank is in full agreement with Cæsar's own account of the crossing. For him there was only one ford, and that a difficult one, to take him into the territories of Cassivellaunus, and here, if anywhere, would be a British stronghold reached by well-kept roads. The supposed road from Brentford to Hyde Park Corner is practically in the same line as the section from the latter point to the Fleet, and in my opinion both belong to a system elaborated by the ancient Britons for their own safety and convenience. It may be remarked in passing that the road west of the Fleet, which seems to be marked out by the burials with mathematical precision, exactly coincides with the Terrace of the Inner Temple. The whole group of buildings is evidently based on that line, while the Strand frontage is ignored; and if the Terrace is, in fact, a remnant of this early highway overlooking the Thames, the curious alignment is easily explained.

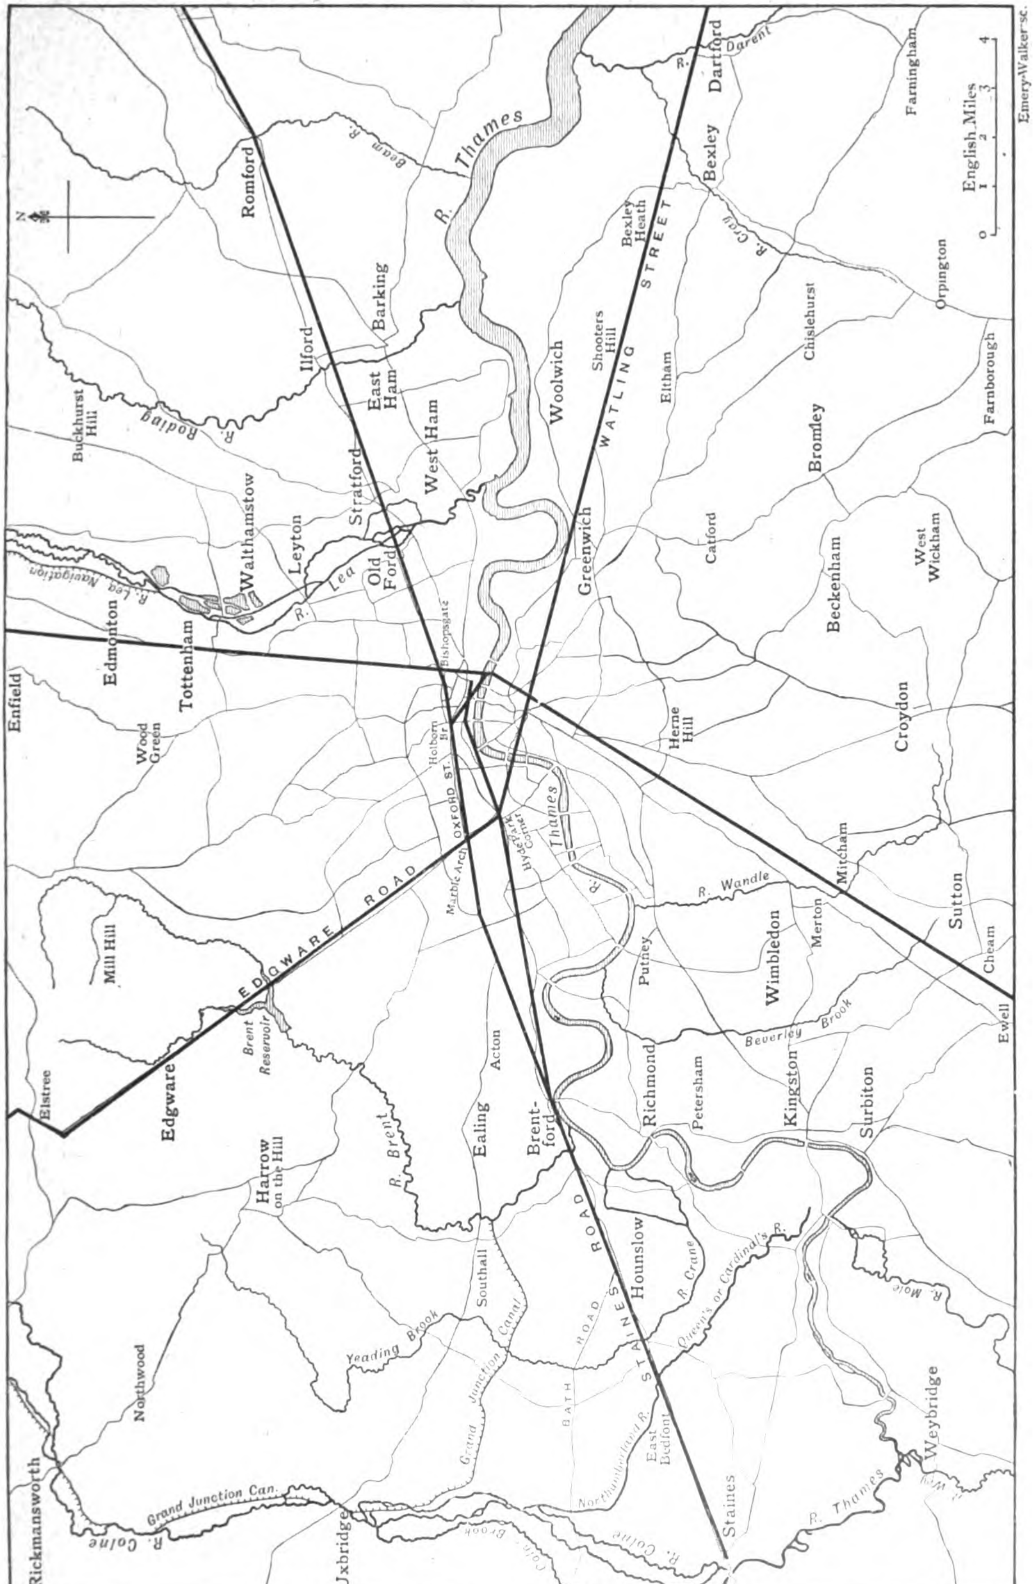
The advantages secured to the Britons by this road would also appeal to the Romans, to whose engineering skill and thoroughness may be attributed the straightness and stability of this secondary highway. Another road of more importance may also have been laid out before the Roman Conquest, but its length and directness point unmistakably to Roman initiative, and at least near London may, without much hesitation, be assigned to the latter half of the first century. Here, as in other cases, a clue to the original course of the road may be gained by producing the straight lines that still exist outside London, but a word of caution is necessary as to the name of Watling Street. In Kent there is no ambiguity, but in the Metropolis the presumed original highway of that name must be clearly distinguished from the street that runs east from St. Paul's to Queen Street. The latter will be discussed in another connection, but at first the Roman highway from the Kentish ports to Chester seems to have avoided the city and crossed the Thames at Westminster. And here may be interpolated an interesting piece of history that seems to be capable of an exact interpretation on these lines. A stage in

the conquest of Britain was marked by the arrival of the Emperor Claudius, for whom a victory had been arranged by Aulus Plautius in A.D. 43. The historian Dio Cassius was born a century later, but probably had access to documents which taught him as much about the British campaign as the ordinary Englishman knows about Trafalgar or Waterloo; hence the outlines of his story at least may be taken as correct. After the Romans had crossed a river that the Britons thought would stop them, the latter, he says, retreated to the River Thames, where it debouches into the ocean and becomes an estuary at high tide; and easily passing it, as they were well acquainted with those parts which were firm and fordable, were pursued by the Romans, who failed to overtake them; but certain Celts—who even under arms were accustomed to swim with ease over the most rapid rivers—again swimming over, and others passing a little higher up by means of a bridge, they attacked the enemy on every side and cut off many; but, rashly pressing on the remainder, they wandered into the pathless marshes and lost many of their own soldiers. This story is circumstantial enough to be credited, and there is no doubt about the river being the Thames; but the site of the engagement has been disputed. The problem is to find a short stretch of the river which at one end was just fordable and bordered on the estuary—that is, suddenly spread from a confined bed into lagoons or marshes covered at every tide—and at the other was narrow and shallow enough to be crossed by a native bridge before the Roman occupation. If estuary implies salt water the problem is insoluble, but if interpreted as above the words are in striking accordance with the report of the Geological Survey. Mr. Whitaker states that London is the first spot where vessels going up the river would find a narrow low-water channel close against ground of the most favourable kind for permanent occupation, ground, indeed, yielding every advantage that our distant forerunners could have wished for; and their choice has been fully ratified by succeeding generations who have built up the great city. Above London there are only narrow strips of alluvium, the river flowing between gravel banks and necessarily keeping to a narrow channel. Below London, however, the scene was far different from what we see to-day. The river flowed through mud plains covered with water at high tide only, and at low tide showing broad spreads of treacherous mud, as at Southend at the present day. Firm land was only touched at some of the bends in its course, as at Greenwich and Woolwich. The Lea valley may be taken as the limit of low ground on the north bank, and the river at the Custom House may well have been fordable at low tide, though dangerous to those not familiar with the crossing. Improbable as it may seem to-day to anyone standing on London Bridge, it is nevertheless supported by facts that came to light during the demolition of old London Bridge. Sir G. B. Airy, late Astronomer Royal, stated half a century ago that the depth of the foundations of the piers was good evidence of the depth of the river at old London Bridge. It appears from a published cross-section that the lowest part of the rubble, on which were laid the wooden sleepers supporting the masonry, was only from two to three feet below low water. It is certain, he says, that this could not be higher than the general bed of the river, and it probably would be lower. Some channels naturally would be deeper than the general bed; and these, when the tide had risen a little, would make the operation of fording very dangerous.

If the dangerous British ford was at or near the Custom House, the bridge was not far off; and in view of the course of Watling Street there can be little doubt that the bridge was at Westminster, which would be about $2\frac{1}{4}$ miles above the ford or, as Dio says, a little higher up. That the construction of a simple bridge here would not baffle the ancient British is suggested by the fact that in 1846 a man forded the river at this point, as recorded in the *Gentleman's Magazine*.

Towards the British bridge, therefore, at Westminster the highway was directed, and a straight line in continuation of the fine stretch of Roman road on Shooter's Hill skirts the river at Deptford, crosses the Thames a little south of the present Westminster Bridge, and reaches the southern end of Park Lane, where it may be presumed to have turned into the line of Edgware Road; for a prolongation of that road would almost coincide with Park Lane, and naturally stop at what we have already supposed to have been an important road-junction. This, at any rate, is the solution suggested by a consideration of outer London, and by the observance of the Roman rule that roads run straight unless turned aside by serious obstacles The Edgware Road

MAP 1.



ENVIRONS OF LONDON WITH MAIN ROMAN ROADS.

is an excellent example, running in a straight line till compelled to swerve in ascending Brockley Hill; and the onus of proof lies on those who would make the Roman roads crooked without weighty and sufficient reason.

Several objections might be raised to this route, and some may be briefly answered. The avoidance of London may only show that the city was not at the time important enough to divert the road, or possibly an avoiding line was chosen for through traffic, just as on a modern railway system. At first London was not a commercial centre, and Westminster also had a gravel subsoil, at least in the line of the road, and the additional advantage of a bridge. The line as restored passes very near a bend in the river at the mouth of Deptford Creek, and though some engineering difficulties would be encountered, this point of contact would furnish a site for a dock. Goods could be conveyed to this point by water more easily and more cheaply than by the road from the ports of Kent, and could here be put on shore for transport inland; and we shall see that London had its own docks later, on the north bank, a little further up the river. Leaving Deptford, the highway struck right across what is thought by some to have been a huge lagoon or morass in the Roman period; but this view of South London is clearly incorrect, as Roman remains and especially burials indicate dry and firm conditions in an area that has a subsoil mainly of gravel. Most of the burials along this line are not definitely located, but those at the Deaf and Dumb Asylum in the Old Kent Road and west of Deverell Street exactly accord with this theory, and flank the road on either side. Passing about 130 yards north of the Elephant and Castle, the line reaches the river near the middle of St. Thomas's Hospital, and the vicinity of Stangate (Stonegate) is significant, as probably preserving the memory of an approach to the river that was paved by the Romans. Stanegate is also the name of a Roman road near Vindolana (Chesterholm), just south of the Roman wall in Northumberland.

In the fourteenth century, when there were probably clearer traces of the Roman highway than there are to-day, there lived a monk named Higden who was connected both with Westminster and Chester, and had therefore probably travelled over great part of the Watling Street. In the Polychronicon he described this road as crossing the Thames to Westminster and beyond, westward to a point at which it turned towards St. Alban's. That is at least what I consider a fair reading of the text which has been variously translated and interpreted. The critical words are *ad occidentem Westmonasterii*, which I take to imply a continuation to the western part of Westminster, and not a passage of the river at a point which lay on the west of Westminster. The map shows this would be an absurdity, as the Thames, for about half a mile above and below Thorney, flows from south to north, and Westminster in those days meant Thorney. On the other hand, Higden's words seem to agree absolutely with the route suggested above.

It was long ago pointed out by Dean Buckland that a bank of gravel stretches from the river westwards almost to Buckingham Palace, and the builders no doubt availed themselves of this firm foundation for their road, which, however, had to cross some low-lying and, at that time, marshy ground before reaching the bottom of Park Lane. The lake in St. James's Park is a relic of these conditions, but had not always its present form. The road would cross about halfway between the bridge and the fountain, and to-day a stretch of lawn between two banks may mark its original course. In the Green Park also may be observed a cutting in the west bank of the Tyburn—rather steep on the north side of the Park—that lies in the direct line to the supposed junction in Piccadilly.

From the map it is fairly obvious that Park Lane represents a southern continuation of the Roman road that practically coincides with Edgware Road, and from the elbow in Piccadilly we may suppose the road ran in a straight line to Brockley Hill. Nor is this a mere supposition or tradition; the actual road was struck in 1902, almost exactly in the middle of Edgware Road, opposite Seymour Street. Another discovery, unhappily not so precise, seems to shed fresh light on the intersection of Roman roads at the Marble Arch. In Rocque's map of 1746 is marked the position of a stone against which condemned soldiers were shot inside the Park, civilian criminals being executed at Tyburn gallows just outside. It was described as a Roman "geometric" stone, that is, a stone set up as a landmark by road-surveyors, and probably inscribed with distances to various points. The intersection near the Marble Arch of two important Roman highways (the original Watling Street and that from Romford to Staines) would fully account for the position of the stone which, on the map, lies in the middle line of the avenue. It was to be seen before 1822, a few yards south of Cumberland Gate, but during alterations of level in that year for a

new gate it was covered up, being too deeply embedded for convenient removal. This in itself is extremely significant, and will be discussed later in connection with London Stone, from which it is about 3½ Roman miles distant.

The east-and-west road is characteristically Roman in its defiance of minor obstacles and adherence to the straight line, but did not actually pass through Roman London. It led from Essex across the Lea to Holborn, along Oxford Street and Bayswater Road over Notting Hill to Brentford, where it joined the British highway already noticed, and thence to Staines and across the Thames to Silchester and beyond. Though its course through Essex and west of Holborn is fairly well established, the intervening portion that skirted the north wall of the city is more conjectural, and it is only in the last few years that indications of the line have been noticed. Even without this fresh evidence, one could guess at its position by producing the line that is fairly clear from Romford to Stratford Town Hall, and this would pass through Old Ford, under Bishopsgate goods station, Finsbury Square and Smithfield to Holborn Viaduct. Beyond this the direction is slightly altered, but another long stretch takes us in a straight line to Notting Hill. That such was indeed the original route is virtually proved by the following considerations. About four years ago lumps of tiles, cemented together to form a herring-bone pavement of a common Roman type, were dredged up by the Lea Conservancy Board in the Lea just below the lock at Old Ford, exactly at the point where our imaginary line would cross the river. That there was once a ford hereabouts is clear from the name of the district, but so far as I am aware its exact position had not been previously determined. It was at Old Ford that the Lea was generally crossed before Bow Bridge was built, about the middle of the twelfth century; and it is recorded by Lysons that Matilda, wife of Henry I., caused two bridges to be built over the Lea and its tributary, the former known as Bow Bridge and stated to be one mile from the old ford. The two points are, in fact, just half that distance apart, and the Roman ford approximately coincided with the line of Iceland Street, a little below the crossing of the outfall sewer. At least two burials at Old Ford station, and another behind the police station at the eastern end of Bethnal Green Road, seem to have been connected with this road, which further west runs straight across Moorfields, a fact that might at first sight cause some misgivings. The Roman wall round London, enclosing an area of about 360 acres, was built across the Wallbrook, then a considerable tidal stream which passed through gratings in the foundations. Either through neglect or of set purpose the citizens allowed these gratings to be clogged with river-weeds and refuse, as proved by excavation in our own time, and the result was that the water was dammed back outside the wall, and in time spread over what was later known as Moorfields. This area was skated over in the time of Henry II. and remained a waste till drained and turned into a pleasure garden early in the seventeenth century. It was suggested by Stukeley that the morass was deliberately formed to protect the city on the north, but in any case we must assume that before the wall was built Moorfields was firm and dry, with a gravel soil capable of bearing a main Roman road, as is shown by a child's burial there containing a gold coin of Salonina, wife of the emperor Gallienus (253–268). Though most authorities are in favour of the fourth century, it is conceivable that the wall was already built in the middle of the third, but the morass cannot have been in existence when the interment took place. Some time after that date the east-and-west road must have been ruined by the swamp, and a way round must have been devised. The nearest high ground north of Moorfields is marked by the line of Old Street, and in this thoroughfare, where it is joined by Goswell Road, two Roman road-levels one above the other, were found in 1867 during some deep excavations which revealed mediæval roads above. This diversion enabled traffic to pass easily between Holborn Bridge and Norton Felgate, without going through the city. At Smithfield interments of both kinds (cremations and inhumations) have been found in considerable numbers, and here, as elsewhere, the angle between two main roads seems to have been a favourite burial-ground. Other burials further west give a clue to the position of the road after the Fleet was crossed by a bridge, probably at the bottom of Snow Hill. In fact, the *Gentleman's Magazine* of 1750 records that in digging the foundation for Holborn Bridge, remains of the Roman military way were discovered pointing directly to Newgate. A straight line from here to the Marble Arch does not coincide with Holborn and Oxford Street, but passes burials on its north near St. Andrew's Church, at the Birkbeck Bank, and another on the south in Endell Street. This line includes part of High Street, Bloomsbury (which was the principal street here till New Oxford Street was opened a

few years ago), and gradually approaches Oxford Street as it proceeds westward.

The two main roads that remain to be considered seem to have met on the Thames bank at a spot always of special importance to London, and probably the site of the first wharf on the north bank of the river. To determine this point we may first produce the lines of recognised Roman roads in the suburbs and then test the accuracy of the method by a survey of the archæological and historical evidence.

From Ware southwards to Edmonton there can be traced on the map a line that is continuous with the recognised Roman road that coincides with the highway from Edmonton through Tottenham and Kingsland to the City, and the presumption is therefore that the Roman north road from the Thames ran straight from the river at least as far as Ware. Its course would have been under the old Custom House, a little to the east of the present building, and about one hundred yards west of the Thames subway at the Tower. Opposite this is the point where the line of Roman road known as Ermine Street, on the Leatherhead Downs, would, if produced, strike the Thames, and this coincidence strengthens the belief that these roads were intended to join at a recognised river-crossing where the Romans doubtless erected a bridge on the site of what seems to have been the lowest ford on the river in British times. It is true that a distance of sixteen miles, between the track on Leatherhead Downs and the river, has to be covered by conjecture, except for a fragment of the road at Ewell; but if the straight line was preserved over such difficult ground as the Downs above Mickleham, it may justly be inferred that no deviation would occur on the lower ground towards London, and that the point aimed at on the river was in a line with the surviving remnant on the Downs. Some such connection must be found between these two portions of the Ermine Street (called Stane Street between Chichester and Dorking, and deflected by Box Hill), and the course suggested is not only the most obvious but is supported by a certain amount of archæological evidence. That the Roman road did not coincide with Borough High Street is proved by the discovery of a Roman tessellated floor right in the centre of the latter; and excavations in the City have made it fairly certain that the road did not swerve on entering the city walls and follow the line of Gracechurch Street to London Bridge, for thick Roman walls have been found crossing this thoroughfare. The old London Bridge was a little to the east of the present structure, and has never been proved of Roman origin. The large number of coins, from the Republic to Honorius, and other Roman relics found in the river when the foundations of the present bridge were laid, cannot be taken as decisive, for in the vicinity of a large city the river-bed is certain to contain relics at any given point, and probably as many coins and other objects will be found when the new St. Paul's Bridge is built. Further, there is no guarantee that the antiquities were dropped exactly where they were found. For instance, two halves of a Viking sword have been found in different parts of the river above London, where the scour of the tide is not so considerable.

That the Romans built a bridge to carry their high road across the river at or near the point towards which earlier British roads must have converged, is more than probable when we remember that the army under Julius Cæsar collected the timber and built a bridge over the Rhine at a point where the stream is considerably wider than the Thames at London Bridge, marched over and back again, and then dismantled the bridge, all in the space of ten days. If the Romans bridged our own Tyne, as we know they did, they would in the course of four centuries have found a bridge at London not only desirable but necessary for the traffic of the chief commercial city in Britain; and as we know that a London Bridge existed in the reign of Edgar (tenth century) we can hardly attribute it to anyone but the Romans, unless, indeed, to King Alfred.

In support of this theory mention may next be made of Stoney Lane, which runs parallel to, and a few yards east of, the Ermine Street on the south bank. This is an ancient name, and may have arisen from a paved approach to the river at this point, corresponding to Stanegate at Lambeth. There is also a Stoney Street opposite Dowgate, which has led some writers to put the crossing here, in spite of the fact that the Wallbrook was then a broad tidal river. About seven furlongs south of the river the road would cross the Watling Street, and in the angle thus formed a large Roman cemetery has been discovered in the burial-ground of a chapel (now Salvation Army barracks) in Deverell Street, New Kent Road; and burials in a similar situation have already been noticed at Smithfield. This coincidence is all the more striking, as the inhabitants of Roman Southwark seem to have buried their dead generally on the outskirts of their

diminutive settlement half a mile north of the cross roads in question.

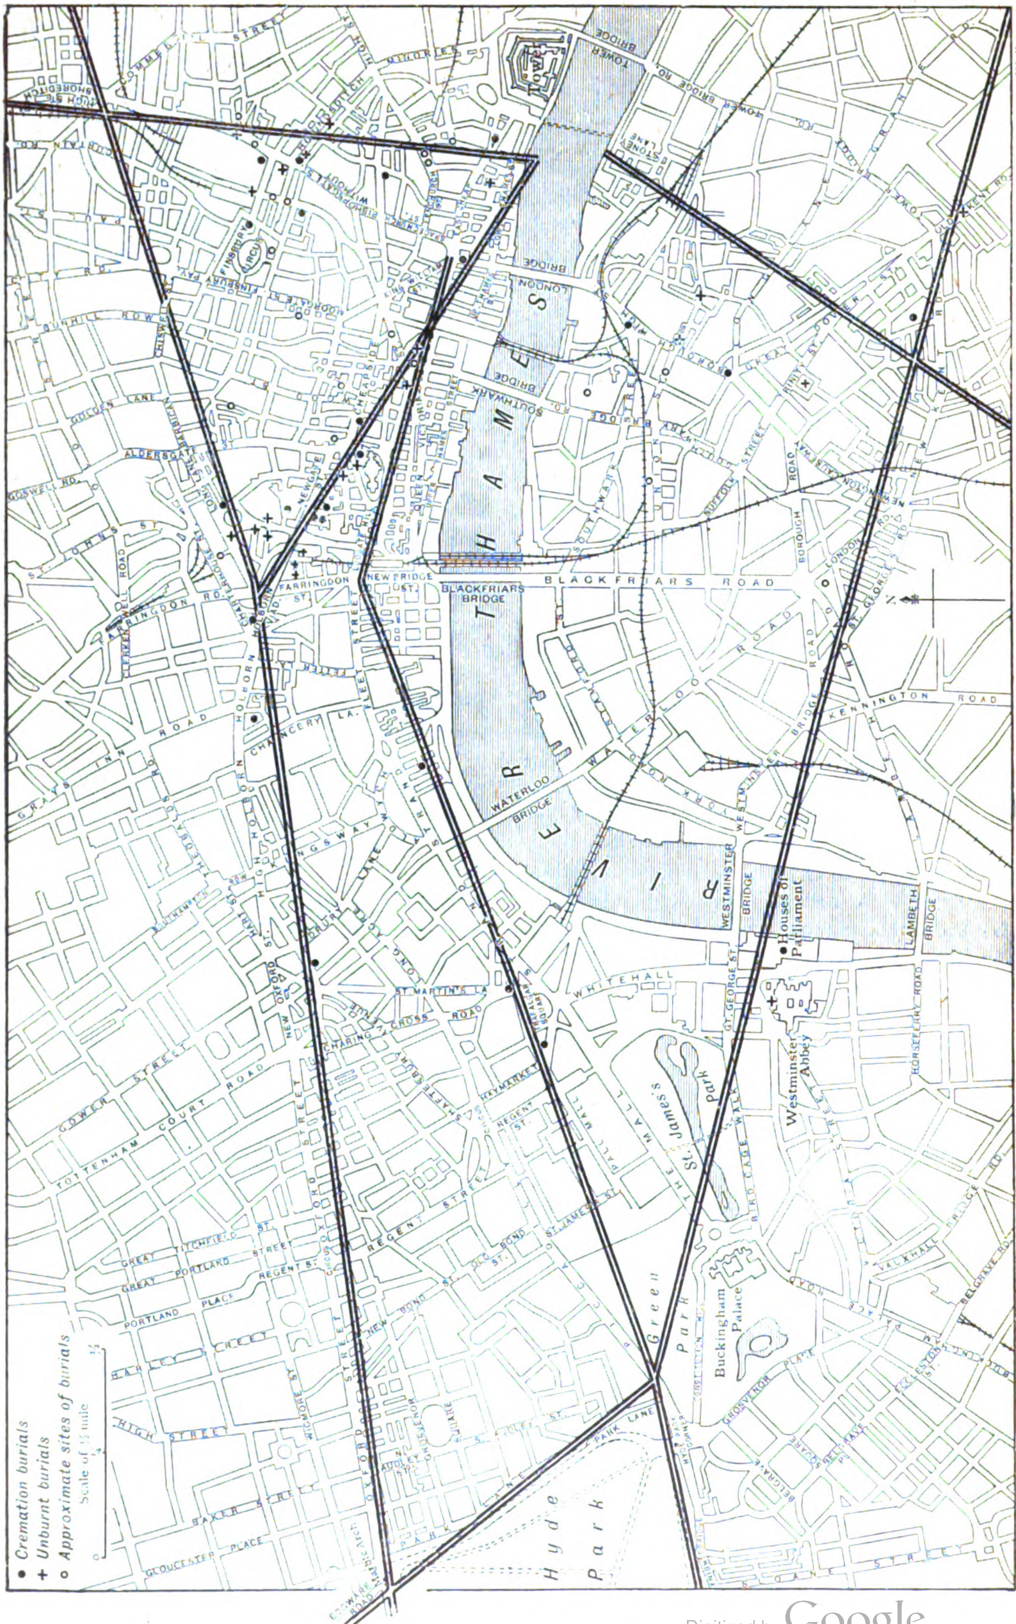
North of the river the problematic course of Ermine Street is fairly marked out by the burials in Artillery Lane and Bishopsgate Street Without, Goring Street (formerly Castle Street in Bevis Marks), Fenchurch Street, Mark Lane, and All Hallows, Barking; and Billiter Street with Mark Lane may represent the ancient line. But this line is probably not so ancient as the others. It is a curious fact that this route to the north is not mentioned in the "Antonine Itineraries," a military road-book of Britain of somewhat uncertain date, but, in its original form, attributed by the latest writer on the subject to the first decade of the third century, the name being presumably derived from the Antonine Emperor Caracalla (A.D. 198–207). Travellers wishing to reach the north were in that work directed to use the Romford or the St. Alban's road for the first part of what was a roundabout journey, and we can safely conclude that the road through Ware was not then in existence. In any case the direct route passed through marshy country on its way to Lincoln, and seems to be the last link in the road system round London. On the other hand, a road, which to all appearance started from the same point on the north bank of the river, seems to have been constructed at a comparatively early date in the Roman period, though no trace of it is to be found in the "Itineraries," no doubt because it was at first merely a branch road. Evidence has already been brought forward to show that the wall round London dates from the end of the third or some time in the fourth century, and the occurrence of burials flanking this road indicates that it was laid out before the building of the Wall. East of the Wallbrook, burials are rare within the Wall, but beyond that stream they are plentiful along the line in question; and it is difficult to believe that the Roman authorities would have tolerated burials in that area after the Wall was built. Though some of the burials date from the first or second century, there are others with the unburnt body that seem to belong to the period after the change from cremation to inhumation, which, in my opinion, took place about A.D. 250. The houses near St. Paul's, in one of which fourth-century coins were found, would, on this hypothesis, not have been built till the burial-ground was disused and perhaps forgotten, presumably after London became a walled city.

A glance at the map will show that a road was wanted to communicate with the great north-west highway known as Watling Street for conveyance of goods, not to mention troops, from the principal landing-place in London. This end would be served by the road suggested on the plan between the Custom House, where it would join the Ermine Street, and Newgate, where it would unite with the east-and-west road and cross the Fleet by one and the same bridge. In this way the detour by Westminster would be avoided; and even if the Ermine Street was in existence when this road was planned, a good mile would be saved by traversing one side of the triangle instead of joining the east-and-west road at Norton Folgate and traversing the other two sides.

This road is marked out as well as any by the burials, and though not a continuation of any known Roman highway, has actually been found about the middle of its course. This line would link up interments in King William Street, Cannon Street, Cheapside, St. Paul's Churchyard, Paternoster and Warwick Squares, Old Bailey and Newcastle Street, and though the first two sites might be explained as abutting on a still earlier British road, the rest are obviously connected with the Customs House-Newgate road, which has other points of no less interest. Its sloping course leads gradually up the steep river-bank and joins the presumably British road in front of Cannon Street Station. It is just at this point that London Stone originally stood, in the middle of the road about 35 ft. south-west of the recess in St. Swithin's Church wall, where a fragment is preserved; and it may well be that the stone stood at the intersection of two roads as the firmly-set "geometric" stone seems to have done at the Marble Arch. The history of London Stone has been traced back for many hundred years, possibly to the tenth century; and it has always been regarded as of monumental interest. Its mediæval history need not detain us; but it is important to notice that when its massive foundations were unearthed by Wren after the Fire, they seemed to him to have formed part of some public building; and tradition has it that this was the mile-stone from which all distances were measured in Britain.

The two roads that met in Cannon Street would probably cross the Wallbrook by a single bridge and part company again on the western side; that on the north passing along Budge Row and crossing Queen Victoria Street between two churches, St. Mary Aldermanbury, and St. Antholin (now demolished). Excavations in 1869 revealed a road at a depth of 10 ft. 3 in. at this spot, nearly in a line with the present Watling Street. "It was hard and well made,

MAP 2.



COURSE OF ROMAN MAIN ROADS THROUGH LONDON.

slightly elevated in the centre and formed of rough stones and gravel, in the upper portion of which were found quantities of broken Roman pottery which, with other local circumstances, would lead us to the conclusion that it marked the course of a road or highway of some antiquity." For a short distance west of this point our line runs along Watling Street, where it has been found, and the name is more or less appropriate, as this road probably superseded to a large extent the Westminster portion of the Watling Street from Kent, when London had risen into importance. Its connection with St. Paul's Churchyard is indicated by another discovery by Wren. "Upon demolishing the ruins after the last fire and searching the foundations of this Quire, the surveyor discovered nine wells in a row; which, no doubt, had anciently belonged to a street of houses that lay aslope from the High Street (then Watling Street) to the Roman Causeway (now Cheapside); and this street which was taken away to make room for the new Quire came so near the old Presbyterium that the Church could not extend further that way at first." A similar row of wells abutted on the Roman road in Cannon Street.

There is another record of flint pavement about 13 ft. from the surface, below two layers of burials on the north side of the east end of St. Paul's, and below the pavement fragments of "Samian" ware, evidently of the second century. The remarks on Roman burials near St. Paul's apply still more forcibly to the few found within the walls on the east side of Wallbrook, as in Crooked Lane, on the site of East India House and at St. Helen's, Bishopsgate. On the last site a marble cist was associated with a coin of Constantine II., which might indicate a subsequent date for the building of the Wall; but the point is that no burials seem to have been found in a well-defined rectangular area roughly bounded by the Wallbrook on the west and by Cannon Street on the south. Gresham House would be about the middle of the north side, and the east would be in a line with East India Avenue. It may be accidental that London Stone is at one angle of this enclosure, which has an area of about fifty or sixty acres, closely corresponding to that of a legionary camp. The prætorium or headquarters of such a camp would approximately coincide with the site of St. Peter's, Cornhill, under which massive Roman walls have been found extending westward to St. Michael's Church and eastward under Leadenhall Market. In the opinion of Roach Smith and other well-known antiquaries these were connected with an important public building, and an apsed building resembling a basilica was found under the market. Close by, at the cross-roads, probably the Carfax of London mentioned in two ordinances of Edward III., stood the Cornhill standard, a fountain of such importance as a landmark that distances on milestones throughout England, we are told, were measured from it as from the heart of the city. There is, therefore, some ground for considering this point the centre of Roman London. The city developed, I suggest, from a legionary camp, no doubt occupied in force at the very outset of the Roman conquest and possibly later by legions on the way to the front, but soon given over to a civil population, which rapidly made it the leading commercial city of the province. It is interesting to note in this connection that St. Peter's claims to be the first Christian church in Britain, and certainly ranked higher than a parochial church in the Middle Ages, for its school was one of four maintained by order of Parliament in London. Its foundation by Lucius in the second century is, no doubt, fanciful, but there may be some justification for the claim that it was the seat of a bishop or even archbishop in the Constantine period.

There is certainly one, and perhaps more than one, main road in or near London that awaits discovery, but perhaps those already traced will have given pause to the critical historian or archæologist. To those accustomed to the haphazard road system of modern London, the straight-edge may seem a crude and inadequate instrument for restoring the main routes of the Roman period; but our conquerors had practically a clear field and were addicted to straight roads, even in districts where they found greater natural obstacles than near London; and there are coincidences that seem to confirm the system above described. Other critics may consider that too much stress has been laid on the discovery of burials more or less in line, and may point to several burials in the London area not so arranged and presumably independent of any main road. To these I would reply that interments have been occasionally found in Britain in close proximity to Roman villas, away from main roads, and the erection of tombstones along a main thoroughfare may have appealed more to the well-to-do than to the humbler members of the community, who would be content with an unostentatious burial close at hand.

It is, from the archæological point of view, regrettable that no Roman cemetery has been thoroughly excavated and recorded in Britain, and that we have to look abroad for much of

our evidence of date. Years of patient work at Silchester, for instance, have placed before us a Roman provincial town with realistic effect, but the most useful piece of work there is still undone; the burials of its Roman and perhaps British inhabitants are still unexplored and even undiscovered, and the only consolation is that they are still intact. The records of such discoveries in London are provokingly inadequate, but they have at least been collected and examined, I hope to some useful purpose; and the results obtained may, perhaps, direct attention to this period of our city's history, and rescue from destruction any similar relics of the past that may hereafter come to light.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said it was a great thing for Londoners that they possessed an official at the British Museum who devoted himself to work of the kind dealt with in the paper, in a way which showed that he built up his extraordinarily brilliant and elaborate theory from a long series of observations which involved a tremendous amount of research. He was one of those who held that Roman London was really the basis of modern London, and any research that brought forward information which proved what that Roman London was seemed to him to be of the greatest value. To Mr. Montagu Sharpe's elaborate research into Middlesex as the *territorium* of London might now be added the author's important paper on the roads of London. He wished to enter a very small protest against one fallacy which he thought the author would do well to get rid of, namely, that he seemed to base a good deal on the theory of an ancient British civilisation. There was absolutely no necessity to imagine a pre-existing British road in order to build up the Roman road theory which the author had placed before them, and he did not quite see why Mr. Smith should have drawn their attention to a British civilisation because the early Britons possessed coins and very considerable works of art. Anthropologists knew that the Maoris of New Zealand had very elaborate and wonderful works of art, but that did not prove they were a civilised race. It seemed to him that the author could very well throw that part of his research overboard and begin straight with his Roman work. He reminded him that the Celtic Britons were in the condition of tribesmen, as was proved by the fact that their post-Roman laws were tribal laws, and that it was impossible to convert tribesmen into people who built roads, not only through their own tribal territory, but through the territory of their adjoining enemies. The thorny question of the ancient Briton seemed to dominate the author's mind, because he (the Chairman) noticed one particular sentence in the paper in which the statement was made that Westminster and not London should have been the capital if its British importance was taken into account. There, again, he did not think history supported Mr. Smith. The extreme importance of Westminster in relation to London was not its British, but its Anglo-Saxon position; and he threw that out as a point which did not bear out this particular part of the author's theory. The author's theory was that the Romans buried, at all events their principal people, on either side of the roads which came out from the big city. When it was borne in mind how London had been dug into, and altered and changed, the remarkable thing was, not that so few burials, but that so many burials had been discovered. To have gone over the map of London and to have selected those burial places as the possible sites of Roman roads seemed to him a very remarkable and extraordinary piece of work. When the route of those roads was confirmed by other evidence he thought the author's theory might be taken as proven, although he confessed that when he saw the ruler going through all sorts of other roads across the modern map he was rather alarmed; but were they quite safe in neglecting the evidence of a modern road where it might give some sort of evidence of the ancient position? One other point that struck him as of extreme importance was the identification of the ancient Roman camp which was destroyed by Boadicea. That site was a very important one, and he thought the author's identification of it was a noteworthy example of his method of research. It was true it was based upon negative evidence that burials were not found within a particular area, but the evidence was very strong, and when coupled with the remarkable identification of the buildings on the site of the *praetorium*, seemed to him to be worthy of the very greatest consideration.

Mr. MONTAGU SHARPE said he had always taken it for granted that the roads which the author had described in the paper were more or less in their present position, but he had been considerably impressed with the author's statements in regard to burials taking place alongside the main roads. In the parish of Enfield he had visited a Roman cemetery which was at least a mile and a half from Ermine Street, and he knew of another Roman cemetery in the County of Middlesex which was a long way from Watling Street. He therefore desired to ask the author whether he confined his theory with regard to Roman burials only to the consular and military roads, or did he contend that burials might take place along the ordinary minor roads of the countryside? The prefecture of London embraced a large area, which must have contained a considerable population, so that there might be Roman remains all over Middlesex. Did the author hold that the Romans buried their dead by the side of the local roads, or was the burial

indiscriminate in their own grounds? If the author's theory held as regards rural burials, it would be of great assistance in tracing a great many of the minor roads in the county of Middlesex.

Mr. H. B. WHEATLEY said he was pleased to have the opportunity of expressing the great obligation every student of London was under to the author, first of all for his contribution to the "Victoria History of London," and also for the present paper, which contained one of the most remarkable contributions to the knowledge of the subject which had hitherto been written. He had been particularly pleased to hear the author's description of St. Giles's, because one of the greatest difficulties he had experienced in considering Oxford-street and Holborn as a Roman road was the way in which it went down through St. Giles's. Mr. Smith had fully explained the reason why it did so, and had, therefore, entirely overcome that difficulty. In looking at the maps which had been shown containing the Roman roads, he had been greatly struck with their number, and it was hardly possible to understand why at that early period of Roman history so many roads should be required. The idea that a bridge was built at Westminster in place of one in London seemed rather extraordinary. It appeared to him impossible that a bridge could have existed at one time and have been so completely lost. It was a point which was arguable, but it was a great shock to one's feelings, similar to that obtained from Sir Walter Besant's book where he specially contended that Westminster was earlier than London, of which there was no evidence at all. The author had rightly pointed out that the reason there was no growth at that place was because of the swampy nature of the ground. By the fourth and fifth century it was natural to suppose that many things had grown; and, as there was a part of Roman London in Southwark, it did seem as if the ordinary idea of going across from Southwark to London was correct. As to the question of a bridge, an important point in the author's argument was that it was built by Britons. It was natural to suppose the Britons would have experienced difficulties in bridge-making which the Romans did not experience. From the Roman point of view it seemed to be not a question of building the bridge at the shallowest part of the river, but at the narrowest, and the district at Westminster would be rather wider than, or as wide as, that at London Bridge, excepting that part which was swampy on the other side. That seemed to be the great difficulty in connection with the possibility of a bridge being built at that time; it depended very much on the use of the road.

Mr. WILLIAM PAGE thought the author's remarks with regard to the course of Watling Street, crossing the Thames from the south side to Westminster and going through to St. Albans, threw a light on the question of the early status of London. It would be remembered that the goal of Caesar's invasion was Verulamium, and when Claudius invaded this country, the only place which the Romans made into a *municipium* was Verulamium. Hence he thought that Verulamium was the most important town in southern Britain, and probably the most important in all Britain. The first time that London became of importance was on the insurrection of Boadicea in A.D. 60, and it was then coupled with Verulamium and Colchester. The position of London was afterwards recognized by the Romans as being far more important, and towards the end of the first century it became a much more important town than Verulamium. With regard to the geometric stone at the Marble Arch, to which the author had referred, that part of Middlesex was in the Hundred of Ossulston. In a minister's account of the Manor of Ebury at the Record Office, there was a description of various farms in Ebury which extended up to Oxford-street, and in the northern part of the Manor of Ebury there was a reference to a farm very close to Osolveston, which was the old form of Ossulston. Such a geometric stone would be the sort of place which would be chosen for the meeting of the Hundred Court. With regard to the road that ran from Chichester to London, the author mentioned that that road must have been made after the date of the Antonine itinerary, about A.D. 320; and if that was the date of that road, was it not also the probable date of the Roman London Bridge?

Mr. MILL STEPHENSON could not understand the importance which the author attached to Westminster. Débris of a Roman city had been found in the City, whereas practically nothing had been found at Westminster except the doubtful burial to which the author had referred, where a Roman coffin had been found with a Christian lid. It was very unfortunate that it was impossible at the present moment, owing to the attitude taken up by the owner of the land, to explore further the Roman cemetery at Silchester.

Mr. T. F. ORDISH thought the drawing of lines on a map in accordance with the Roman cinerary urns discovered along them, and indicating in that way the course of the Roman roads, was a fruitful field of research which many people would like to adopt, but unfortunately they did not possess the information which was at the author's disposal. He thought all interested in the subject had cause to be grateful to the author for the immense amount of work he had done in that direction. When London was rebuilt, it was rebuilt on the old ways, the alignment of the roads being made very much the same. Many investigators had discovered that the landmarks of property and manors showed that the line of the roadway was permanent. He mentioned that point because there was an important difference between the lines drawn by the author in the case of many of the Roman roads and those that existed at the present time, which, in a general way, had been supposed to be based upon the Roman system.

Mr. Reginald Smith, in reply, said the Chairman had maintained that he exaggerated the standard of civilisation among the ancient Britons, but every year evidence was forthcoming on that point. When it was borne in mind that it was only within the last thirty or forty years that any attention had been given to ancient Britain and the early Iron Age it was astonishing that in that short period so much information had been obtained, and he was daily expecting further discoveries on the subject. Until more was known about the ancient Britons, he thought they ought to be given the benefit of the doubt. The Anglo-Saxon importance of Westminster was no doubt true, but there was certainly a Roman settlement there. The settlement at Thorney could only have been small, but within the last few months Mr. Lethaby, who was in charge of the fabric of the Abbey, had informed him that further discoveries had been made in the Abbey itself. For instance, there were two or three finds, which he could not quite locate, in the Close, and quite recently fragments of a pavement three inches thick, as well as several roofing tiles, had been discovered under the apse of Edward the Confessor's Church. He was not surprised to hear there were burials outside London, and even cemeteries which did not flank Roman roads, but he preferred to judge each case on its own merits. If Mr. Montagu Sharpe could show, in his wanderings around Middlesex, lines of burials as well as cemeteries, and connect them either with his (the author's) system of roads, or work out a system of his own, he would be happy to see such work done, but there were cemeteries not connected with roads. For instance, just south of Old Ford, outside the area of the City, on the bank of the River Lea, there was a bunch of six or eight burials, which, as far as he knew, were not connected with the road. He supposed the land flanking the Roman road was monopolised by the well-to-do, just as the best situations in cemeteries were at the present time, and the other people had to be buried wherever a place could be found for them. Mr. Wheatley had asked why there were so many roads. He could assure Mr. Wheatley that there were many more not yet discovered, and he hoped to be able to find the track of the road which was a short cut from Deptford Creek to London Bridge. Most people thought that the Old Kent Road was such a branch road, but he was persuaded that the short cut, if it ever existed, was not exactly on that line, and was certainly later than some of the other roads he had mentioned. He believed the riparian road was not only a main road but an important strategical road. Troops going to the front would have to pass through London and be despatched in all directions. Hence London was the key of the road system, just as it was the key of the railway system at the present day. He hoped some important main roads would be discovered, or at least some burials, between Deptford and London Bridge which would give a key to the situation of the cross-road which he felt must have existed. He could not believe that the road was ever swamped by the Thames in Roman times; it was at all states of the tide above the water level, being practically on the level of the Strand, and it was chosen by the Britons for that reason. When the Romans improved the road, and built up the retaining walls to keep the gravel firm, there was not so much need for the road as before. The Romans policed the country so well that they found they did not need specially to watch the River Thames, and their troops were more useful elsewhere. At any rate, that road might have been superseded by the east-and-west road that came from Romford and went through the north of London past the Marble Arch, over Notting Nill. He believed that was the true Roman road more or less superseding the lower road, which might have been dangerous and boggy in some parts. Mr. Page had reminded him that Verulamium was the centre of south Britain at that time. All the more reason, therefore, that the road which came up from Kent should go direct to Verulamium. London was not so important as Verulamium, in fact, it hardly existed in the first century; therefore the road went on a straight course without regard to London at all. Even after London became an important commercial centre it was quite possible that the Romans went through Westminster, just as a modern railway made what was called an avoiding line outside a busy centre so that through trains could go past the town instead of through it. Mr. Page's discovery persuaded him more than ever that the geometric stone at the Marble Arch was the stone of Ossulston, and great credit was due to Mr. Page for that interesting discovery. With regard to London Bridge, he was quite certain that the Romans did join up Ermine Street over the river by a bridge. When it was borne in mind that the Romans built a bridge over the Rhine, which was twice the width of the Thames at London Bridge, and destroyed it again all within ten days, one could not help thinking they would build a bridge of stone or wood to join up two of the most important roads in the kingdom. If they did not do it, who did? London Bridge was heard of in the reign of Edgar. He did not think the early Saxons would have been the people to build a bridge across an important river like the Thames, and he thought if King Alfred had built the bridge he would have said so. Mr. Stephenson could not have heard of the recent discoveries at Westminster, otherwise he would have known that many Roman remains had been found there. He also hoped public opinion would have some effect on the obdurate owner of the soil at Silchester, who at present prevented the cemetery there being thoroughly excavated.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Reginald Smith for his interesting paper, and the meeting terminated.

INTERNATIONAL COURSES OF LECTURES ON COMMERCE.

A few years ago the International Association for the Promotion of Commercial Education was founded for the purpose of organising Commercial Courses of Lectures each year in different countries. The offices of the Association are at Berne, and the President is Monsieur A. Junod, Département fédéral du Commerce, Berne.

The Association receives the patronage and the financial support of the Governments of Austria, Baden, Belgium, Brunswick, France, Prussia, Saxony, Switzerland, and Wurtemburg.

The prospectus states that the aim of these courses is:—

1. To demonstrate to the students the economic development of the country in which the course is held, while at the same time studying its manners and customs, and its relations with other countries.

2. To familiarise students with the language of the country.

3. By means of excursions to make known the country and its commercial and industrial enterprises.

4. To create intercourse between persons who, in various countries, deal with commercial questions.

5. To examine thoroughly questions relating to the teaching of the Economic and Commercial Sciences, and those bearing on the study of Modern Languages.

Holiday courses of Lectures for the advancement of commercial studies have been held at Lausanne (1907), Mannheim (1908), Havre (1909), and Vienna (1910). All these were successful and well attended.

It is now proposed to give a similar course in London in July, 1911. The object of the Lectures is to familiarise the students (mainly commercial men and teachers of economics from Continental schools and universities) with the history and practical working of English Commerce and Industry.

The Lectures will be delivered at the School of Economics, Clare Market, W.C., from July 24th to August 12th, 1911. The proposal has received the approval of the Council of the Royal Society of Arts.

Arrangements are now being made for securing the assistance as lecturers of the most eminent British authorities on economic and commercial subjects, and satisfactory promises of help have already been received.

An influential committee is in course of formation, and their names will shortly be announced.

The expenses of the courses are partly defrayed from the funds of the Association and partly by the fees of the students who attend; but it will be necessary to supplement these resources by a local subscription, and an appeal will therefore be made to those interested in the movement to provide a sum of about £400. It is estimated, from the experience of previous meetings, that this amount should suffice to carry out the proposed course in a satisfactory manner.

As soon as possible the list of lecturers and a programme of the course will be published.

In the meantime those interested in the subject are invited to communicate with the Organising Secretary for Great Britain, E. Cleveland-Stevens, School of Economics, Clare Market, London, W.C.

RESCUE WORK IN MINES.

The General Report on Mines and Quarries for 1909 by the Chief Inspector of Mines (Cd. 5,399) contains some interesting particulars of the steps which have been taken recently to encourage the training of men in mine rescue work. These steps are largely due to a desire expressed by the Royal Commission on Mines in their second report, issued in September 1909, "that in each district there should be appointed committees of colliery-owners to provide for the erection of stations and training of men, and that a handbook might be drawn up containing instructions in rescue work, with recommendations as to preparations necessary in case of emergency."

The coal-owners, in reply to this, have evinced an increased desire to meet the needs of the colliery districts in the establishment and organisation of stations for training rescue brigades in the use of breathing appliances and in general mine rescue work. The improvement, however, is much more marked in some districts than in others. Special commendation is given to the system in operation at Howe Bridge rescue station in Lancashire, which is supported by a large majority of Lancashire and Cheshire coal-owners. Yorkshire "has been to the fore in this good work in the past, though no fresh developments have taken place in the county during the year." At Cowdenbeath a station has been established for Fife and Clackmannan, and this will shortly be in full working order; but in the west of Scotland practically no progress has been made during the year.

In the north of England the coal-owners of Northumberland and Durham have secured a site at Elswick, where a rescue station is being erected. Here will be stored all the necessary appliances for the work, including a motor for the rapid transit of the brigade, and a motor fire-engine. It is expected that it will be possible to reach any colliery in the two counties within an hour of receiving a call. The organisation of the Elswick station differs somewhat from that in other districts, "in that there will be an organised band at the central station constantly available, but it will not be confined to miners, advantage having been taken of an offer from Sir W. G. Armstrong, Whitworth & Co., Ltd., to co-operate with the band of sixty-eight men under Mr. Simonds, some of whom will act as instructors in the use of breathing appliances to men sent in from the various collieries."

Rescue stations have also been established at Mansfield for the Midlands, at Aberaman for the South Wales and Cardiff district, and at Crumlin for the Monmouthshire Western Valley collieries, but none have been erected in the coalfields of West Scotland, North Wales, Staffordshire and Warwickshire.

Several types of breathing apparatus are in use at the various stations, and opinions differ as to which is the most efficient. In this connection the report draws attention to the action of the Council of the Royal Society of Arts, who have offered the Fothergill Prize of a gold medal or £20 with a view to encourage research in this direction. A considerable number of entries have been received, and an expert committee, under the chairmanship of Sir Henry Cunynghame, K.C.B., has been for some time engaged in subjecting the various appliances to practical tests.

PAUPERISM.

In his Presidential Address, entitled, "A Statistical Survey of the Problem of Pauperism," delivered at the opening meeting of the Royal Statistical Society, Lord George Hamilton said that to take a year antecedent to 1871, the date of our Education Act and other remedial measures, for comparison with the existing state of things, was to apply a misleading test. There should be, in recent years, not only a reduction of pauperism in the ratio per thousand, but also in the actual number of paupers.

From the Pauper Census of March 31st, 1906, it was found that there were (exclusive of insane) 827,939 paupers, and, while in the whole population there was an excess of women over men of about a million, the excess of women paupers over male exceeded that proportion in every age group. The total number of persons having recourse to the poor law during the year ending September 30th, 1907, was 1,709,436, or 2·5 times greater than the mean of the number relieved on January 1st and July 1st of the same year, those receiving outdoor relief outnumbering those in receipt of indoor relief by more than two to one.

The Poor Law Commission found that the cycles of pauperism coincide in their duration and movement with the cycles of expansion and contraction of trade.

From 1871-96 there was not only a reduction in the ratio of pauperism, but also in the number of persons relieved. Since 1895-96 there had been a large increase in the number of persons relieved, and, though the ratio per thousand had not risen, this was due to the increase of population. It was disquieting to find, however, that the great reduction in the number of children relieved just about counterbalanced the great increase in the number of adult men receiving relief. Since 1891, men had resorted to poor law institutions at earlier ages than formerly. There had been a progressive increase in the number of men over twenty in receipt of relief, but the rate of male indoor pauperism to male population of the same ages was higher in 1901 than in 1891 at every age from forty-five onwards. The rate of pauperism was very high among dock labourers, and, generally speaking, highest in those occupations in which the casual system of employment predominates, while they were lowest among carpenters and plumbers.

Poor law expenditure had, during the period 1871-1906, risen from £8,000,000 to nearly £14,000,000, and, notwithstanding the vast increase in population, the rate per head was now 1*s.* 7*d.* in excess of what it was in 1871. Increased expenditure had occurred under the following heads:—In-maintenance; maintenance of lunatics; workhouse and other loans; salaries and rations of officers (largely due to remarkable improvement both in training and number of nurses in poor law infirmaries). Out-relief had diminished. The increase of expenditure had not resulted in a diminution of pauperism, but, on the contrary, while the increase per head during the last complete cycle, as compared with the previous cycle, was nearly £3 per head, the number of paupers in the incomplete cycle, 1905-6 to 1909-10, was 87,000 more than it was in the cycle of 1888-89 to 1895-96.

In the counties pauperism was highest in the east and centre of England, and lowest in the north. In London the number of paupers had increased by 36,000, the ratio had risen from 20·5 to 25·1, and the number of adult men maintained in institutions was greater than in any other part of the country. The general workhouse, while it had placed many heavy burdens upon the rates, had, from the deterrent side, been a failure. As regards children, while it was satisfactory to know that there had been a reduction in the total number of children receiving relief, it had to be borne in mind that the reduction had chiefly been in the number of widows' children, while the number of children of able-bodied parents receiving relief had increased. Least progress appeared to have been made in regard to able-bodied paupers. Vast improvement had been made in institutions for the sick during the last twenty-five years.

Taking the figures as a whole, they were most unsatisfactory, not only as regards the number of paupers in receipt of relief, but also in the development of pauperism in recent years which they indicate. The growth of expenditure was shown to be enormous, although coincident with this increased outlay upon poor law there had been a heavy and continuous increase of expenditure, both in education and sanitary reform. We were certainly now spending upon these three objects, in England alone, forty millions a year more than we did at the commencement of the period, 1871-1906, and yet, at the conclusion of that time, we had more paupers than we had at the time before we embarked upon this increased expenditure. We, the richest nation in Europe, have the heaviest pauperism, yet the more we spend the worse the position seems to be.

ARTS AND CRAFTS.

Metalwork.—It is always a relief at this time of year to visit St. Dunstan's Studio, Seymour-place, South Kensington, and see the little exhibition of work by Mr. Omar Ramsden (who recently received the Society's silver medal for his paper, "Silversmiths' and Goldsmiths' Work") and Mr. Alwyn Carr. Their work is really artist craftwork and not the very inferior article that, especially towards the end of December, too often masquerades as such. The real interest of the collection centres in the numerous important pieces of work executed as commissions by the artists during the past year, and either not yet delivered to the purchasers or kindly lent by them.

Amongst the objects carried out in iron, bronze, and brass, the wrought-iron candlestick for Holy Trinity, Sloane-street, the facsimile of a Grille for the Sacrament House of the Church of St. Philip and St. James, Oxford (in pierced brass with a very satisfactory rendering of the Pelican in her piety), and above all, the Treasury Grille and book-rest in bronze for Cape Town Cathedral, merited special attention. The Grille in particular is a very vigorous bit of bronze-work, and the shields of arms which bear so considerable a part in its design (it is evidently a memorial to the troops who fell in the South African War) are most happily planned.

The most prominent feature of the exhibition, however, was the Processional Cross in wrought silver, fire gilt, for St. Peter's, Eaton Square. The arms of the cross are of mother-of-pearl, and the pierced silver renderings of the Evangelists at their extremities and the Agnus Dei in the centre, together with the wreath of ornament, representing the vine on one side and the wheat on the other, which connects the four members of the cross, forms not only a very harmonious bit of design, but a really beautiful and rather subtle colour scheme. The vine and wheat ornament has a very close affinity to the design of the monstrance for the Westminster Cathedral carried out by the same artists some years ago, but it is, as a design, none the worse for that. Another interesting bit of work was the seal for the Bishop of St. Andrews. The bishop is represented in full canonicals, in the act of benediction, and the long, regular folds of the drapery and the dignified pose help to make the seal the thoroughly satisfactory whole that it is. The lettering of the border, too, is just the right weight to balance the figurework and hold it in its place. The morse in hand-wrought gold, enamel and jewels was another interesting piece of ecclesiastical work.

Amongst objects destined to secular uses may be mentioned a drinking-horn, mounted in silver with an ebony base supported by the Pendragon, and a tankard with a lid bearing a conventional design of hops. The two-handled cup and cover to be presented to an eminent mining engineer is interesting as an attempt to render ornamentally a conspicuously modern theme; whilst the standard salts designed respectively for the Worshipful Company of Apothecaries and the Worshipful Company of Haberdashers, are purposely late Renaissance in character in order to be in keeping with the other plate belonging to the companies. They are quite adequate to their purpose but they are, as one would naturally have expected, far less characteristic and individual than most of Messrs. Ramsden and Carr's work.

Home Arts and Industries.—The Winter Exhibition of the Home Arts and Industries' Association is always on a smaller scale than that held in the summer, and, since it is intended primarily to attract the buyers of Christmas presents, it consists chiefly, though not entirely, of the smaller, and in a sense less important, kinds of work. It has, however, in some respects an advantage over the larger show. As there is less to be seen it is easier to see what is on view, and easier, too, for the officials of the Association so to place and group the stalls that exhibits of one kind are to be found more or less in the same place. It speaks well for the influence of the Association and for the strength of will of the class-holders that a show held near Christmas time with the avowed object of catering for the Christmas market should be as good as this undoubtedly was. Of course one or two of the stalls were covered with work which was by no means satisfactory, but on the whole a very creditably high standard was maintained. It is, of course, difficult in an Association of this kind to draw hard-and-fast rules, but one could have wished that a larger proportion of the exhibits had come from the ranks of the ordinary classes, rather than from those of what are called at the summer exhibition "partially-developed" or "developed" industries, some of which have little to distinguish them from ordinary commercial undertakings.

There was not a very large show of metalwork, but the exhibits sent from Keswick were quite satisfactory—sufficiently severe in form and well executed. Pottery was represented by figures and vases produced by the Compton Potters' Art Guild, with which Mrs. Watts is associated, and a small collection of Mr. Howson Taylor's pots. There was an exhibit of good though very modest leatherwork from Failand, Bristol, and the Fine Needlework Association sent some very dainty smocking, often carried out in very pretty colours. The most interesting embroidery, however, came from the north. Windermere sent some work in which an eminently satisfactory effect was produced without any waste of labour and was remarkable, as usual, for its bold and tasteful colouring. From Langdale came a very fine show of cut work, good both in design and execution. The success of the few pieces in blue and white ought to encourage the workers to try some more ambitious combinations of colour. The handloom weaving was largely craft pure and simple, with no pretensions to art; but there were some beautifully-coloured silks from Windermere, and the very simply-patterned woven

fabrics made at the Barclay Workshops for the Blind were in very good taste. This kind of weaving makes trimmings which are often more suitable to their purpose than embroidery. The so-called "Colonial mats," woven by the Dun Emer Guild, are in reality a very attractive version of the old-fashioned rag carpet; but the colours employed are so harmonious, and withal so clean-looking, that we hardly recognise our well-known and very dowdy old friend in her new dress.

Lace.—It was, however, in lace that the largest and most representative show was made. The lace exhibits were almost all arranged in a room by themselves, and they gained considerably by their isolation. Lace takes so much looking at that it is apt to be passed over when surrounded by work which catches the eye more readily. It was quite evident from the display made that, whatever may have been the case some years ago, at the present time there is no danger of the hand-made lace industry dying out in England. The revival seems to have affected not only one county or group of counties, but the country as a whole. English lace is a trifle dearer than that made abroad, for the standard of living is happily higher over here; but, except for motives of economy, there is really very little reason nowadays why people should buy Continental laces rather than those made at home. Quantities of lace are being made in these islands, not only Honiton, Buckinghamshire, Tambour, Limerick and Carrickmacross, but also the rather coarse kinds of Italian lace which are so popular in this country. The main centres of the industry are naturally (so far as England is concerned) Devon and Bucks, but some very good Honiton lace is being made in Norfolk, and Tambour lacemaking has for generations been carried on in Essex.

A good deal has been said in the past, and with every show of reason, about the poorness of the modern lace designs and the unintelligent way in which the traditional ones are too often copied; but it seems as though the efforts made by various individuals and societies in recent years to improve the quality, both of the workmanship and the pattern, are at last bearing fruit. There was nothing very remarkable in the way of design to be seen at Park Lane last week, but there was a good deal of work which was well balanced, well adapted to lace, and quite sufficiently attractive, and much less of the rather aimless and meaningless work that was so common only a couple of years ago. The advance is peculiarly noticeable in some of the Honiton lace exhibited, and is perhaps more marked in the pillow lace generally than in the needle-point.

The copies of old Italian metal laces from Kingston Bagpuize and Longworth, are always interesting, and the coloured silk lace is also satisfactory; but it looks as though more might be done in the way of silk lace with a certain amount of metal introduced. The difference in elasticity of the two materials may perhaps make this lace more difficult to work, but it ought to be possible to get lace which is not only effective but durable from the combination of the two kinds of thread.

EMPIRE NOTES.

British Trade Commissioners.—The visit to this country next year of the British Trade Commissioners, who were appointed by the Board of Trade to represent it in Australia and New Zealand, is likely to be of considerable interest and great service to the commercial and industrial community in the United Kingdom. The object of the Board, in arranging the visit of their representatives, is to afford to the manufacturers and merchants of London and the provinces the opportunity of consulting them on the general conditions of trade in the Australian States and in New Zealand, and of the openings there for British goods. Chambers of Commerce, and other representative commercial associations throughout Great Britain and Ireland, are being invited by the Board of Trade to arrange for these visits. It has been suggested that Mr. Richard Grigg, the British Commissioner in Canada, who has done such excellent work there, should join them. Mr. Grigg has made a close study of the industrial and commercial interests of the Dominion, and is well qualified to advise home manufacturers and merchants as to the prospects of trade in that country.

Canada and British Capital.—The field afforded in Canada for the investment of British capital has been pointed out in these columns on more than one occasion, but the subject is so important that any new light upon it is gladly welcomed. Mr. R. B. Angus, President of the Bank of Montreal, at a recent shareholders' meeting, emphasised the fact that the large influx of settlers into the Dominion, with their varied and ever-expanding needs and demands, combined with the enormous development work now in progress, offered continual opportunities to capitalists. "I am safe in saying," he declared, "that the Dominion as a whole has enjoyed a good degree of prosperity throughout the year, and that no doubt need be entertained regarding its continued growth in wealth and population in the future."

Canadian Progress.—During his recent visit to Canada, Mr. T. P. O'Connor, in the course of a series of addresses in various parts of the Dominion, said: "I have had the opportunity of seeing the great West, and all I heard and read of that wonderful region fell infinitely below what I found there. The boundless open prairie of the best wheat land in the world, through which I passed for days, revealed to me the notable fact that in Canada you have the greatest possession yet unconquered by the people and labour of the world. It is a veritable El Dorado, not requiring toil or peril of the ordinary experiences of the pioneering

settlement and cultivation, but just holding out its precious and boundless bosom to all in the world who have courage, enterprise, and hands which are willing to pick up its treasures. I found side by side with this feverish industrial activity a spirit of law-abidingness, of order, of sanity, which are the best qualities of the British character and of British institutions, and I am old-fashioned enough to feel that without this combination of restless activity and of stable society the present Canada would not be so attractive nor the future so hopeful."

Western Australian Finance.—Western Australia has been making great progress in all directions during the past year. The report of the Premier's budget speech is regarded as most satisfactory. The transactions of the previous twelve months realised a surplus of £209,000, thus reducing the deficit accumulated in former years to £102,000. The estimates of revenue and expenditure for the succeeding year show a balance which would not only extinguish the existing deficit but yield a surplus. The forecast is considered a safe one in view of the rapid advance of all industries. The speech reveals many interesting points in the State Trades' Account, concerning the railways and other reproductive public works, which, after allowing for working expenses, show a credit balance of no less than £753,802 for the year. As the interest and sinking fund payable on the public loans of the State (£22,000,000) amount to £759,443, all that the tax-payer will be obliged to pay to meet this demand will, on the present year's basis, be a trifle over £5,000 per annum. This fact is an assurance to the holders of Western Australian Stock of the soundness of their investment, and should be a guarantee of the financial standing of this progressive Australian State.

The Mono-Rail in Australia.—For many months past the mono-rail system has been a subject of discussion throughout Australia, and experiments have been carried out to test its utility as a means for securing cheap and reliable transportation. South Australia is now considering the advisability of adopting it in some parts of the new agricultural districts which are being opened up, as the cost of making roads is heavy. A special mono-rail truck is being constructed by the Government for this purpose, which promises to be a success. The estimated cost of a railway of this character is about £500 per mile, including rolling-stock. A useful example of how the mono-rail works is to be found in the forests of Burma and Siam, where elephant traction is used to convey the heavy logs of teak and other timbers to the mills or the waterways.

South African Products Exhibition.—In the spring of 1912 it is proposed to hold a South African Industrial, Agricultural and Products Exhibition at Maritzburg, Natal. It is considered that such an opportunity to attract the attention of the world's investors, financiers and buyers would be welcomed, not only by residents of that city, but by the commercial and industrial classes of South Africa generally, and that the exhibition would be of great service to the Union. Many reasons are advanced in favour of the selection of Maritzburg, as its climate, in the spring especially, is ideal, and its situation, right in the heart of the garden province, is not only one of the most beautiful in South Africa, but is easily accessible by rail and sea.

New Zealand: Preservation of the Huia.—The huia, one of the rare birds peculiar to New Zealand, is becoming rapidly extinct. In order, if possible, to prevent its utter extinction, a scheme is now on foot to find odd specimens of the breed, catch them, and place them on one of the island sanctuaries of the coast. Two Maori trappers are to be despatched to the head-waters of the Kawatau stream, a tributary of the Rangitikei River, also the head-waters of the Mangawharariki and Pohangina Rivers. It is proposed that the expedition should search round the head-waters of these rivers and along the foothills of the Tararua range. The huia is a jet-black bird, with a white band at the extreme end of its tail feathers. The feathers of these birds are much valued by the aboriginals; no Maori of importance considers himself becomingly dressed unless one or more huia feathers form part of his head-dress.

An Important Radium Discovery.—Professor Douglas Mawson, an eminent Australian scientist, who accompanied Sir Ernest Shackleton on his recent expedition to the Antarctic, made an important announcement at the last meeting of the Royal Society of South Australia. He exhibited a specimen of pitch-blende, which he had found in the course of his researches at Olary, 257 miles to the north of Adelaide. The pitch-blende discovered in this locality is a surface film, found in the cracks of the rocks. Near the surface of the ground the film is coloured yellow by the presence of Carnotite. The discovery is of greater scientific than commercial value, but is specially interesting on account of its being the first authentic find of pitch-blende in Australia. Radium, however, has been known to occur in Western Australia and Tasmania.

GENERAL NOTES.

PHYSICAL SOCIETY OF LONDON.—The Annual Exhibition of Physical Apparatus will be held on Tuesday, December 20th, 1910, in the afternoon from 3 to 6 p.m., and in the evening from 7 to 10 p.m., at the Imperial College of Science, Imperial Institute-road, South Kensington. At the exhibition a discourse on some improvements in Transmitters and Receivers for Wireless Telegraphy will be delivered by Professor J. A. Fleming, M.A., D.Sc., F.R.S., and cinematograph demonstrations of some physical phenomena will be given at intervals by Mr. R. W. Paul.

THE ENCYCLOPÆDIA BRITANNICA.—Speaking at a recent dinner to the contributors to the Encyclopædia, Mr. Hugh Chisholm, the editor, referred to the amount of practical work which the eleventh edition involved. It contained 50,000,000 words, equal to 500 ordinary books of 100,000 words each, and all of that had to be read by the editorial staff at least ten times before it assumed its final form. Considered from the industrial point of view, the eleventh edition was of great importance. It entailed the production in fourteen or fifteen months of one-half again as large an edition as the ninth, which took fourteen or fifteen years to produce. To take the India paper edition only, the actual number of volumes which would be produced in the next six months would be 1,000,000, the equivalent of 17,000,000 ordinary books, a fact which, from the industrial point of view alone, possessed some interest. The world's annual production of India paper was only 200 tons. The producers of the "Encyclopædia Britannica" gave an order for 2,000 tons, and mills in every civilised country, with the exception of the United States—where the paper could not be manufactured—had to be started to make the paper, so that the production of the Encyclopædia was a factor of some importance to industry.

POTATO STARCH-MAKING IN GERMANY.—Potatoes are the principal source of the starch manufactured in Germany, and that potato starch—known as "Kartoffelmehl"—enters extensively into the German export trade. The potatoes are first thoroughly washed, and then mashed between heavy rolling cylinders, on the surface of which there are grooves and teeth to tear up the potato cells. The starch is washed out of this ground-up pulp by means of running water. The resulting so-called "starch milk" is first drained through wire or silk screens or through perforated copper plates to remove the cell pulp, after which it is allowed to flow directly into cement settling vats or caves, or it may first be led over small, gently-sloping troughs or drains, upon which the purest of the starch then settles. The starch from the settling vats and from the settling drains is refined by being rinsed in stirring vats, and the impurities and cell substances are skimmed off. The water is then removed by special centrifugal hydro-extractors, and the resulting so-called "green starch" is generally worked up into dextrin and sugar. For producing the starch of commerce, it must be further dried in specially constructed drying chambers. The potato pulp or cell stuff, left over, is subjected to a renewal of the refining process, or it may be dried and used as cattle food.

POTATO-MEAL IN INDIA.—The development of new industries in India is always interesting, and the experiments in the manufacture of potato-meal made by Colonel Rennick, a Kulu planter, in the hills beyond Simla, have now become a practical success, the army authorities having already purchased several thousand tins as emergency army rations. Colonel Rennick has recently transferred his operations from Kulu to Narkanda, a village some forty miles beyond Simla on the well-known Hindustan and Tibet road, constructed by Lord Dalhousie about half a century ago, with the object of fostering trade with Tibet. Machinery has been procured from England, and the various buildings, works, and barracks are now approaching completion. The spot is in the centre of a tract under potato cultivation with a radius of about ten miles, while firewood is obtainable from an extensive forest called Baghi, and the railway is at a convenient distance. The potatoes, after being boiled, and peeled by hand labour, are then crushed by the engine-driven machines, prepared by a patent process, and packed in hermetically-sealed tins, each containing a pound of meal, which will cost about a rupee, and serve roughly for a week's consumption—two ounces being more than sufficient for a good meal. As a new and useful addition to the kitchen stores, it is anticipated that the potato-meal tin will find favour in many a camp.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 19...Bibliographical, 20, Hanover-square, W., 5 p.m. Mr. S. H. Scott, "Martin, Peter and Johann Schott, of Strasburg."

Geographical, in the Theatre, Burlington-gardens, W., 8.30 p.m. Dr. J. B. Charcot, "The French Antarctic Expedition, 1909-10."

London Chamber of Commerce, Oxford-court, Cannon-street, E.C., 2.30 p.m. Señor M. Zamacona, "The Economic Development of Mexico and the Possibilities of Extending British Trade with that Country."

TUESDAY, DECEMBER 20...Geographical, in the Theatre, Burlington Gardens, W., 8.15 p.m. Professor P. Geddes, "Inland Towns and Cities: their Main Origins." (Lecture II.)

Civil Engineers, Great George-street, S.W., 8 p.m. Mr. A. E. Carey, "The Winning of Coastal Lands in Holland."

Statistical (at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 5 p.m.

Photographic, 35, Russell-square, W.C., 8 p.m. Dr. W. Scheffer, "The Present State of Microscopic Research with Regard to Dry Plates."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. J. Buckland, "The Birds of the Colonies and their Preservation."

WEDNESDAY, DECEMBER 21...Meteorological, 25, Great George-street, S.W., 7.30 p.m. 1. Captain C. H. Ley, (a) "Report on Balloon Experiments at Blackpool, 1910." (b) "The Meteorological Significance of Small Wind and Pressure Variations." 2. Dr. Wilhelm Schmidt, "Atmospheric Waves of Short Period."

Geological, Burlington House, W., 8 p.m. 1. Mr. T. O. Bosworth, "The Keuper Marls of the Charnwood District." 2. Mr. R. L. Sherlock, "The Relationship of the Permian to the Trias in Nottinghamshire."

Microscopical, 20, Hanover-square, W., 8 p.m. Mr. Arthur Earland, "Modern Methods of Research on a Scientific Cruiser."

Mining and Metallurgy (at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W.), 8 p.m. 1. Mr. F. Gillman, "Malaga Magnetites." 2. Mr. R. W. Hannam, "A Method of Raising Bore-Casings from a Pontoon." 3. Mr. H. C. Bayldon, "Notes on Chilian Mills in Russia."

Journal of the Royal Society of Arts.

No. 3,031. VOL. LIX.

FRIDAY, DECEMBER 23, 1910.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 4th and 11th, at 5 o'clock, by ARTHUR MASON WORTHINGTON, C.B., M.A., F.R.S., Professor of Physics in the Royal Naval Engineering College, Devonport, on "A Study of Splashes, conducted by the aid of Instantaneous Photography."

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Members who desire tickets for the course are requested to apply for them at once.

COVERS FOR JOURNALS.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

INDUSTRIAL PYROMETRY.

By CHARLES R. DARLING, A.R.C.Sc.I., F.I.C.

Lecture I.—Delivered November 21st, 1910.

The science of temperature measurement, from the time of its inception in the seventeenth century to the present day, has proved of inestimable service to mankind. Commencing with crude instruments intended to indicate the hotness of the human body, the scope of thermometric appliances has gradually been extended by successive discoveries until, at the present time, we are able to express the temperatures of the coldest and hottest terrestrial conditions, ranging from frozen helium to the electric arc. With a less degree of certainty, we are even able to estimate the temperature of the sun, which greatly exceeds in hotness any artificial source of heat at our disposal. In the present lectures we shall only be concerned with the measurement of the range of temperatures above the limit of a mercury thermometer; and any instrument designed to indicate such temperatures we shall term a "pyrometer." Although such instruments have been in use for over a century, it is only within recent years that reliability and precision have been attained; and the perfecting of pyrometers has led to results of the highest value in many industries. Not only have many processes been improved as the outcome of researches conducted with the aid of accurate pyrometers, but, in addition, it has become possible to carry out operations at the exact temperature found by trial to give the best results. All the benefits which accrue from definiteness and certainty, as opposed to haphazard, may now be secured in furnace processes by the use of accurate pyrometers.

A brief survey of the history of the subject will form a fitting preface to the study of modern pyrometers; and it would be difficult to discover any branch of science which better illustrates the triumph of patient research over seemingly insuperable difficulties. The first attempt to record the thermal condition of a fire in terms of degrees on a thermometric scale was made by Sir Isaac Newton in 1701. A bar of iron was heated in the fire, and then removed and allowed to cool under uniform conditions. Small pieces of tin and other substances, the melting points of which had previously been determined by Newton with a linseed-oil thermometer,

were placed upon the bar, and the time taken by the bar to cool down from a red heat to the melting point of tin was noted, and also the time which elapsed between the congealing of the tin and the substances of lower melting points. Assuming that the rate of cooling of the bar was proportional to its excess temperature over its surroundings, and knowing the times and temperatures corresponding to the solidification of the substances placed on the bar, Newton calculated by extrapolation the original temperature of the bar from the time taken to cool down to the melting point of tin. The figures obtained, translated into Centigrade degrees, were 565 for a small coal fire and 620 for a fire in which wood was burnt. The law of cooling assumed by Newton we now know to be inaccurate; nevertheless these figures were much closer to the true value than those current a century later. There is no record of Newton's method having been applied in the arts for measuring furnace temperatures, for which purpose it is ill-adapted; but it is interesting to note that one of the most recent forms of pyrometer is based upon the more accurate relation since discovered to exist between the temperature of a solid and the quantity of radiant energy emitted by it. To Newton, therefore, is due the credit of first extending the thermometric scale into the region of visible heat.

It was not until 1782, however, that a practical instrument for measuring the thermal condition of a furnace, with a view to proper control, was invented. In this year Josiah Wedgwood, the famous potter, introduced a pyrometer based on the permanent contraction undergone by clay when fired, and was able, by the aid of this contrivance, to control the temperature of his furnaces more closely than had hitherto been possible. Wedgwood had found that all the care expended in the selection and working-up of his materials might be completely nullified unless the firing were conducted at the correct temperature, and had also discovered that the eye of the best-trained workman could not be trusted to judge the working temperature to the required degree of accuracy. Having observed that the amount of the permanent contraction experienced by clay when fired increased with the temperature, Wedgwood constructed a tapered gauge (Fig. 1), made in two portions, each 6 in. long. At the widest part, opposite the zero division, the width of the groove was 0·5 in., whilst the narrowest portion, which was marked 240, possessed a width of 0·3 in. Cylinders of a special clay, moulded with a flat part to rest on the bottom of the groove, were prepared, and were made of such size that, after drying, the diameter was 0·5 in. or nearly so; and hence such cylinders, when pushed down the gauge, came to rest near the zero mark. The length of the groove was divided into 240 equal parts, each 0·05 in. long, which were called "degrees." In order to test the condition of the furnace, one of the clay cylinders was introduced, and allowed

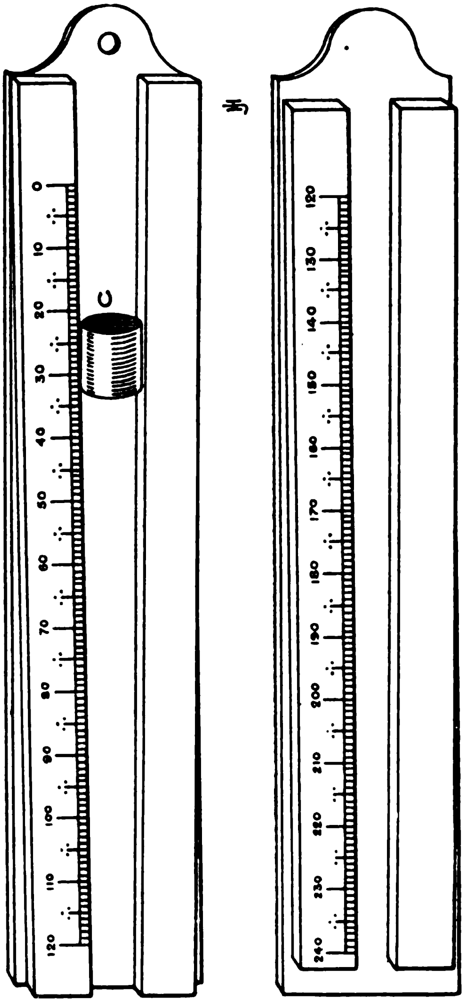


Fig. 1.—Wedgwood's Pyrometer.

to remain for a specified time; it was then removed, and, after cooling, inserted in the gauge, when the number opposite the forward end indicated the temperature in terms of Wedgwood's scale. As the correct degree for the work in hand had been discovered by previous trials, the reading obtained could be used to regulate the furnace until the proper temperature had been attained. There is little doubt that

Wedgwood's great success as a potter was largely due to the correct adjustment of his working temperatures; and time has paid a tribute to the utility of his method, which for nearly a century held undisputed sway, and has not even yet been entirely supplanted.

Wedgwood made an attempt to express the arbitrary degrees on his scale in terms of the accepted Fahrenheit degrees, and concluded that each degree was equal to 130° F. He assigned to the melting point of silver the value 4,717°, and to molten cast-iron 17,977°. These and other similar figures were generally accepted, and in tables published early in the nineteenth century the melting point of wrought-iron was recorded as 21,637° F., or 12,001° C. Considering that modern observations point to the vicinity of 1,500° C. as the correct figure, the introduction of the unit in the value 12,001 appears somewhat grotesque. The accuracy of these figures was first challenged by Daniell, who in 1822 published an account of a pyrometer based on the expansion of a platinum rod encased in a plumbago tube. Assuming the expansion of the platinum, relative to plumbago, to be uniform, Daniell obtained the figures 2,233° F. and 3,479° F. respectively for the melting points of silver and cast-iron—a difference in the latter figure of over 14,000° from that given by Wedgwood. Both these observers used the mercury thermometer for the first stages of the calibration, and assumed that the relation obtained at low temperatures held for higher degrees on the scale. The necessity for some accurate standard of temperature, with which all pyrometers could be compared and brought into agreement, thus became manifest at this early stage in the development of the subject.

Time will not permit of a detailed history of the progress of pyrometry from the time of Daniell to the present day, and only the salient features will be noted. In 1822 Seebeck discovered that if a junction of two different metals, forming part of a closed electric circuit, be heated, a current of electricity is produced in the circuit. I show this effect by taking two pieces of wire, one of iron and the other of nickel, joined at one end, and the free ends connected to a galvanometer, the moving part of which is furnished with a mirror from which a spot of light is reflected on to a scale. On placing the junction in a flame, the spot of light immediately moves along the scale, and it will be noted that the distance moved increases as the junction becomes hotter. Becquerel, in 1826, proposed to apply this phenomenon to the measurement of high temperatures, but was unable to obtain concordant results; and this experience was shared by others who afterwards worked in this direction. The cause of the early failures, and the manner in which the Seebeck effect has been successfully applied in recent times, will appear subsequently. Pyrometers based on the expansion of a gas were first suggested by Prinsep in 1828; the calorimetric method, in which the temperature of a hot substance is determined by dropping it into a known quantity of water, and noting the rise in temperature produced in the water, was patented by Byström in 1862; the optical method, in which temperature is deduced from luminosity, was first applied by Ed. Becquerel in 1863; and the resistance method, based on the increased resistance offered to electricity by a metal when heated, originated with Sir W. Siemens in 1871. All these methods are utilised at the present time.

Prior to 1886, however, pyrometers were little used in the industries, mainly for the reason that a sufficient degree of accuracy had not been attained in their indications to impress upon manufacturers the advantages to be derived from using them. The perfecting of the thermo-electric method by Le Chatelier in the year named, furnished a means of regulating high temperatures with great precision, the advantages of which were quickly recognised. In no branch of the arts is the exact adjustment of temperature of greater importance than in the working of steel, and it was to this purpose that Le Chatelier's pyrometer was first applied. In this connection, I wish to show an experiment which clearly demonstrates a remarkable property of iron and steel. Stretched across the room is an iron wire, which we will raise to a white heat by passing a powerful electric current through it. The wire, expanded by the heat, droops in the centre, and when we switch off the current, and allow the wire to cool, you will notice an interruption during the contraction and straightening of the wire. You observe that at first the wire contracts, and the centre rises; but suddenly, whilst the wire is still visibly red, it droops again, owing to a spontaneous rise in temperature which causes it to elongate; and then it straightens out gradually until cold. We might, by warming up the wire slowly, observe the same effects in converse order. If we repeat this experiment with a wire of copper, or nickel, or platinum, we notice that the cooling proceeds uniformly, and shows no break in the passage from the curved form to the straight. Professor

Barrett, who discovered this phenomenon nearly half a century ago, applied to it the term "recalescence," from the fact that the iron or steel becomes hotter without external assistance. When a large block of iron or steel is used instead of a wire, the sudden rise of temperature may easily be detected from the increase in brightness. It is a remarkable fact that none of the vast number of men engaged for centuries in the fabrication of steel articles ever observed —or at any rate recorded—this curious change, thus vindicating literally the truth of Da Vinci's aphorism, that "it is only the eye of knowledge which sees." The anomalous behaviour of iron and steel in this connection indicates that at the temperature of recalescence the internal structure of the metal is profoundly modified, resulting in the disengagement of energy in the form of heat. Other evidence of this change of structure is found in the fact that above the recalescence temperature iron is non-magnetic, but is powerfully attracted by a magnet immediately after the change has occurred. The case of steel is not so simple as that of iron, owing to the presence of carbon and other ingredients, and two or more points at which the cooling is arrested may be noted. Steel differs from iron in being capable of hardening and tempering, and these two properties are closely associated with the molecular change we have noticed. It has been found by Sir Robert Hadfield, for example, that a sample of steel containing 1·16 per cent. of carbon, when heated to a temperature just below the change point, is not hardened when quenched; but when heated a further 15° C. or 27° F. before quenching, becomes totally hard. Here is a case where the difference of a few degrees, which would escape detection by the most skilful eye, is of vital importance in determining the character of the finished product.

It will readily be seen from these considerations that an exact instrument would be of great service in the steel industry, and consequently Le Chatelier's pyrometer soon came into practical use. By its aid tests could be carried out at various temperatures which could be reproduced with certainty, and new methods of heat treatment were thus discovered. Other industries were not slow to recognise the value of precise temperature control; and every year since 1886 has seen the continued extension of the use of pyrometers. Various new instruments have been invented and found a successful application, until at the present day the manufacture of pyrometers has become an important industry in itself. Now, it is evident that all pyrometers, of any pattern, ought to give identical readings under the same conditions of temperature; and this entails the use of a standard of reference. The best practical standard is furnished by the "gas" pyrometer, as its readings are in close conformity with the absolute or thermodynamic scale of temperatures. We are able, by means of measuring the increase in volume or pressure of a gas to obtain a scale of temperatures, which we shall call the "gas scale." If, for example, we measure the volume of a gas such as hydrogen when surrounded by ice, and also when surrounded by steam at 760 mm. pressure, we find the ratio of the two volumes to be expressed by the fraction $\frac{273}{373}$. If we agree to call the temperature interval between ice and steam 100° C., we may state that the gas expands by $\frac{1}{273}$ of its volume at 0° C. for each degree rise in temperature. We may extend this scale indefinitely; thus the temperature at which the volume is doubled would be 273° C., when trebled 546° C., and so on. This procedure would be difficult to carry out in practice, and we may instead rely upon the fact that if the gas be prevented from expanding its pressure increases, so that at 273° C. the pressure is double that exerted by the gas at 0°, and at 546° C. three times as great. This is the principle of the constant volume gas thermometer, in which the gas is prevented from expanding by raising a cistern of mercury, the height of the column of mercury thus becoming an index to the temperature of the gas by measuring its pressure. In applying this instrument to the measurement of high temperatures, it must possess a bulb which is not distorted by heat, even under high pressures, as otherwise the volume would alter and consequently the pressure. In its latest form the standard gas pyrometer is furnished with a bulb made from an alloy of platinum and rhodium, containing 20 per cent. of the latter metal. In order to prevent distortion at high temperatures, the bulb is enclosed in a space in which the pressure is maintained at the same extent as that of the gas in the bulb. Nitrogen gas is used as the thermometric substance, as hydrogen escapes through hot platinum. By the aid of this instrument temperatures as high as 1,550° C. may be read with certainty; but beyond this point the bulb becomes too soft and alters in shape by its own weight. The gas pyrometer described, however, is too cumbersome for everyday use in the workshop, and is only employed to fix standard points for the calibration of more convenient instruments. It

is merely a standard of reference, which enables all other pyrometers to be made to agree in their readings. In order to give practical effect to this standardisation, a number of fixed points have been determined with great precision by various observers. These are indicated in the table before us :—

until at the present day we have reason to believe that the greatest possible error on the gas scale, at 1,550° C., is not greater than 2°, and that pyrometry, therefore, may claim to rank as an exact science.

I now pass on to a description of the various pyrometers in use at the present time, and

TABLE OF FIXED POINTS.

Substance.	Physical Condition.	Deg. Centigrade.	Deg. Fahrenheit.
Water (ice)	At Melting Point	0	32
Water	,, Boiling ,,	100	212
Aniline	,, ,, ,,	184	363
Naphthalene	,, ,, ,,	220	428
Tin	,, Melting ,,	232	249

Palladium	,, ,, ,,	1540	2804
Platinum	,, ,, ,,	1753	3187

In making a temperature scale for a pyrometer of any kind we are at liberty to take any suitable fixed points from the table, and, having inserted the pyrometer in the substance and allowed the physical state specified to be realised, we may mark the scale of the pyrometer with the temperature indicated for the substance. We may thus obtain a number of points on the scale of our instrument, and afterwards subdivide the space between the points in an appropriate manner. All pyrometers may thus be made to agree with each other and with the gas scale. It must be remembered that above 1,550° C. direct comparisons with the gas scale are not yet possible, and any value exceeding this is derived by a process of extrapolation, and possesses the uncertainty which always attaches to such procedure.

I have thought it advisable to deal thus early with the method of standardising pyrometers, in order to emphasise the fact that only by reference to a single accepted standard can all the various types be brought into harmony. The figures used in the workshop are thus the product of years of patient labour in the research laboratory, by means of which the discrepancies of gas pyrometers have been eliminated one by one,

propose to give an account of the underlying principle in each instance, and to mention the special uses and limitations of each type. And in order to clear the way for the examination of the more complicated patterns, we will deal first of all with a miscellaneous set of devices of a simple character which are found useful in numerous operations. We will commence with

CALORIMETRIC OR WATER PYROMETERS.

When a metal of known weight and specific heat is raised to a high temperature and plunged into a known quantity of cold water, the rise in temperature of the water may be used to calculate the original temperature of the piece of metal. If, for example, 100 grams of a metal of specific heat 0·1 were taken from a furnace and dropped into 500 grams of water at 5° C., which thereby becomes heated to 25° C., we may proceed by equating the heat lost by the metal to that gained by the water, thus :—

$$100 \times \cdot 1 \times (t - 25) = 500 \times (25 - 5)$$

and t, the temperature of the hot metal, is 1,025° C.

I have here the earliest instrument of this type, as made by Byström. It consists of a

zinc vessel, lagged with wood, to hold the water; and a metal cage, dipping under the water, to contain the lump of hot metal, which was a piece of platinum. A thermometer, passing through a hole in the lid, served to indicate the rise in temperature. This instrument was in use in the Royal Arsenal, Woolwich, in 1863. A later type, which is shown in the diagram

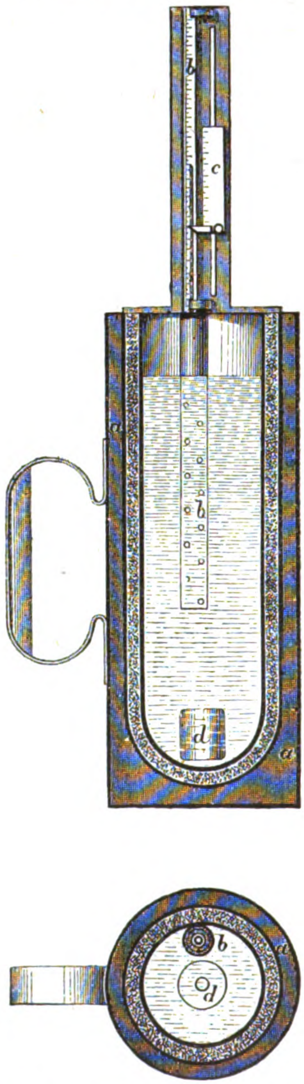

Fig. 2.—Siemens' Water Pyrometer.

(Fig. 2), and of which we have an example on the lecture table, is now sold by Messrs. Siemens Bros. and Co. The water is contained in the inner of two concentric vessels, the space between being filled with non-conducting material, and the outer vessel furnished with a handle for convenience in holding. Cylinders of metal, of known weight, are provided; copper, iron, or nickel being available according to the wish of the user. To avoid the necessity of calculation, a scale is fixed at the side of the thermometer, from which the temperature of the hot metal may be read off by noticing the mark opposite to the top of the mercury column in the thermometer after quenching. In this form the water pyrometer may be used by workmen unskilled in calculations, and the manipulation is of the simplest character.

We will now consider how the temperatures indicated by the water pyrometer may be made to agree with temperatures on the standard gas scale. As will be noted from the calculation, everything depends on an accurate knowledge of the specific heat of the metal used; and as the specific heat of metals generally increases as the temperature rises, it is necessary to know this value accurately for the range comprehended by the instrument. Numerous experiments, conducted at various temperatures measured on the gas scale, have furnished the information required; and by using the figures thus obtained in marking the temperatures on the scale of the pyrometer, an instrument based upon the accepted standard is secured.

The advantages possessed by this instrument are low prime cost and simplicity in use. A great drawback, however, is that a special experiment has to be conducted whenever it is desired to know the temperature of a furnace, involving time and labour; in which respect the water pyrometer is distincly inferior to other types which give a continuous indication which may be read off on a dial. The accuracy of the results depends to some extent on the observer, who may fail, for example, to allow the lump of metal time to attain the temperature of the furnace; or may delay the transit of the hot metal to the water. Taking all the possible errors into account, the closest approach to accuracy which may be expected under working conditions is represented by nearly 20° C. or 40° F., and hence the water pyrometer cannot be applied in cases where an error of this extent is of importance. It finds many useful applications, however, in processes which may be conducted successfully over a fairly wide range of temperature, and in which an occasional determination of the state of the furnace suffices.

Fusion Pyrometers.

A simple method for obtaining casual readings of the temperature of a furnace is to insert a number of substances of progressive melting

points, and to observe which have been melted and which have survived. For example, a series of salts, such as the following, may be taken, and a small portion of each placed on a plate and inserted in the furnace :—

Salt.	Melting Point. Deg. C.	Deg. F.
1 molecule common salt + 1 molecule potassium chloride	650	1202
Common salt	800	1472
Anhydrous sodium carbonate ...	850	1562
,, ,, sulphate ...	900	1652
Sodium plumbate	1000	1832
Anhydrous potassium sulphate	1070	1958
,, magnesium sulphate	1150	2102

On withdrawal from the furnace, inspection of the plate will show which of the salts has fused, and the temperature may then be approximately determined. If, for example, the first

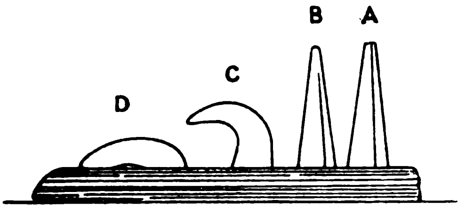

FIG. 3.—SEGER "CONES."

five in the above list were found to have melted, whilst the last two were intact, the temperature would lie between 1,000° and 1,070° C. The precision of the method evidently depends upon the interval between the melting points of the substances used, and recently Brearley has prepared a special series of salts which enable definite temperatures to be approximated closely by this means. These salts are made up into the form of small cylinders, each being labelled with its proper melting point, and are sold under the name of "Sentinel" pyrometers. A specially-prepared series of alloys is sometimes employed instead of salts; but the most accurate development of the fusion method is due to Seger, of Berlin, who produced clays of varying composition with melting points ranging from 590° C., or 1,094° F., to 1,890° C., or 3,434° F., no interval being greater than 30° C. For convenience in observation, these clays are shaped into triangular pyramids, as shown at A, Fig. 3. Several pyramids, possessing melting points judged to approximate to the temperature of the furnace, are inserted, with the result shown in the figure, where D is seen to have collapsed, C has bent over, B has become rounded at the summit, whilst A is intact. The temperature of the furnace corresponds to the melting point of C, and is read from a table which records the melting points of the pyramids with reference to the number stamped on each.

In order to furnish the same figure as would be obtained by other methods, the melting points of the materials used must be correctly known in terms of the gas scale. The method is simple and cheap, but suffers from the disadvantages that only intermittent readings can be taken, and that slight variations in the compositions seriously affect the melting points.

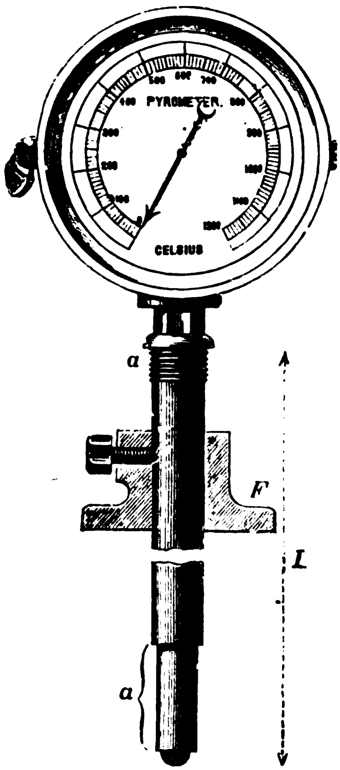

FIG. 4.

MISCELLANEOUS APPLIANCES.

Approximate measurements of high temperatures may be obtained by measuring the expansion of an iron bar encased in a fireclay tube, or of graphite in an iron tube, of which Fig. 4 is an example; or by enclosing mercury in a steel tube to which a pressure-gauge is connected, pressures being translated into corresponding temperatures by comparison with an accurate pyrometer. Both these methods are in use, but are not of sufficient importance to call for detailed description in the present lectures. Pyrometers based on the rise in temperature of

water or air, when forced through a tube placed in the furnace, have occasionally been used, and may possess a fair degree of accuracy; but are usually complicated compared with the generally recognised methods. The same remarks apply to instruments depending upon the altered viscosity of gases, or upon the change in refractive index. With this passing mention, we shall proceed to descriptions of the pyrometers which have been successfully employed for work of precision in various industries.

[The following instruments were exhibited:—

1. A calorimetric or water pyrometer, by Messrs. Siemens Bros. and Co., Ltd.

2. A plumbago expansion pyrometer, by Messrs. A. Gallenkamp and Co., Ltd.

3. A mercury-pressure pyrometer, by Messrs. A. Gallenkamp and Co., Ltd.]

THE CHRISTMAS TREE.

By Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.

> The Tree of Life,
> The middle tree, and highest there that grew.
> —Milton, *Paradise Lost*, iv. 194, 195.

Part I.

Only during the past fifty to sixty years has the fashion become prevalent in England of setting up "The Christmas Tree"* as a Yuletide decoration, and a most delightful vehicle for showering down gifts upon the young, in connection with domestic and public popular celebrations of the joyous Christian Festival of the Nativity. It is said to have been introduced among us from Germany,† where it is regarded as indigenous; and is probably a survival of some observance connected with the pagan Saturnalia of the Winter Solstice, in supersession whereof the Church, about the fifth century of our era, instituted Christmas Day. It has, indeed, been explained as being derived from the ancient Egyptian usage of decking houses at the time of the Winter Solstice with branches of the date palm, as the symbol of life triumphant over death, and therefore of perennial life in the renewal of each successive bounteous year; and the supporters of this suggestion point to the fact that pyramids of green paper, covered all over with wreaths and festoons of flowers, and with strings of sweetmeats, and other presents for children, are often substituted in Germany for "the Christmas Tree." But similar pyramids, together with similar trees—the latter usually altogether artificial, and often constructed of the costliest materials, even of gems and gold--are carried about at the marriage of Hindus in India, and at other of their religious processions, such as the Hoolee [Holi] or annual procession of the Vernal Equinox. These pyramids represent Mount Meru, and the Earth, and the trees, the Kalpadruma, or "Tree of Ages," and the fragrant Parajita, the "Tree of every Perfect Gift," growing on the slopes of Mount Meru; while in their enlarged sense they symbolise the constellated splendour of the outstretched spacious heavens, as of a tree deep-rooted in the earth, and laden with golden fruit. Both the pyramids and the trees are also phallic emblems of life, individual, and terrestrial, and celestial. Therefore, if a relationship exists between the Egyptian practice of hanging houses at the Winter Solstice with branches of the date palm, and the German, and now widespread English custom of using gift-bearing and brilliantly-illuminated evergreen trees (nearly always firs) as a Christmas decoration, it is most probably due to collateral rather than to direct descent; and this is indeed indicated by the fact of Egyptians having regarded the date palm as an emblem not only of immortality, but also of the starlit firmament on high.

The Hindus derive the origin of their race from Idavarsha, the "Enclosure," or "Garden of Ida," the wife of Manu,* and the Mother of mankind. Here they place their Olympus, the fabulous Mount Meru, the centre and culminating point of the earth, and the support and pivot of the heavens. Its slopes collect the celestial Ganges, that is, the dews and rains of heaven, and run them off into the lake Manasasarovara, "the most excellent lake of the Spirit." The terrestrial Ganges, having its reputed source in this lake, as it circles seven times round Mount Meru, forms the four lesser lakes wherefrom the four rivers of Idavarsha flow out into the four quarters of the world; and it is about the fountains of these four rivers that the Hindus place the sacred Kalpadruma and Parajita trees already named. Mount Meru, regarded geographically, may be localised in the Himalayan regions about the Pamir steppe; but it is

* Cassel, P. "Weihnachten, Ursprunge, Brauche u. Aberglauben," Berlin, 1862. 8vo.

† It is said in Cassell's "Household Guide," vol. i. p. 151, to have been first introduced into England in the household of George IV. by a German servant of Queen Caroline's. Reference is also made in this work to a tree of gold, set before Henry VIII. during some Christmas pageants at Richmond.

* The "Thinker," *i.e.*, Man.

quite impossible to identify the Kalpadruma and Parajita trees with any known botanical species; and they are merely mythical "Trees of Life," the idea of them being inspired by the primitive worship of trees as phallic divinities.

The traditions of the ancient Persians* place the scene of the creation of man in the Aryana-Vaego. In the first Fargard of the Vendidad, it is the first-named of the sixteen good lands, said to have been created by Ormazd (Ahuramazda), and afterwards cursed by Ahriman (Angra Mainyu). In the second Fargard it is described as the country of the first man, "the fair Yima." Under his golden rule 300 winters passed away therein; when, being warned that it had become over full of the blazing fires of human homes, and of herds and flocks, he, with the assistance of "the Genius of the Earth," extended its size to one-third more than it was at the first. Thus another 300 years passed away; whenafter he again enlarged it another third; and this process was again repeated, so that the Aryana-Vaego became double its original size. Then Ormazd called all the celestial gods together, and "the fair Yima" with them, and warned them that there were about to fall on the earth "the final winters" of fierce, foul frosts, with "snow fourteen fingers deep," before which all their flocks and herds would perish, alike those grazing over the open plains, and those that fed in the deep bosoms of the leafy dales, and those that were sheltered within the stables of their homesteads. Therefore, Yima was directed to make a four-square *vara*, or "Enclosure," two miles long on each side, and to bring into it "the seeds of men and women," "the bravest and best, and fairest on the earth," and "the seeds of fire," and of sheep and oxen and dogs; and to settle them by the green banks of the fountains of living waters that sprang up within the *vara*, and to establish therein this renewed dwelling-place of men. All this the fair Yima did; and then he sealed up the *vara* with a golden signet ring, and made a door to it, and a window, "self-shining within." None that was deformed, or diseased, or a lunatic, or that was imbecile, or impotent, or a liar, or that bore any of "the brands of Ahriman," might enter into it. But the men and women admitted within the *vara*, lived the happiest life there, and they never died, but dwelt there for ever in the presence of the Eternal Glory. In the Zend-Avesta references are also made to the Hara-Berezaiti, "the Heavenly Mountain" of Aryana-Vaego, whereupon the crystalline expanse of the heaven rests, and wherenigh the sun rises; and to the bridge Kinvad, "the Straight" [Sirat], "The brig o' Dread, na brader than a thread," stretching from the Hara-Berezaiti over Hell to Heaven; and to the "Tree of Healing and Immortality," "the White Homa Tree," called also Gaokerena, that grows by the head-springs of the Ardvisura fountain; and to the two rivers, the Arvand and the Daitya, flowing from this source, and replenishing all the rivers and seas of the earth. According to the latter Pehlvi texts, on the White Homa Tree sits the Säena bird [*cf.* Simurg] and shakes down from it the seeds of life in man, and beasts and birds and fishes and plants, that, as they fall, are at once seen by the bird Kamros, as it watches for them from the top of the Hara-Berezaiti mountain, and are carried off by it, and scattered far and wide over the world. The tree is protected by ten fishlike monsters, having their dwelling in the Ardvisura lake.

In these details we have the same mixture of mythical and actual geography as in the Puranic descriptions of the Idavarsha. Thus the Aryana-Vaego, although it refers to the original starting-place of the Iranian Aryas in Central Asia, is also an ideal country, in some of its aspects an earthly Paradise, and in others an Elysium, ruled over by Yima; who, as the first of men to die, is also the personification of death. Among the Persians he always remained, even as Death, the first bright consummate flower of humanity gathered by the grave, the gentle King of the sinless dead; but in Hindu mythology he becomes deformed into the terrible Yama, the god of Judgment and Hell. The Aryana-Vaego, therefore, is at once the original seat of the Iranian Aryas in High Asia, the Elysium of their departed ancestors, and the legendary Eden of the Aryan, and, indeed, of all the Caucasian races. The White Homa tree has always been botanically identified with the *Sarcostemma viminale*, or Soma plant; and I have always also included under it both the vine and the date palm*; but in its highest significance it is, like the Kalpadruma and Parajita trees, the poetical symbol of cosmical life. The original Hara-Berezaiti, and the Arvand and Daitya rivers, must be identified with the Hindoo Koosh or Parapanisus range, and some of the streams flowing from it; but their names, like

* "Sacred Books of the East," edited by Professor Max Muller, vol. iv.; "The Zend-Avesta," part i.; "The Vendidad," translated by Professor James Darmestetter, Oxford, 1880.

* See my Appendix on the Homa Plant, to Max Muller's "Biography of Words."

that of Mount Olympus, reappear again and again, variously modified, in the course of Aryan migration westward; that of the Arvand river being found as an appellation of the Elwand mountain, the Mount Orontes of classical geography, in Media, and of the River Orontes in Syria. The Hara-Berezaiti mountain, both in this primitive form of its name and the later form of Alborj, has undergone still more frequent displacements from east to west; its name having been successively attached to the Elburz mountains east of the Caspian Sea, to the Elburz mountains south of the Caspian, and to the Elburz mountains of the Caucasus. In the Assyrian inscriptions it is attached, in the slightly altered form of Allabria, to the Gordyæan, or Kurdish mountains, and it is on the latter, under the name of Lubar, that St. Epiphanius places "Noah's Ark." The name of Baris, assigned by Nicholas Damascenus to Mount Masis [Aghridagh] in Armenia, usually identified by Christian writers with the *hara-Ararat* ["the mountain of Ararat"] of Genesis viii. 4, whereon, according to the Bible, Noak's Ark rested after the Deluge, is supposed to be a direct corruption of Berezaiti. This primitive Iranian name certainly appears almost unaltered in that of Mount Berecynthus in Phrygia, the abode of the Great Earth-Mother, Rhea-Cybele. And wherever it travelled and became fixed, there, we may be sure, was carried and planted the ever-green legend of "the Tree of Life."

The legends of the Norse people, or Aryas of Northern Europe, also point to the colossal circle of the Caucasian range, stretching from the confines of China to the shores of the Black Sea, and beyond them, until it ends at Cape Finisterre in Spain, and the Atlas Mountains of Morocco, as the earliest cradle* of the human race; for Börr, who in their primitive mythology is the common progenitor of gods and men, is but a personification of these mountains. As-gard, that is "God's-ward," while mythologically the starry firmament ["flammantia mœnia mundi," "The Citadel of Chronos"], is geographically and historically Azov, "The Ward of the Asir." The Norse Olympus rises from the centre of Mid-gard, "The Middle-ward," the residence of mankind, separated by the circumfluent ocean stream from Ut-gard, the "Outer-ward" of the Jotuns or "Giants." Below Mid-gard is the shadowy underground world of the dead, Niflheim. From the centre of Mid-gard, and the summit of As-gard, springs the "Ash-tree," Yggdrasil, with branches spreading out over the whole earth, and reaching above the highest heavens, and three great roots going down into the lowest Hell, where lies coiled round them the serpent Nidhögg, "The Gnawer," Death, who, like the serpent Anunta of the seventh Hell of the Hindus beneath Mount Meru, typifies not only death, but the subterranean volcanic forces whereby the destruction of the world itself is ever threatened. Here the Paradisaical Yggdrasil is transparently a symbol of the universal life and joy and glory of Nature.

The inhabitants of Mid-gard are said to have been created by Odin, and his brothers Wili and Wi, from two pieces of wood, one of ash and the other of elm; the first being changed into a man called Askär—*i.e.*, Ash, and the second into a woman called Embla, *i.e.*, Elm. It will be remembered that the Greeks derived "the third race of men," who may be identified with the Aryas of the Bronze Age of Europe,* "from the ash-tree" [ἐκ μελιᾶν, Hesiod, "Works and Days," 144]. They also made the Caucasus mountains "the midmost part of the earth," "the beginning and the end of all things" [Hesiod, "Theogony," 738], the seat of the punishment of Prometheus, the son of Iapetus or Japheth, the mythical leader of the Aryan immigration into Europe.† Mount Olympus in Thessaly was the abode of the gods of Greece, according to Homer, and until the later poets translated them to the sky; but wherever the Greeks went they carried with them the name of this mountain, localising it in Bithynia, Mysia, Lycia, Lesbos, Thessaly, Elis, Laconia, and Cyprus; thus also unconsciously associating the original habitat of their race with some alpine region at the initial point of the line of their exodus from the East.

The Semitic traditions ‡ differ from the Aryan in distinguishing between the birthplace of the human race, Gan-Eden, "the Garden of Eden," and the mountain whereupon Noah's Ark, containing the forefathers of the renewed human race, rested after "the Deluge." Every tree pleasant to be seen and useful for food grew therein, and

* That is, earliest within the memory of man: for we must distinguish between the several historical Edens and the ethnographical centre, or centres, of the evolution of the human species.

* "Their houses brass, of brass the warlike blade,
Iron was not yet known, in brass they trade."
—Hesiod, *Works and Days*, translated by Cooke.

† Of course, Prometheus is a Sun-god also, and, therefore, naturally associated with the Caucasus mountains, as the starting-point, viewed from the West, of the sun's daily course round the globe.

‡ "Les Origines de l'Histoire d'après la Bible," par F. Lenormant.

"the Tree of Life," and the "Tree of Knowledge of Good and Evil." It was watered by a river that, after flowing through Eden, was parted into four heads. There can be no question of Sir Henry Rawlinson's identification of the Eden of Genesis ii. with the Gin-Dunish of an inscription of Assurbanipal or Sardanapalus, *circa* B.C. 668–40; that is, with the country surrounding the city of Babylon, watered by the Pallacopas [Pishon], Shat-el-Nil [Gihon], Tigris [Hiddekel], and Euphrates [Perath].* This district was familiarly known to the Babylonians as Gan-Dunias, "the garden of (the god) Dunias"; and the city of Babylon itself was known also by the name of Dintira, or Tintira, "the Divine Tree"; as the counterpart of the cosmic "Tree of Life," so often represented guarded by a cherub on either side on Babylonian gems and the "Nineveh marbles." More recently Sir Henry Rawlinson has identified the special spot wherein the terrestrial site of "the Tree of Life" was originally localised with the town of Eridu, the oldest seat of the worship of the Akkadian earth-god Enki, the Assyro-Babylonian Hea.* Nevertheless it is evident that the Garden of Eden is also the same mythical Paradise as the Idavarsha of the Hindus, and the Aryana-Vaego of the Iranian Persians, and the Asgard of the Norse, but localised in Mesopotamia by the Semites (as long before them by the Hamitic race), after they had forgotten their primordial Caucasian home in High Asia, or preserved the memory of it only in the tradition of a fabulous garden watered by a heavenly fountain, the source of all earthly streams. Then, as the Semites overspread Anterior Asia, and their survey of the countries surrounding them was enlarged, their conception of Gan-Eden was extended, like that of the Hindus of Meru, over the whole habitable world known to them, as encircled by the Oxus-Indus or Pishon, and the Nile-Indus or Gihon, and traversed by the Tigris and Euphrates.

Assyriological science—of which, in succession to its illustrious founder, Sir Henry Rawlinson, Mr. Sayce, the brilliant Deputy-Professor of Philology at Oxford, has long been the active exponent—has demonstrated in the fullest detail that the Biblical myth of Eden was borrowed from the cuneiform, brick-inscribed, literature of the Akkads, or primitive Chaldæans, a Scythian or Turanian people allied to the modern Turks; who, if they were not the actual aborigines of Lower Mesopotamia, were the first to establish themselves in that country during the period of the universal preponderance of the Scythians in Anterior Asia, and to lay there the foundation of the characteristic Hamito-Semitic culture of the Assyrian and Babylonian Empires, to which the nascent religion and arts of Europe are more directly, and far more intimately indebted than even to the civilisation of ancient Egypt. The Hebrews were probably vaguely acquainted with the myth from the time when Abraham went forth from "Ur of the Chaldees," "to go into the land of Canaan," and after the Captivity they must have become thoroughly familiarised with it.

Monotheism is, indeed, conjectured to have originated among the earlier Semitic immigrants into Chaldæa, who settled in the city of Eridu, whence it is supposed to have been communicated to the Iranian Aryas of Persia in the east; and is known to have been carried westward

* It is deeply interesting to find that, just as the Hindus try to reproduce Mount Meru everywhere, and in almost everything, so the Jews would seem to have endeavoured to repeat the geography of the fabled Eden in the plan of the city of Jerusalem, regarded by them as the centre of the earth [Ezekiel v. 5]. The city was watered by four streams, one of which always continued to be called Gihon [1 Kings i. 33, 38], and they were reputed to issue, through underground channels, from the fountains of fresh water beneath the Temple, whereto the Jews attached the profoundest sanctity [Ezekiel xlvii. 1–12, Joel iii. 18, Zechariah xiii. 1 and xiv. 8]. This sacred spring was associated, like the mythical Ganges and Arvand and Daitya, with a mountain the Jews called Moriah, identified by Lenormant, following the generally hazardous guidance of Wilford, with Mount Meru. Milton includes an anonymous mountain in his description of the Garden of Eden, "Paradise Lost," iv. 223–235:—

"Southward through Eden went a river large,
Nor changed his course, but through the shaggy hill
Passed underneath engulfed; for God had thrown
That mountain, as His garden mound high raised,
Upon the rapid current, which through veins
Of porous earth with kindly thirst updrawn,
Rose a fresh fountain, and with many a rill
Watered the garden, thence united fell
Down the steep glade, and met the nether flood,
Which from his darksome passage now appears,
And now divided into four main streams,
Run diverse, wandering many a famous realm,
And country, whereof here needs no account."

On this passage Bishop Newton observes:—"The river that watered the Garden of Eden was, we think, the river formed by the junction of the Euphrates and Tigris, and this river was parted into four main streams or rivers: two above the garden—namely, Euphrates and Tigris, before they are joined—and two below the garden—namely, the Euphrates and Tigris, after they are united again." This is the very conclusion forced on us by modern topographical researches in Mesopotamia; and that Newton should have so exactly anticipated them shows the great value of holding on hard by tradition in the investigation of such obscure questions of the archaic history of mankind.

* The neighbourhood of Kurnah, at the confluence of the Tigris and Euphrates in the Shat-el-Arab, about 100 miles from the head of the Persian Gulf, has always been regarded by its present Arab inhabitants as the site of the terrestrial Paradise (Persian *fir-dauz*, "a garden," Sanscrit *para-desa*, "far country"—of fancy), a remarkable proof of the credibility of the ethnical legends, and historical traditions of the immutable East.

into Syria by the Jews, through the instrumentality of whose Sacred Scriptures it has become naturalised over all Christendom and throughout Islam. If, therefore, Eridu was the original seat in Mesopotamia of the monotheistic sect of primitive Semites, their descendants, including the Hebrews, might well, for that reason alone, have for ever associated the place with the primæval Paradise of the human race.

But long anterior to the advent of the Semites in Eridu, it would seem to have been the centre of worship of the Akkadian earth-god Enki [Earth], called Hea by the Assyrians and Babylonians, who was also the double personification of the prehistoric introduction of civilisation into Mesopotamia, and of the sun in his southern course through the Indian Ocean: just as Dionysos, "the Assyrian stranger," is the double personification of the westward course of the sun, and of Phœnician commerce and Chaldæa-Assyrian civilisation, through the Mediterranean Sea. He was the great "deus averruncus" of the Chaldæans, who alone possessed the dread secret of the incommunicable name of "the great gods" of the seven planetary spheres, the mere threat of the utterance of whose name compelled the submission of the whole impious array of the demoniacal spirits of the underground world. As "Lord of the World" his wife is Davkina, a female deification of the earth; as "Lord of the Abyss [*absu*]," and the "Lord of Saliors," his wife is the goddess Bahu, *i.e.*, Chaos [*bohu* of Genesis i.], while as "Lord of the Great Land," *i.e.*, Hades, the land of the dead, he is associated with the goddess Mylitta or Ishtar, under her chthonian title of Ninkegal. Like Dagon, the fish-god of the Philistines, he is represented as a merman; and also as sailing with all "the great gods," in a glorious ark of cedar wood, over the black water of the traditional Deluge, a myth, as I believe, of the south-west monsoon of the Indian Ocean.

His attributes are the Arrow Head, symbolising the invention of cuneiform writing, ascribed to him; the Serpent, symbolising his general civilising influence, worshipped in the garden at Eridu in connection with "the Tree of Life"; and the Disc of 50 fiery spokes, obviously derived from his character as a Sun-god; and recalling to mind the *chakra* of the Hindu gods, and "the Flaming Sword" of the Cherubim in the Biblical account of the Garden of Eden, "which turned every way, to keep the way of the Tree of Life."

On the Assyrian sculptures the sacred Tree of Life is associated also with the symbols of Asshur, who gave his name to, or took it from, Asshur, now Kilah Sherghat, the first capital of the Assyrians. He was originally no more than the eponymous progenitor of their race, the second son of Shem, but was afterwards identified by them with the supreme God Il [*cf. Allah*] of the Babylonians, and substituted for him as head of the official pantheon of Assyria. He is usually figured in the form either of the Winged Solar Disc ["the Sun of Righteousness with healing in his wings," Malachi iv. 2], or a Dove, the prolific white dove of Syria, a universally recognised symbol of the active or generative reproductive power of Nature; the Almighty being still believed throughout Anterior Asia to manifest Himself in the form of this bird.

Frequently the Sun Disc is represented as shining down upon, or the Dove as overshadowing, the *ashera* ["grove" of Old Testament, A.V.], or conventional representation of the Tree of Life; the Dove in this connection being supposed to typify Nana, Mylitta, or Ishtar, the common wife of all the Assyrian and Babylonian gods, rather than Sheruba, the shadowy special consort of Asshur. She was the only goddess known to the original Akkadians, their universal Earth-Mother, by whose divisional deification, and duodecimal distribution, the Assyrians and Babylonians, who were very uxorious in their notions, managed to provide a separate wife for each of their twelve greater gods.* But Nana always remained among the pagan Semites of Anterior Asia the highest and only really individualised personification of the passive, or receptive reproductive power of Nature, into whom all the other goddesses, formed by the merely nominal reduplication of herself, are at once resolvable. She is regent of "the brilliant star" Venus, and, as her proper self, of the month Ululu —August-September—of which the Akkadian sign was the Virgin. Friday also, the seventh day of the Akkadian week, was especially sacred to her, and to marriage, over the rites of which she [*cf.* Lucina of Romans and Ilithyia of Greeks] presided; wherefore the early Christians held this day of evil omen and accursed, a superstition still carefully observed among the seafaring populations of the Mediterranean, by whom, in archaic times, she was regarded as their "divinest patroness and midwife." As

* These "wives" are but poetical figures, images, "idols of the nation or tribe" of their worshippers, and simply signify the feminine force, or energy [or *sakti* as the Hindus term their goddesses] of the gods. Compare Ausonius, "De Deis":

"Tum Iovis et Consi germanus, Tartareus Dis.
Et soror et conjux fratris, regina deum, Vis."

the planet Venus appears sometimes as "the Morning Star," and sometimes as "the Evening Star," so Nana was correspondingly distinguished by the Assyrians as "Ishtar of Arbela," "the Goddess of War," and "Ishtar of Nineveh," "the Goddess of Love." In her chthonian aspects she is the Assyrian Allat ["goddess"], after whom Queen Dido is called Elissa [Eliza]. Indeed, the story of Dido, whose sister Anna became deified among the Romans under the name of Anna Perenna,* is supposed to be a myth of the introduction of the worship of Venus into Italy. She is also the Arabian Venus, called by Herodotus Alitta and Alilat, and by the modern Arabians *al* Lat, who, with the goddesses *al* Uzza† ["the Mighty One"], and Manat, "the three daughters of God," was worshipped in Arabia, before the time of Mahomet, under the various forms of graven images and phallic stones and trees; and it is not impossible that the *stambhas*, or inscribed "posts," presumptively of phallic origin, set up by the Buddhists in ancient India, and now represented by the *dipdans*, or "lustral" columns placed before Hindu temples, may have derived their more usual name of *lat*, "a pillar," from the Arabian goddess Alilat. The Muslims have always identified the phallic stone [*lingam*], destroyed by Mahmoud of Ghazni at Somnath, A.D. 1024, with the goddess Lat of Arabia. In the East, Nana or Ishtar is again the Phœnician Astarte, the Canaanitish Ashtoreth, so often named in the Old Testament in connection with the *asherah* [in plural *asherim*], or conventional image of the Tree of Life, and the Atargatis of the Phœnicians, whose worship was diffused by them all over Asia Minor; where the priestesses who served her in her double capacity of "Goddess of War" and "Queen of Love," were the martial courtesans known to the Greeks as the mythical Amazons. Their name is usually said to be compounded of α privative and μαζός "the breast," because according to the professed explanation of this absurd etymology, they deprived themselves of the right breast that it might not interfere with the use of the bow. But more probably it was derived from the endearing Aramaic title of *Um* or *Umu*, given generally to the consorts of the Assyro-Babylonian gods, and particularly to Nana, or Ishtar, who was worshipped under this very appellation, as Um-Uruk, "the [chthonian] Mother of Uruk," at Erech, the great necropolis of Chaldæa, and in its Aryan [Iranian] form of Ma-bog, "Mother of the Gods," at Hierapolis, or Bambyce, now Balbec, in Syria, and again of simply Ma, "the Mother," at Komana in Cappadocia, and Pessinus in Phrygia. Her Amazons may be compared with the Ambubaiæ, or Syrian dancing girls of the Roman circus, and with the Bayaderes or dancing girls of the sacred* Basvi, Bhavin, and Mahari castes in India, whose Amazonian character I pointed out in the "Handbook to the British-Indian Section of the Paris Universal Exhibition of 1878." About B.C. 500, Nana was introduced into the pantheon of the corrupted Zoroastrianism of Persia under the name of Thanata, Anæa, or Nanæa, the Anaitis of the Greeks; and the statue of her at Cnidos, by Praxiteles, was regarded by antiquity as the masterpiece of that sculptor. The eastward extension of her worship under the Achæmenian kings of Persia is indicated by such names of places as, for instance, of the Afghan town of Bebi-Nani, *i.e.*, of "Our Lady Venus." We have a yet more interesting proof of the ancient prevalence of her worship in the West, in the Greek comedy of Νάννιον, by Eubulus [*circa* B.C. 37], so-called after its heroine, a courtesan—that is, in the original meaning of the word, a priestess of Nana. Nana, or Ishtar, was, in fact, the ubiquitous "Asiatic Goddess," the great "Dea Syria," "Dea Phrygia," "Pessinuntia," "Berecynthia," "Mater Dindymene," "Idæa Mater," and "Bona Dea," of the Greeks and Romans, called also Ops, and Rhea and Cybele†:—

"Renown'd for fruite of famous progenie,
Whose greatnes by the greatnes of none other,
But by herselfe her equall match could see."

She is also historically identified with the Aphrodite of Paphos and of Cnidos, and the Artemis of Ephesus; while in certain of her aspects she would seem to resemble Athene. Her name of Rhea is said to be the Assyrian word *ri*, for her sacred number, 15. Cybele, I believe, means simply "the Great" goddess [*cf. al Kabir*, "the Great," the thirty-seventh of the ninety-nine Muslim names of God]. The mysterious Cabeiri associated with her rites are, in my opinion, "the great gods" of the

* Anna Purna [literally, "Full of food"] is one of the names of the Hindu Earth-Mother Parvati [literally, the "Mountaineer"], as the provider of food.

† Compare Uzziel ["The Mighty One of God"], the Arch-angel, next in rank, in Semitic angelology, to Raphael.

* Not of the secular Ramjani, Kanchani, and Naikan classes. *Cf.* the *kedesah*, or "consecrated" and *zonah* of the ancient Semites, and ἱερόδουλος, and πόρνη of the Greeks.

† "Mater cultrix Cybele" [Æneid. iii. 111]; "Alma Cybele" [x. 220].

"Alma parens Idæa Deûm, cui Dindyma cordi,
Turrigeræque urbes, bijugique ad fræna leones."
[Æneid. x. 252-3.]

seven planetary spheres reduced to little talismanic figures [*cf.* *ναννιόν* and *nanus*], similar to those of the Dii Majorum Gentium and Dii Selecti, seen in any Hindu temple, set round the great image of the god or goddess to whom the temple is more particularly dedicated.

The most ancient representations of her are of a naked woman with a child in her arms, and it may be conjectured that the sublime vision in the Book of Revelation [ch. xii.] of the Woman clothed with the Sun and Moon, and crowned with the Twelve Stars—"the twelve [phallic] towers" [*cf.* *στοιχεῖα*, "uprights," "first principles"] of the Zodiac of the Arabs—was inspired by this conception of Ishtar as the divine harlot Mother of Nature. By the Phœnicians she was represented as a robed goddess, with four wings, and a conical, or a turreted, hat on her head, and generally with a dove, either held in her hand or perched on her shoulder. Sometimes she would appear, as in Arabia, to have been symbolised simply by the acacia tree, or rude phallic stones; and, judging from my own observation in India, I have no doubt that such were the forms under which she, and Il, and Asshur, and the rest of the pagan Semitic pantheon, were first worshipped in Mesopotamia, and in which the conventional Tree of Life [*asherah*] of Chaldæo-Babylonian and Assyro-Phœnician religion and art originated.

(*To be continued.*)

HOME INDUSTRIES.

Frozen Meat and British Handling.—Mr. W. D. Lysnar, Mayor of Gisborne, New Zealand, and chairman of the Gisborne branch of the New Zealand Farmers' Union, has just published a report on the New Zealand frozen meat trade with this country, which indicates great dissatisfaction amongst shippers, and is of considerable interest to consumers in this country. According to Mr. Lysnar, the handling and disposal of the meat in London are very unsatisfactory. The meat is not handled either with despatch or in a way to protect it from as much injury as possible. The average damage to all New Zealand meat imported into London Mr. Lysnar puts at from 10 to 12 per cent., and in his opinion this damage arises in London. He says that the system of sorting the produce in the hold of the ship instead of in a goods shed is wrong; that the system of discharging the ship with hatches only partly covered from the weather is wrong; that the method of handling the meat in running it down shoots and landing into barges and trucks is unsatisfactory; that most of the barges that are used to convey the meat from the ship up the Thames, to the various delivering points, are in an unfit state for the purpose; and that the method of carting the meat from the barge or store on the river bank to the Smithfield Market and to the railway stations for general distribution is very unsatisfactory and expensive. Mr. Lysnar says the meat could be handled in a much more satisfactory way in Bristol, Liverpool, or Manchester, where provision is made to deal with the produce in a very expeditious and cheap way. If the produce was sent to Liverpool, Mr. Lysnar states that it could be delivered at Birmingham at 40*s.* per ton, as compared with 53*s.* 9*d.* per ton from London, and with less damage.

The Cycle Trade.—Many causes have combined to make 1910 a bad year for the cycle trade. The bad weather, more especially in the early part of the year, when the foundation of the year's trade is laid, the dearness of rubber and the consequent advance in the price of tyres, the decline of cycling in the largest centres owing to the motor traffic, the strikes and lock-out in the North of England which prevented the working-men, who are the chief buyers of the ordinary bicycle, from buying in large numbers; all these causes have tended to depression in the trade. Given good weather, the expectation is that 1911 will show great improvement, more especially in the motor-cycle trade. A trustworthy engine, fitted to a light-weight machine, is now an accomplished fact. Even this year the motor-cycle trade has been good, and one company is said to have sold its output for several months ahead. The cycle export trade in 1910 has shown better results than the home trade. In the eleven months ended November 30th the number of cycles shipped from the United Kingdom was 120,450, of the total value of £504,994, against 98,405 and £433,191 respectively in 1909, and 91,590 and £430,692 in 1905. The export trade in motor-cycles also showed substantial growth. In the eleven months ended November 30th the number sent abroad was 2,936, of a value of £108,655, as against 1,576, valued at £57,764 in the corresponding period of 1909. The cycle import figures are not less satisfactory, showing, as they do, decreases. Taking the same period, to the end of November, the number imported was 418, of the value of £2,944, as against 499, valued at £3,573, in the corresponding period of 1909. The import of motor-bicycles has been somewhat less satisfactory, being 1,340, of the value of £42,756, as against 1,353, valued at £38,250, in 1909. The hire-purchase system seems to have gone out of favour, but it is still extensive.

Motor-Engines for Warships.—It is rumoured again that three large motor-engines are being built for a British "Dreadnought" of this and next year's programme, but confirmation is wanting. All that is certain is that the Admiralty have been enquiring of British makers of internal combustion-engines whether they would undertake the construction of engines much larger than any they have yet put upon the market.

Railway Companies and Plant.—For many years there has been sharp controversy as to the wisdom of railway companies building their own locomotives. It has been urged with much force that they would be better advised to go outside. A railway, it is argued, must work under serious disadvantages. When its demand is small, much of its plant must be idle, since it cannot take orders from outside to keep it occupied; when its requirements increase it may find its resources inadequate, and have to ask outside makers to help them—assistance which, in the circumstances, must be costly. Then a railway, secure from competition, has no incentive to conduct its works on strictly commercial lines, and the transference of orders to large independent companies would tend to do away with the heterogeneity of detail which is so noticeable in the engines of different companies. But the interests which favour the present system are powerful, and not easily overcome. It may, however, be that the tests which several of the leading railway companies have lately united to carry out with each other's engines may be the forerunner of the abandonment of the present system, and lead either to the establishment of joint works for the construction of locomotives, or the employment of outside companies. In the latter case, the railway companies would shut down their works for building purposes and concentrate the energies of these establishments on repair and research work. The alternative policy would be for the railway companies to establish, under railway ownership, large works in which all locomotives for the companies interested would be built to standard design. The probable result in either case would be substantial economies in the locomotive departments of the companies concerned.

Wool Supplies.—The consumption of wool during the present year has beaten the record, and it is unlikely that 1911 will exceed it. At the end of October the exports from Australia showed an increase, as compared with those of the first four months of 1909, of 72,000 bales. In November 1909 the shipments from the Commonwealth reached the immense total of 382,000 bales, but for the same month of the present year they amounted to 421,000 bales. Up to the end of November, or for the first five months of the present wool year, the exports of wool from Australia show an increase of 116,000 bales. The New Zealand exports, which showed a decrease at the end of October of 4,000 bales, at the end of November were 17,000 bales in excess of the exports for the corresponding five months of 1909. As was to be expected, the market for merino tops at Bradford is gradually declining, in consequence of these heavy shipments.

The Cotton Crop.—Notwithstanding more sanguine estimates and the ginning reports, Messrs. Neill Brothers hold to their estimate of 11,600,000 bales. They account for the heavy receipts by the desire of planters to sell at high prices and the strong trade demand. They assume, too, that 90 per cent. of the crop was ginned up to December 1st, against 88 per cent. last year. As to the Bureau Estimate, Messrs. Neill interpret the 11,426,000 bales as 11,314,000, because the Government's calculation weight is too small, and then, adding linters, they bring the total to 11,614,000 bales, which differs only very slightly from their own estimate. Meantime the International Association of Tropical Agriculture has published an address on cotton cultivation delivered by Professor Dunstan to the congress held at Brussels in May. It is a little belated, but it may be noted that in his opinion, if the best results in the production and improvement of cotton are to be got, Government departments are necessary. Professor Dunstan quotes the opinion given in a report issued by the United States Department that only a third of the available area within the cotton belt of the United States is cultivated, and great increases in the production on the present acreage may be expected from intensive cultivation. There are now being conducted, in twenty parts of the world, more or less scientific attempts to increase the cotton supply, but it must be many years before they have much effect on the large questions of supply and demand. It seems probable that cotton prices will continue to be high for some time to come.

Shipbuilding and the National Shipbuilders' Agreement.—The standing committee of the associated trade unions has been in conference with the executive of the Employers' Federation, with the Boilermakers' Society, and with the Board of Trade, with the result that assurances have been given that the observation of the national agreement shall be mutual. And so, after many weeks of enforced idleness, which have exhausted the funds of the Society, caused the men much misery, and the masters great loss, the dispute is settled, and an undertaking which ought to have been given when the York agreement was formulated has restored the shipyards concerned to their normal condition. During the stoppage of work the demand for new ships has increased, and next year promises to be a good one for the shipbuilding industry, always assuming that fresh labour troubles are avoided. And with the shipyards busy again, every branch of the iron trade will be more active. The production of steel was reduced during the lock-out by from 40 to 50 per cent. in the majority of the works, but the loss should now be quickly made up.

Murder and House Property.—It is curious how a murder of the sensational kind injures house property in the neighbourhood in which it was committed. The district in which Peace the Penge murderer lived suffered severely in this way, and now residents in Hilldrop-crescent, Islington, the place of the Crippen murder, have applied to the London County Council to have the name changed. Many of the houses are said to be now empty, and all the property has depreciated in value. The Council have asked the opinion of the Islington Borough Council, but their works committee say that they have no direct evidence as to

the views of the owners and occupiers of the houses in the Crescent, and without that they recommend that the name shall remain as it is. An instance of the name of a place being changed owing to its association with a murder is the case of the Euston-square mystery in the 'seventies. A petition resulted in the south side of Euston-square becoming Endsleigh-gardens.

CORRESPONDENCE.

YERBA (OR MATÉ) TEA.

Yerba Maté, the dried and pounded leaves and small twigs of *Ilex Paraguayensis*, has been mentioned once or twice recently in the Society's *Journal*, I notice. Jesuit tea is a most refreshing beverage, and I have very pleasant recollections of it some years ago in the Argentine. It was usually infused in a small gourd, and sipped through a silver bombilla while scalding hot. Each person present took a sip and passed it on. Personally, I always preferred to take it, when possible, as a tea without milk. In case you may wish to make a trial of it yourself, I am sending you a small packet of some I brought from Rosario in 1886.

If by chance you are aware of how it may be obtained in London I should be glad if you would let me know.

As Mr. John Ryle has pointed out, it contains very little tannin, and may be of use to dyspeptics, but my impression is that its greatest value might be as a heart stimulant, if taken periodically. After drinking it habitually several times a day over a lengthened period, one has some difficulty in doing without it, for, as I have said, it is a mild cardiac stimulant, and the effects of leaving it off suddenly may result in somewhat serious prostration, as I well know from personal experience. It is probably on account of its action on the heart that the natives only sip it instead of drinking it in quantities as I did. It has been stated that the mortality from heart diseases is greater in the Argentine than elsewhere, and the reason has been ascribed to maté drinking, whether rightly or wrongly I cannot say. CUTHBERT CHRISTY.

OBITUARY.

FREDERIC JOHN VAVASOUR GUY.—News has just been received of the accidental death by gunshot of Mr. Frederic John Vavasour Guy, of Kuala Lumpur, Federated Malay States. Mr. Guy served throughout the South African War with Van Allen's Field Hospital, and afterwards became manager of the Federal Dispensary, Kuala Lumpur, Selangor. In December, 1908, Mr. Guy joined a scientific expedition into the unexplored wilds of Perak. The expedition returned with a number of new botanical specimens, after undergoing great hardships. He was an enthusiastic hunter of big game; at his residence at Kuala Lumpur there is a fine collection of wild animals, birds, and reptiles —probably the finest in the Malay States. He joined the Royal Society of Arts in 1909.

NOTES ON BOOKS.

BRITISH WEIGHTS AND MEASURES. By Colonel Sir C. M. Watson, K.C.M.G., C.B. London: John Murray. 2*s*. 6*d*. net.

In 1906 Sir Charles Watson read a paper before the Society on the metric system, in which he set out the objections to its compulsory introduction into this country. The present book may be taken as a continuation of this paper, though in it the author does not express any opinion as to the merits or demerits of the proposed change. He contents himself by setting out in a popular and intelligible form the history of the origin of our present measures. He traces them all to the laws of the Anglo-Saxon kings, although, as he says, the investigation might be carried a long way further back until the origin of the measures and weights we are using to-day is to be found in the ancient measures of the East and of the Roman Empire. As a matter of fact, the principal denominations have been changed very little, or not at all, for the past thousand years, and it may reasonably be inferred that measures which have thus stood the test of time and practice are at all events fairly well suited for practical use. This is not to say that during this long period they have not developed in various directions, and consequently have become more complicated, though much of the complication has been removed by recent enactments, which have put an end to many of the various weights and measures used in different industries and for different purposes.

In practice most of the old gallons, pounds, ounces, and cubits have disappeared, and it is only here and there that the use of the ancient measures or weights has been continued. The multitudinous variations of the old denominations have often been enumerated, and their use or their existence employed as an argument in favour of the more uniform metric system. No doubt some still remain. One instance may be given, which is not mentioned by Sir Charles Watson. He names six different gallons, of which only one, the imperial gallon of 1824, is said still to survive. As a matter of fact the old barn gallon of sixteen pints is still in common use, at all events for the wholesale purchase of milk, and it may be assumed that there is a certain convenience in this, or it would not have been kept alive.

However, the relative advantages of the old British system with its complications, and of the new metric system with its admitted inconveniences, have often been discussed, and the discussion is still being waged as vigorously as ever. One conclusion at all events may be admitted, and that is that it seems very much easier to change the coinage of a people than it is to alter its weights and measures.

Journal of the Royal Society of Arts.

No. 3,032. VOL. LIX.

FRIDAY, DECEMBER 30, 1910.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 4th, 5 p.m. (Juvenile Lecture.) ARTHUR MASON WORTHINGTON, C.B., M.A., F.R.S., Professor of Physics in the Royal Naval College, Devonport, "A Study of Splashes, conducted by the aid of Instantaneous Photography." (Lecture I.)

Most of the tickets have now been issued, but some still remain, which will be supplied to Members who apply for them at once.

Further particulars of the Society's meetings will be found at the end of this number.

EXAMINATIONS, 1911.

The Examinations will be held from April 3rd to 7th inclusive.

The last day for receiving applications will be February 28th.

The following are the subjects:—Book-keeping, Accounting and Banking, Shorthand, Type-writing, Economics, Précis-writing, Commercial Law, Commercial History and Geography, Arithmetic, Business Training, and Modern Languages.

The Examinations will be held at any place in the United Kingdom where an Examination Committee is willing to undertake the necessary arrangements. Applications for new centres should be submitted for approval at once.

The Examination Programme for 1911 containing the regulations for the formation of new centres, syllabuses of all subjects and the papers set in 1910 may be obtained from the Secretary of the Royal Society of Arts, John-street, Adelphi, London, W.C. (price 3d., post-free 4½d.).

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

INDUSTRIAL PYROMETRY.

By CHARLES R. DARLING, A.R.C.Sc.I., F.I.C.

Lecture II.—Delivered November 28th, 1910.

THERMO-ELECTRIC PYROMETERS.

It might be supposed, at first sight, that the electromotive force developed by a heated junction of two metals, increasing with the temperature, could readily be applied to the construction of a pyrometer. Yet it was not until more than sixty years after Seebeck discovered the phenomenon that a satisfactory instrument was introduced, for reasons which will now be considered. Firstly, it is essential that the metals used must possess melting points higher than the temperature to be measured; and hence, if it be desired to measure 1,200° C. or more, the only metals left to choose from are iron, nickel, palladium, metals of the platinum series, and the more recently-produced metals, tantalum and tungsten. Nor does it necessarily follow that any pair of these metals, taken at random, would give a satisfactory result, as instances occur in which the electromotive force generated first of all increases as the temperature rises up to a certain point, after which it diminishes, and, on raising the temperature still further, an electromotive force in the opposite direction is established. This occurrence is known as "thermo-electric inversion," and is shown by several pairs of metals. I take, as an illustration, a junction of iron and copper, and couple the free ends to the galvanometer. On heating in the burner, the spot of light moves to the right for a time, but, as the temperature of the junction rises, the spot is observed to return, and finally to pass the zero mark and travel to the left. If we attempt to obtain a clue to the temperature of the junction by observing the position of

the spot of light, we are confronted with the dilemma that each mark on the right of the scale will correspond to two temperatures, and the attempt would therefore be futile. Evidently, a suitable junction must not be liable to the inversion effect at any part of the range over which it is used, and the electromotive force produced must continuously increase as the temperature rises. This requisite still further restricts the range of selection; but beyond this it is necessary that the metals used must be capable of remaining at a high temperature for an indefinite period without undergoing oxidation or corrosion, or being liable to any change of internal structure that might produce an alteration in the thermo-electric value of the junction. It is no cause for wonder, therefore, that under such exacting conditions the production of a successful thermo-electric pyrometer was so long delayed.

The problem was finally solved by Le Chatelier, who introduced, in 1886, a pyrometer in which the junction was formed of platinum as one metal, and an alloy of 90 per cent. of platinum and 10 per cent. of rhodium as the other. This was used in conjunction with a d'Arsonval galvanometer, from the scale of which temperatures were read, and was found to be reliable and satisfactory. It would be difficult to estimate the benefits which have accrued from this epoch-making discovery, which at once enabled researches at high temperatures to be conducted with accuracy and ease, resulting in improved methods and economy in working. Shortly afterwards, Barus in America, and Roberts-Austen in this country, showed that the rhodium-platinum alloy might be replaced by an alloy of platinum and iridium, containing 10 per cent. of the latter metal, with equally successful results. The cost of these metals is an unfortunate drawback, but no cheap substitutes of a satisfactory character have yet been discovered.

Before proceeding to examine the practical forms of instruments in daily use, it will be of advantage to consider briefly the laws governing thermo-electric phenomena in relation to pyrometry. An ideal thermo-electric circuit consists of two junctions, A and B. One of the metals connects A to B, whilst the other metal is made in two pieces, the free ends of which are joined to the galvanometer. The law that governs this circuit is that the electromotive force generated is proportional to the difference in temperature between the two junctions A and B. We can demonstrate this law experimentally by the aid of a circuit, which I now couple up to the galvanometer. No deflection is shown, as there is no difference between the temperatures of the two junctions; but on placing a burner beneath one of them a current is immediately established in the circuit and the spot of light moves. But if now I transfer the flame to the other junction, we notice that the deflection falls off, and when the temperature of the second junction exceeds that of the first a deflection in the contrary direction is established. Finally, I place a burner beneath each junction, and when both attain an equal temperature no deflection of any kind is noted. This is owing to the arrangement of the circuit being such that the currents generated at each junction flow in opposite directions, and thus neutralise each other.

It would be a great advantage if this ideal arrangement could be carried out in practice, but the high price of platinum and similar metals acts as a serious deterrent to such procedure. If we imagine A to be the junction placed in the furnace, and B to be located outside in a cool place, the two junctions might suitably be joined together by the rhodium-platinum alloy. The free ends of the circuit would then consist of platinum wires, which would have to be carried to the galvanometer, which might be many yards distant, and ought, in an ideal arrangement, to possess platinised terminals. The high cost of such a procedure renders a compromise of some kind necessary, and the plan usually adopted is shown in the diagram. The junction to be placed in the furnace is made by fastening together two fairly stout wires, one of platinum, and the other of rhodium alloy, and is located at one end of a protecting sheath, and the wires are brought from the junction through twin-bore fireclay, which serves to insulate them, to brass terminals at the other end of the sheath. Copper wires lead from these terminals to the galvanometer, and hence at this end of the pyrometer there exist several junctions of dissimilar metals, viz., platinum and brass, rhodium-platinum and brass, and two junctions of copper to brass. But if all these junctions be kept at a constant temperature, identical with that existing when the pyrometer was standardised for temperatures, no error will arise; and in order to realise this condition in practice the cold end or head of the pyrometer is shielded by a covering made of some material which acts as a non-conductor of heat, such as wood or fibre, and the instrument

standardised at the temperature attained by the head when in use. These points of construction may be noted in the instruments on the lecture-table; in one, the head is contained in a wooden cover; in another fibre is used; whilst in a third (Fig. 5) errors due to alterations in the temperature of the junctions in the head of the pyrometer are prevented by passing a continuous stream of water through the containing chamber.

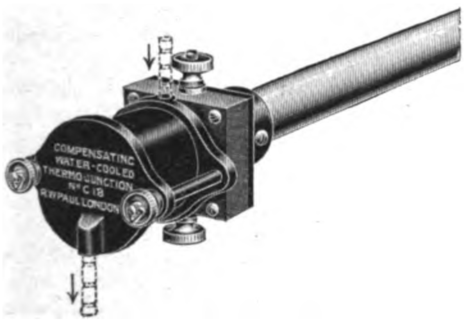

FIG. 5.—PYROMETER WITH WATER-COOLED HEAD.

It will thus be observed that the construction of a thermo-electric pyrometer is simple, and calls for no further mention except with regard to a few practical details. The "hot" junction is made by sealing the two wires together in a blowpipe fed with oxygen, and a spare quantity of each wire is usually contained in the head which may be drawn down the perforated fireclay tube to form a new junction when necessary. The protecting sheath, which prevents the wires from coming into contact with the gases or materials of the furnace, and thereby obviates corrosion, may be made of mild steel for temperatures up to 1,000° C. or 1,800° F. Beyond this temperature a better fire-resisting material, such as fused silica or fireclay, must be used, with the unavoidable disadvantages of fragility and slow transmission of heat from the furnace to the junction. The total length of the pyrometer is decided by the distance of the portion of the furnace at which a measurement is required from the exterior, remembering that the temperature recorded is that of the part surrounding the hot junction, and also that the head of the pyrometer should be kept at least one foot away from the exterior of the furnace.

The galvanometer first used by Le Chatelier was of the moving-coil pattern, with a mirror attached to the upper suspension strip, from which a spot of light may be reflected on to a scale. Most people who have been accustomed to work with mirror galvanometers would probably form the erroneous conclusion that these instruments could not be applied successfully in a factory owing to the vibrations caused by machinery or hammering. In the Royal Gun Factory at Woolwich, however—a department which has always been at the forefront in pyrometric work—mirror galvanometers are exclusively employed. These are of the Holden-

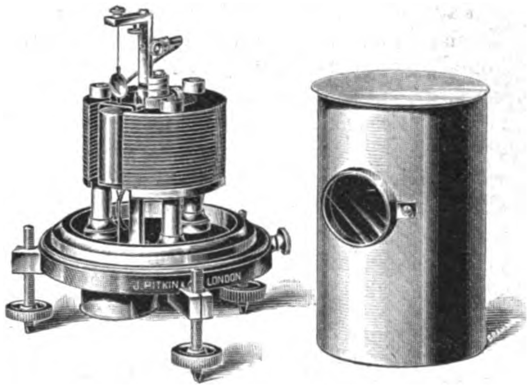

FIG. 6.—HOLDEN-D'ARSONVAL GALVANOMETER.

d'Arsonval pattern (Fig. 6), and are hung from a ring, which rests on three supports, by means of springs. One of these galvanometers I am using for experimental work in these lectures, and you will observe that we can shake it about and subject it to a considerable amount of rough usage without detriment. The advantage possessed by the mirror galvanometers over instruments provided with a pointer is that a longer scale, and therefore a more accurate reading, is possible. Most users, however, prefer an indicator in which a reading may be taken by noting the position of a pointer attached to the moving part of the galvanometer; and the progress made in the manufacture of electrical instruments has resulted in the production of many accurate indicators of this type. All these are millivoltmeters of the moving-coil type, which have the advantage of an evenly-divided scale. Amongst British makers may be mentioned the Cambridge Scientific Instrument Company, Messrs. Crompton and Co., Messrs. Siemens, Pitkin and Co., and R. W. Paul, all of whom are represented in the instruments on the table. The present practical limitations of these indicators do not permit of a greater movement of the end of the pointer than about six inches; which means that in a range of 1,200° a space of one inch represents 200°, and a closer reading

than 10° becomes difficult. With a mirror galvanometer, and a scale three feet distant from it, the spot of light may be made to traverse twenty-four inches or more, and thus to give a far more sensitive indication.

We shall now enter into the question of the marking of the scale of the indicator, so that standard temperatures may be read off directly. Let us suppose that the highest temperature to be read is 1,100° C., and that we start with a blank scale, and with the head of the pyrometer kept at the temperature it will attain in practice. We may now place the end of the pyrometer in boiling water, and when the reading is steady mark the position of the pointer 100° C. or 212° F. From the table of fixed points, to which reference was made in the first lecture, we can select several substances such as lead, antimony, common salt, and copper, and having melted the substance in a crucible, we insert the pyrometer and watch the pointer. As the molten mass cools, the pointer moves slowly towards its zero, but when solidification commences, this movement ceases, owing to latent heat being disengaged during the change of state, which balances the loss by radiation and prevents the temperature from falling until solidification is complete. I show this experimentally by dipping a thermal junction into melted wax in a glass tube, which I now immerse in water. You observe the deflection of the spot of light to decrease; then, whilst solidification is in progress, it remains steady, and finally falls again towards zero. The steady position of the pointer on the scale is marked with the number given as the melting point of the substance used; thus lead is 327° C. or 620° F.; antimony, 632° C. or 1,169° F.; common salt, 800° C. or 1,472° F.; and copper, covered with graphite, 1,082° C. or 1,980° F. We shall find, on a good indicator, that equal temperature intervals are practically equidistant on the scale, which may, therefore, be evenly divided up between the points, and the markings continued to the limit of 1,100° C. This is shown in the slide, which represents a calibration curve in which deflections are plotted against temperatures, and it will be seen that up to 1,100° C. the curve is nearly a straight line.

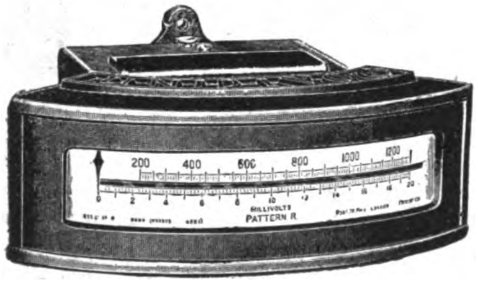

FIG. 7.
INDICATOR FOR THERMO-ELECTRIC PYROMETER.

An alternative method of marking the scale is to note the microvolts corresponding to the deflection, and to calculate the temperature from Le Chatelier's formula:—

$$\log E = A \log t + B$$

where E = electromotive force in microvolts; t = temperature; and A and B = constants depending on the materials used, and which must be determined beforehand. The former method is simpler in practice.

We may now enquire into the capabilities and industrial uses of a pyrometer made and calibrated in this manner. It is found that continued use at temperatures exceeding 1,200° C. or 2,200° F. causes an alteration in the thermoelectric properties of the hot junction, whereby the temperatures indicated are incorrect; but below this limit little alteration is noted. With a sufficiently large scale, and due attention to ensure that the head of the pyrometer is at the correct temperature, readings to within 5° C. or 9° F. may be obtained. As it is hardly possible to control a large furnace to a finer degree than this figure, the pyrometer fulfils all the conditions imposed by large-scale operations. The indications are automatic, and may be read with as little trouble as the time on a clock. It may therefore be used for all furnaces in which the temperature does not exceed 1,200° C., such as annealing furnaces for steel and other metals; in regulating temperatures for the hardening of steel; in retorts used for the manufacture of coal-gas; in lime-kilns; and in pottery kilns when the working temperature does not exceed 1,200° C. It is a common experience amongst manufacturers that owing to the absence of failures the initial cost of one of these pyrometers is saved in a few months; and we may therefore confidently look forward to a continued extension of their use.

Now it frequently happens that a knowledge of the rate at which the temperature of a furnace rises is quite as important as the actual reading, and it would be a manifest advantage if a continuous record of the temperature of the furnace over a given period could be secured. The first instrument for thus recording temperatures was designed by Colonel Holden, F.R.S., in conjunction with the late Sir W. Roberts-Austen, and was intended for use with a mirror

galvanometer. As made at the present time, it consists of a light-tight box, at one end of which the galvanometer is placed. Light from the exterior is reflected by a right-angled prism on to the mirror of the galvanometer, whence it is reflected on to a piece of sensitised paper wound round a cylinder which is made to rotate at a known speed by internal clockwork. If the mirror remain stationary—representing a steady temperature at the end of the pyrometer—a straight mark will be traced on the sensitised paper as it rotates, whilst fluctuations in temperature will cause the mirror to move to the right or left, thus producing a wavy line on the paper. By trials at known temperatures, the paper may be divided by lines representing say 10° C. between each pair, each line being marked according to the actual temperature it represents. The paper, after use, may be removed and fixed, and forms a permanent record of the operation which often proves valuable for future reference. Although this photographic process entails more labour than a recorder which, like others to be described subsequently, trace a line in ink, it possesses the superiority of delicacy of reading derived from the use of a mirror galvanometer.

The Siemens-Halske recorder is applied to a galvanometer which carries a pointer attached to the suspension. At the end of the pointer is attached a small stylus, and at stated intervals, regulated by clockwork, a bar descends and presses the stylus on to a sheet of paper, beneath which is placed an inked ribbon, thus forming a dot on the paper. The bar then rises, and remains free of the pointer for a sufficient time to allow the galvanometer coil to swing into the position which represents the temperature of the pyrometer, after which the bar again descends and makes a second dot. The paper is fed forward at a definite rate by clockwork, and is divided horizontally into temperatures. The record obtained is permanent, and consists of a nearly continuous curve formed by successive dots. The same principle is applied in the "Thread" recorder, made by the Cambridge Scientific Instrument Company, the action of which will be understood from the diagram, which shows the pointer attached to the galvanometer suspension and the bar which descends under the action of a cam. In this case, however, a V-shaped piece at the end of the pointer presses upon an inked thread, which is made to touch a graduated paper wound round a drum, rotated by internal clockwork. These instruments possess the advantage of giving a visible record. [Examples of the recorders described were exhibited in the room.]

There is one advantage possessed by thermo-electric pyrometers which I desire to mention before passing to the description of other types. Provided that the wires forming the junctions are identical in thermo-electric properties, any number of pyrometers can be attached, through a suitable switchboard, to a single indicator. This is shown in the slide, in which H^1 and H^2 are the hot junctions of two pyrometers. When the arm of the switch is moved to one position, the temperature of H^1 may be read; when on the second position, that of the hot junction H^2 is indicated, and so on indefinitely. The galvanometer may be located in the foreman's office, and he is thus enabled to ascertain the condition of all the furnaces under his charge without leaving the office. All the numerous furnaces in the Royal Gun Factory, Woolwich Arsenal, are thus controlled by means of a carefully-standardised indicator; and the economies effected in fuel, and in the prevention of failures in the hardening and other processes, amount to a sum representing many times over the cost of the pyrometric installation.

Fig. 8.—Cheap-metal Pyrometer with Cold Junction in Head.

Time will not permit of a description of the many ingenious details which in late years have been devised with a view to eliminating the possible errors which might arise in the practical working of these pyrometers. Even in a general survey of the subject, however, it is not possible to omit a reference to the results obtained with thermal junctions composed of the cheaper metals. For temperatures not exceeding 700° C. (1,290° F.), a junction of copper and constantan gives excellent results, and costs little to renew. Up to 900° C. (1,650° F.) copper and nickel or iron and nickel are satisfactory; the latter metals being employed in Crompton's pyrometer. The Foster Company now make an iron-constantan pyrometer to read to more than 1000° C., which costs little to renew if destroyed by continuous oxidation. When any of these junctions are

used, the head of the pyrometer may be abolished, and the wires led directly to the vicinity of the indicator, where a cold junction, not liable to fluctuations, may be formed as represented in our ideal circuit. Moreover, the electromotive force developed by these junctions, for a given rise in temperature, is five times as great as that yielded by a couple formed of platinum and rhodium-platinum; and this enables an indicator of the spring-controlled type to be used instead of a suspended-coil instrument. The former is stronger and cheaper, and the total cost of an outfit for reading temperatures up to 900° C. is in consequence comparatively trifling.

Instances in which processes have been improved, money saved, and failures averted by the use of thermo-electric pyrometers might be multiplied indefinitely. And thus the discovery of Seebeck, regarded at the time it was made merely as a scientific curiosity, has led to results of the highest importance in modern industry.

[The following instruments were exhibited :—

1. Pyrometers with ordinary and water-cooled heads by Messrs. Siemens Bros. and Co., Ltd., and R. W. Paul.

2. Indicators of various patterns by the Cambridge Scientific Instrument Company; Messrs. J. Pitkin and Co., R. W. Paul, Crompton and Co., Siemens and Co., and the Foster Instrument Company.

3. Cheap-metal pyrometers by Messrs. Crompton and Co., and the Foster Instrument Company.

4. Thermo-electric recorders by Messrs. Siemens and Co., the Cambridge Scientific Instrument Company, and J. Pitkin and Co.

5. A multi-junction pyrometer by Messrs. A. Gallenkamp and Co.]

THE CHRISTMAS TREE.

By Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.

Part II.

Among all races religion,* as the sense of Divinity in Nature, exhibits itself at first in those degraded forms of polytheism that are generically described by ethnologists under the term of animism, or the worship of the telluric powers of the upper [terrestrial] and lower [chthonian] earth; and it never rises above this low type of worship among races permanently arrested in their mental growth; although animism seems to possess in itself the power of indefinite development, being, indeed, the source of every known system of religion, whether polytheistical or monotheistical. Also within the proper limits of its arbitrary definition it assumes many shapes, such as fetichism, atavism, and phallicism. Fetichism is the worship by incantations, enchantments, and fairie (*fari*, to speak; *fatum*, the word spoken, fate), that is, by the intoning of magical formulæ, of any natural or artificial objects, under the conviction that the spirits imagined to inhabit them, or rather to be identified with them, can thereby be compelled to comply with the wishes of the worshipper. It is, strictly speaking, a system of sacramental conjuring, such as still flourishes among the Negroes, and the Mongols or Black Tartars, of North-Eastern Asia; and was the primitive religion of Chaldæa. Atavism is the worship of ancestors, as illustrated by the worship of patriarchs, founders, and heroes (Euhemerism) by the Greeks; of the domestic Lar by the Romans; of the *pitris* and *prajapatis* [Penates, Patriique dii] of the Hindus; of the *teraphim* by the Hebrews [Gen. xxxi. 19, 30, 32, 34, and elsewhere throughout the Old Testament]; and of *totems*, or representative family animals, by the Red Indians. At first atavism was, as it still remains among the Red Indians, a debased magical system of divination by means of visionary communion with the dead, or necromancy* specifically; but among the Aryas it gradually passed into a comparatively pure service rendered to graven and molten images, or idolatry proper; while among the Semites it became insensibly sublimed into the most uncompromising spiritual monotheism. The very name applied to the Diety by the Hebrews to distinguish Him, as the term *elohim*† [gods] could not, as the one true God,—a name they never, within their historical memory, applied to any false god, although during the period of their earlier kings they used it henotheistically,‡ and

* That is, religion in the sense of "relegens," fearing, reverencing, the gods; rather than of "religans," binding by creeds, rites, dogmas, customs, morals, etc.

* From the corrupt spelling of which word [compounded of *νεκρός*, a corpse, and *μαντεία*, prophetic power], as negromantia, we get, by translation, the phrase, "black art."

† Where in the English Authorised Version of the Bible the word God is used, the original Hebrew has *elohim*, "gods." This false translation, which is followed in the Revised Version, is excused on the pretence of *elohim* being the "plural of majesty"; an explanation utterly untenable, at least in all the earlier Biblical instances of the use of the word.

‡ A word, I believe, first used in Max Müller's "Hibber Lecture,' compounded of *ἑνός* (genitive of *εἷς*), one, and *Θεός*, God, and signifying the worship of one god for oneself,

not absolutely monotheistically, and, after the Captivity, held so sacred that they never pronounced it, always substituting for it, when reading their Sacred Scriptures, the word *Adonai*, "The Lord,"—this "separating name," this terrible name of "Jehovah," would now appear to have been transmitted to them from that of the family *teraph*, or *totem*, of the tribe of Joseph, and the house of Moses. In many of the armorial bearings and charges of noble European families we have, on the other hand, examples of the survival of *totems* as mere heraldic marks. Phallicism, which grew up inevitably from fetichism and atavism, and is in many of its aspects, identical with atavism, is the worship of the vital, active and passive procreative principles of Nature; under figures furnished by the rudest stones, by mountains and valleys, by trees, by serpents, by the sun, and by the poetical figment, common to all the Caucasian races, of the Tree of Life.

Among the Caucasian races, the low animist worship of the visible world was raised to the higher worship of Nature, in the two principal forms of (1) sabaism [from *saba*, "an host"—of heaven], or the worship of the seven planets, the twelve signs of the Zodiac, and the host of heaven generally, originating with the study of astronomy among the Hamites and Semites of Chaldæa, the special stronghold in ancient times, as China is in modern, of sabaism; and (2) polytheism, or the worship of personifications of the phenomena of Nature, that is, of "many gods." The latter worship is specifically idolatry, or the sacramental dramatisation of Nature, and it is the intuitive religion of the Aryan races. In the hymns of the Vedas, we see this polytheism passing from its simpler forms of direct worship of phenomena, to the deification of the very adjectives [on the principle of "nomen numen"] qualifying them. In the perfected polytheism of the Greeks, these deities, invested with all the thoughts, passions, and actions of human beings, are almost completely dissevered from the phenomena they impersonate, and by the virtue of the immortal beauty wherein they live and move, and have their being in the poetry of Homer, and in the sculpture of Phidias and Praxiteles, they will remain divine for evermore.

Monotheism, the final and most elevated expression of natural religious feeling, is the worship of a universally postulated Supreme Being:—

"Father of All! in every age,
In every clime, adored,
By saint, by savage, and by sage,
Jehovah, Jove, or Lord."

The minds of individual men of exceptional powers of generalisation must, indeed, from the beginning, have been lighted up, as by a supernatural illumination, with some glimmering of the unity of the godhead. Polytheism, with its hierarchies of "gods many and lords many," of itself suggests the idea of some one superior god, to whom the rest are subordinate; and, particularly, when characterised by the predominating worship of a Sun-god into whom, in every polytheistical system, all the other gods at last become resolved, after the manner of the resolution of every female deity into one all-absorbing Earth-Mother. We are thus enabled largely to explain the inextricable mixture of monotheistic doctrines with even the most rudimentary forms of polytheism; and, in fact, the majority of polytheistical divinities are found to be co-extensive in their mythology with the entire range of the religious conceptions of mankind, being at once mere fetich stocks and stones, and astral, and phenomenal impersonations, or idols, and more or less pure and beautiful symbols of the eternally self-existing First Cause of all things. From this point of view, indeed, polytheism might well be regarded as a practical application of monotheism, if not a degradation from it; and as justifying, in some measure, the orthodox theological dogma of an original revelation of monotheism to mankind in the generations of Seth [Genesis iv. 26]. But modern ethnography has almost conclusively demonstrated that the human race, regarded collectively, has in reality been led very gradually through animism, sabaism, and polytheism up to monotheism. Judaism does not afford any exception to this law of Nature, for it was only through the most painful experiences, and by very slow degrees, that the Hebrews arrived at the conception of the spiritual nature of the godhead, and as a nation they do not appear to have completely attained to it until after "the Captivity." The existence of atavism among them, in the patriarchal age of their history, has already been alluded to; and, with other forms of animism, it continued to subsist, and indeed prevail, in both Judah and Israel to the seventh and eighth centuries B.C. When Jacob took the stone on

without denying the validity of the god or gods worshipped by other nations. And it is clear that for a long time the Jews regarded *Jahveh* simply as the God of Israel, in contradistinction to Moloch the abomination of the Ammonites, and Ashtoreth, the goddess of the Sidonians, and Chemosh, the obscene dread of Moab.

which he slept on his way from Beersheba to Haran, and set it up on end for a pillar, and poured oil on the top of it, and called it Beth-el, "the house of God," he performed a distinct act of phallic worship, such as may still be witnessed every day, at every turn, in India; although in his case it may possibly have already been merging into the worship of the one true God. Seven hundred years later we find that Absalom, not having "a son to keep his name in remembrance," "reared up for himself a pillar which is in the King's dale" [*Shah-veh*], and called the pillar after his own name; just as to this day, in India, a wealthy Hindu, if certain of being sonless, will set up and endow a *lingam* named after himself, or his father, in perpetual witness of the family stock [*stirps*] and kin [*gens*]. Even Moses, the reputed author of the Decalogue, when the Israelites were plagued with fiery flying serpents in the wilderness, made a serpent of brass and put it upon a pole. It was a solar-phallic emblem, set upon a Priapian pole, a combination of symbols constantly occurring in the serpent-worship of India. Sometimes it is the image of the disc of the sun, featured after the face of man, that surmounts the supporting staff; and it was probably in such rude phallic posts and props [*cf.* ἕρμα, κίων, στοιχεῖον] that statuary everywhere originated. The "Serpent of Moses" was an object of worship at Jerusalem down to the eighth century B.C., when it was destroyed by King Hezekiah, who derided it under the nickname of Nehustan, that is "Brummagen." The Old Testament also bears witness to the enduring vitality of phallicism among the Hebrews in its frequent references to "high places," "groves" [*asherah*, pl. *asherim*, or conventional images of the Chaldæan Tree of Life], "oracles," and votive "pillars"; and, so late as the sixth century B.C., Ezekiel [xx. 28, 29] is found reproaching them for still presenting the provocation of their obscene offerings to "every high hill" and "all the thick trees." Notable trees are always associated with the phallic pillars* and hills mentioned in the Bible, just as in all other records. Thus, Joshua [xxiv. 26] set up the stone which was to bear witness to the covenant between Israel and God [literally, "the gods"], under the famous oak at Sichem [Genesis xxxv. 4], to be known thereafter as "the oak of the pillar" [Judges ix. 6], and "the oak grove of enchantments" [Judges ix. 37, where the English text of the Authorised Version has "plain of Meoneim," and the margin "the regarders of times" and seasons, *i.e.*, astrologers]. *Allah* is the Hebrew word in Joshua xxiv. 6, translated in the English Bible by "oak"; and it is the same word as occurs in Joshua xix. 26, and is left untranslated in the Authorised Version, as the name of a place, Alammelech, *i.e.*, "The Royal Oaks." In Genesis xxxv. 4, the Hebrew word translated "oak" is *elah*, and it is rendered by "oak" also in Judges vi. 11, 2 Samuel xviii. 14, 1 Kings xiii. 14, 1 Chron. x. 12, and Ezekiel vi. 13; and by "elm" in Hosea iv. 13; by "teil-tree" in Isaiah vi. 13; and by "plain" in Genesis xiii. 18. It is used also untranslated as a proper name: "Valley of Elah" in 1 Samuel xvii. 2 and 19, and xxi. 9. The word is everywhere supposed to mean the terebinth tree, and is so translated by the Septuagint. On the other hand, the Hebrew *allon* of Joshua xi. 16, translated by "plain," and of Genesis xxxv. 8, where it is translated by "oak," is like *allah* undoubtedly the oak; and as the *allon* of Joshua xi. 16 would appear to refer to the same tree as is indicated by the Hebrew *elah* in Genesis xxxv. 4, great uncertainty is felt as to whether the oak or the terebinth is meant by the Hebrew word *elah* as it occurs in the Old Testament.

But the interesting point, never, I believe, before remarked upon by any English writer, is that all these words, *allah*, *elah*, and *allon*, and the other Hebrew words, *el*, *ilon*, and *elan*, translated in the English Bible (A.V.) by the words "oak" "plain," and "trée," are all really one word, formed from the same root as the words *el*, *eloah* (Arabic *Allah*), "God," and *elohim*, "gods"; and it is just possible that, as used in the Bible, they are not meant, or were not originally, to distinguish the trees indicated by them botanically, but simply as holy objects, the groves of the autochthonous gods, and, indeed, the local gods themselves, of the places where they grew up, and which became remarkable by their presence, and the centres of the phallic worship the broad shadows of these trees attracted; and thenceforward, in every country, the centres also of its special religious and artistic culture. This is probably how Hellenic culture grew up round the oak groves of the dale of Dodona, and in the shelter of the pine-woods of Mount Olympus; and how the Scytho-Semitic civilisation of Chaldæa and Assyria and

* Compare collis, clumen, columen, and also the word columna as used by Martial, vi. 49. The Bible records no direct evidence of the worship of trees in Old Testament times, but indirectly affords overwhelming evidence of it, and its universality. See besides the passages noted in the text—Jeremiah ii. 20; iii. 6, 13; xvii. 2; Ezekiel vi. 13; xx. 28, etc.

Babylonia had its beginnings at Eridu, under the date trees that still wave in perennial verdure over the Tigris and Euphrates at the auspicious confluence of these "waters of Babylon" in the Shat-el-Arab.

These date trees are the antitypes of the Akkadian mystical Tree of Life; and of all Paradisaical trees alike of Hindus, Persians, and Norsemen. In the famous bi-lingual, brick-inscribed text, from the library of Assurbanipal [Sardanapalus, *circa* B.C. 668–40] at Kouyunjik, of the hymn on "The Seven Evil Spirits," the Akkadian and Assyrian words used to designate the Edenic tree of Eridu are translated [" Records of the Past," ix. 1437] "dark pine" by Professor Sayce:—

"[In] Eridu a dark pine grew, in a holy place it was planted,
Its [crown] was white crystal which towards the deep spread.
The [a lacuna] of Hea [was] its pasturage in Eridu, a canal full [of waters].
Its seat [was] the [central] place of this earth,
Its shrine [was] the couch of [*the primæval*] mother Zicum.
The [a lacuna] of its holy house like a forest spread its shade; there was none who within entered not.
It was the seat of the mighty, the mother [Zicum], beggetter of Anu.*
Within it [also was] Tammuz † [a lacuna] the universe [a lacuna]."

If the Akkadian and Assyrian names of the tree really mean "a dark pine," a very deep interest indeed attaches to them, as indicating that the Akkadians ["Mountaineers"] of Chaldæa still preserved among themselves the memory of a previous connection with some northern country to which coniferous trees were indigenous: for no species of them exists in the valley of the Tigris and Euphrates, where the date palm is, however, everywhere the most characteristic vegetable form. In Assyria, the oak, poplar, walnut, plane, and sumach are also found; but in Babylonia, if I may judge from the banks of the Shat-el-Arab, along which I botanised for more than a week in 1856, the only true native tree is the date palm; the occasional acacias, poplars, and tamarisks seen along with it being very dwarfed and scrubby. About Mohammerah and Bussorah, halfway between the head of Persian Gulf and the confluence of the Tigris and Euphrates,* the date palm attains the noblest proportions, and occurs in dense groves extending for miles along both sides of the river. The intermediate glades of grass are all over enamelled with buttercups and deep blue pimpernels, a combination of temperate with tropical vegetation perfectly enchanting to the eye, and that transported me with the feeling of the ground whereon I stood being still as fresh and bright as when first planted by God, with what were, according to the Semitic legend, trees and herbs of heaven before they became trees and herbs of earth; and indeed none other than "the Gate of Eden." In the enclosed gardens also were the fruits both of northern and southern climates, apples, and plums, together with pomegranates, oranges, and vines, the latter often trained up the stems of date palms, set in rows for the purpose. The vine does not ripen its clusters where the mean temperature of the year is higher than 84°, and the date will not flourish where it sinks below 84°, and it is remarkable that these conditions meet exactly in Palestine and Mesopotamia, the only two countries wherein the vine and the palm are found growing together in natural fruitfulness and luxuriance. When we turn to the monuments of Babylonia and Assyria, it becomes perfectly clear that the Tree of Life, so universally adored, and, as I have elsewhere elaborately demonstrated, so universally reproduced in decorative art from the remotest ages in the East, is nothing but the palm—

"Encinctured with a twine of leaves,"

representing at once the Soma plant and the vine. Originally it was worshipped by the Turanian Akkads at Eridu, as a phallic symbol, the palm representing the male principle in nature, and "the fruitful vine," when trained round it, the female. Afterwards, during the time of Hamitic predominance in Chaldæa, a higher astronomical, or rather astrological, significance was given to it; while, under the Semites, it became associated with Nana or

"Thammuz yearly wounded,"

and the Adonis of the Greeks, who is torn away from Ishtar in the flower of his adolescence, and recovered by her from the gloom of Hades; as told in the Akkadian songs from the *Idzubar Legend*, entitled "The Descent of Ishtar." These "amorous ditties" are an obvious myth of the sun in his southern declination over the Indian Ocean, similar to the Deluge myth.

* The junction of the two rivers is more like a portage than a confluence, for it may be said to extend from Swaije on the west—in a prolonged reach of over sixty miles, almost coincident with the thirty-first parallel of northern latitude—due east to Kurnah; and this reach is the river "that went out of Eden to water the garden." Eridu may be identified with the present village of Abu-Shahrein, about ten miles from the right bank of the Euphrates, south of Swaije.

Ishtar, the Ashtoreth of the Sidonians, and with Asshur, and, it may be presumed, also with the supreme deity of the Babylonians, Il [Hebrew *Eloah*; Arabic, *Allah*]; for Babil—"the Gate of God"—the Semitic name of Babylon, is said to be an idiomatic translation of its Akkadian name, Ka-Tintira, Ka-Dingira, or Ka-Dimira, "the Gate of the Divine Tree." Thus, even if it never really was a symbol of abstract deity, it was at once not only a phallic tree, but the mystic emblem of cosmical life, terrestrial and celestial, in man and beast and bird, and in trees and herbs, and in the sun and moon and five lesser planets, and the twelve constellations of the Zodiac, and all the hosts of the fixed stars, for ever shining beside the banks of the "Milky Way," the heavenly Euphrates [*cf.* Eridanus], after the similitude of the vine-clad palm of Hea, by the waters of Eridu. It is identical, historically, with "the Tree of Life," and "the Tree of Knowledge of Good and Evil," of the Hebrew myth of Eden; and it probably suggested "the Tree of Life," of St. John's vision [Revelation xxii. 2], "which bare twelve manner of fruits, and yielded her fruits every month, and the leaves of the tree were for the healing of the nations"; and which, whatever it may typify in the Apocalyptical sense, is a sublime poetical figure of the sun as "the giver of life," moving in his annual circuit through the twelve signs of the Zodiac. I believe also that the conventional Assyrian representations of "the Tree of Life" will be found to be directly connected with the Thyrsus of Bacchus, and the Maypole.

Canon Rawlinson, in "The Speaker's Commentary on the Bible" [vol. iii. 369], suggests the identification of Semele with a hypothetical female form of an obscure Assyrian god, Semel, whose name is said to occur several times in the Bible, in the original Hebrew, as in Deuteronomy iv. 16, where the English Authorised Version translates it "figure," and 2 Kings xxi. 7, and Ezekiel viii. 3 and 5, where it is translated "image," and 2 Chronicles xxxiii. 7, where it is rendered "idol." Again, Professor Sayce, writing in the *Athenæum* of September 26th, 1885, of her identification as the wife of Semel, as quite independently suggested by himself in the *Athenæum* of September 12th precedent, observes that she seems to have been the goddess of the grape, among some of the close neighbours* of the Assyrians, who was consumed by fierce heat of the sun in giving birth to the wine-god Dionysos. The etymological meaning of the word *semel* in Assyrian is really image, and Semel was probably a local rural deity, analogous to the classical Priapus, and worshipped with other divinities, into whom he would appear to have been rapidly absorbed, under the form of the *asherim*, or reduplicative images of "the Tree of Life" of Eridu.

It seems to me from the elaborations of the topography of Mount Meru by the Hindus, and of the Aryana-Vaego by the Iranian Persians, that they must have been in some degree directly suggested by the Chaldæan myth of Eden; but I do not think that there can be any direct connection between the latter and the Norse myth of Asgard. Still less is it probable that, even if the original Tree of Life of the Akkadians was "as dark pine," "the Christmas Tree" of the Germans and English was derived directly from it. The latter one would presume to be rather connected with the Yggdrasil tree of the Norse myth, and to have been substituted for the ash at Christmas by the converted Germans, because its evergreen foliage made it a more appropriate decoration at this season of the year. At the same time, Professor Sayce's translation of the Akkadian verses on the Tree of Life does suggest that the custom of using pine trees in connection with religious observances may have been introduced from the beginning by some Aryan or Turanian tribe, coming into Europe direct from the Alpine regions of Asia, where pines constituted the principal vegetation. It must not be overlooked, in this connection, that Gothic architecture* has been as much influenced by the pine form as classical architecture by the palm form; the Ionic column in particular, and all that is Ionic in Greek architecture, being directly taken from the central conventionalised palm shaft, and circumferential trellis of vine leaves, of the Assyrian *asherim*, or images of the "Tree of Life." The Turanian architecture of Buddhism, as represented more especially by the seven-roofed pagodas of Further India and China, seems also as if it might have been suggested by different species of pine trees, as seen in silhouette; although their sacramental construction in seven storeys betrays the direct inspiration received from Chaldæa, whence all the now world-wide ideas of the good and bad luck of certain numbers are derived; these ideas having originated in the astrological study by

* The original habitat of the vine is the slopes of the mountain ranges stretching from the Caspian Sea southward to the valley of the Tigris and Euphrates, and in the Persian portion of this region its vernacular name is *dims*.

* The German Christmas *Baum-Kuchen*, or "Tree-cakes," modelled after the fir-tree, might be well synonymed "Pagoda-cakes," so closely do they take the shape of Chinese pagods.

the priests of that country of the different numeral aspects of nature—such as day and night (2); heaven, earth, and the under-world (3); the four (4) quarters of the sky; the seven (7) planets; the twelve (12) signs of the Zodiac.*

For my own part, I was very early led to identify "the Christmas Tree" with "the Tree of Life," and chiefly from having been accustomed to entertain my native Indian friends, of all religions, on Christmas Day. I have always found them a good deal better Christians than myself; but, apart from that, I had to make my tree a symbol of universal charity and religious reconciliation, and of pan-Aryan brotherhood: and this is how I did it. I placed some green bush on a mound, resting on a coiled serpent or dragon. The mound was Mount Meru, Hara-Berezaiti, Olympus, Asgard, the anonymous Akkadian mountain of Paradise, Mount Moriah,—the world itself. At the top of the tree I fixed the symbol of the universal empire of Christianity, wherefrom flowed down all over the tree seven differently-coloured streamers symbolising the seven Christian virtues. Next in order came representations, in their proper colours, of the seven planets †:—Saturn, black; Jupiter, orange; Mars, red; the Sun, gold; Venus, "Neapolitan yellow"; Mercury, blue; and the Moon, silver. Outside these I arranged the circle of the Zodiac, the six signs representing obsolete southern winter, or monsoon suns, *viz.*, the Bull, the Crab, the Virgin, the Scorpion, the Goat, and the Fish, in frosted silver; and the six signs representing obsolete northern summer suns, *viz.*, the Ram, the Twins (*i.e.*, sun and moon), the Lion, the Scales, the Archer, and the Water-bearer, all in burnished gold. Then succeeded the Vedic Hindu gods, the Greek gods, and the Egyptian and Assyro-Babylonian gods, the tree itself representing the Turanian phallic symbols. The tree was also loaded with fragments of all the noblest products of the earth, and with gifts, and illuminated with 84 [$7 \times 12 = 84$] lights, representing the hosts of heaven in their 84* constellations. Returning again to earth, I there set a group illustrating the terrestrial scene of the Nativity; while, from under the mound supporting the tree, issued four silver-blue ribbons to the four corners, or four sides of the table, whichever corresponded with the four cardinal points, representing the four rivers of Paradise. Before it stood, not the Cherubim barring the way to the Tree, but the familiar image of Father Christmas, welcoming all to it. Beneath all was spread a sheet, patched, like "the ancient" of the P. and O. Company, of red, yellow, blue, and white, the Hindu coloration of, respectively, the East, South, West, and North [sometimes rendered in black], "imagined corners" of the Earth and Space; the Hindus, as Sun worshippers,† taking the four quarters of the compass in this circular, right hand order, and not in the cruciate order adopted throughout "Christendy."

It can be made of the simplest and cheapest materials, or the costliest, and in either is equally interesting: for, thus constructed, the Christmas Tree is no longer an accidental, almost chaotic decoration, but is instinct with meaning, understanded at a glance. It was a little shocking at first to the orthodox. But its charity is not strained. It is not only a tree of reconciliation, but an object-lesson

* The most mystical of these numbers were, and, in India, still are, 3 and 7. Ausonius [Griphus, Idyll. 11], running in 90 lines through the notable triplices of his date, begins :—

"Ter bibe, vel totiens ternos; sic mystica lex est,
Vel tria potanti, vel ter tria multiplicanti,"

and ends the list, line 88 :—

"Ter bibe; tris numera super omnia; tris Deus Unus."

† This is the order and colouring of the planets by the Chaldæans, who were the inventors of the days of the week. It has always puzzled people that, the Chaldæan order of the planets—which is the natural one, on the supposition that the earth is the centre of the solar system—being, as here given, the order of the days of the week should be so different. The explanation has been preserved in India. Not only each day of the week, but every hour of each day was, and in astrology still is, sacred to one of the above planets. Well, beginning with Saturday, the first day of the Chaldæan week, its first, eighth, fifteenth and twenty-second hours are each dedicated to Saturn, the twenty-third hour to Jupiter, the twenty-fourth to Mars, and the first hour of the following day to the sun, and, therefore, the second day of the week is Sunday. Proceeding in the same way, the third day is Monday, the fourth Tuesday, the fifth Wednesday, the sixth Thursday, and the seventh Friday. The Jews, to separate themselves from the surrounding Gentiles, made Sunday the first day of the week, keeping Saturday as their Sabbath, while the Christians, in commemoration of the resurrection of our Saviour, made their Sabbath on Sunday.

* In India, where everything in heaven has its duplicate on earth, the rural villages have been popularly arranged from the very earliest traditions of the people in groups of eighty-four [*chaurasi*], similar to our "hundreds," a very plain indication of a primitive connection between Chaldæa and India. See Edward Thomas in Marsden's *Numismata Orientalia*, new edition part i., "Ancient Indian Weights," p. 20 (Trübner).

† Most solemnising is the simple Hindu worship ["ad galli cantum," and "matutinus"] of sun-rise—as also of sun-set ["ad incensum lucernæ"], but I never saw a temple in Western India that appeared to be oriented intentionally. They all seemed to face East, South, West, and even the North indifferently. But when a temple happened to face the East, and being well open to the East, the suddenness, due to the short twilight of India, of the up-spring of the sun, and the impact of its beams on the shrine, flashing like shafts winged from the golden bow of the god, Surya, of "the thousand-rayed quiver," the effect was dramatically moving, and only passed off as with the rapidly spreading illumination of the whole heavens one's feelings and thoughts relapsed into their preoccupations under "the light of common day."

in mythology, and in the history of the evolution of religious ideas, learned at once, and then accepted ungrudgingly. The effect on my Indian friends was always electrical. They experienced an intellectual sympathy with Christianity they never knew before; and when at parting I presented them with a duly "teinded" Yule log, to carry away with them wherever they went the Promethean seed of fire, as the living symbol of pan-Aryan unity, I knew they had spent with me the very happiest day of their lives.

Primitive Christianity did not hesitate to accept not merely the symbolism, but even the teaching of the heathenism in the midst of which it gradually assumed its present ecclesiastical organisations. Those, of course, who regard the dogmatic creeds of Christendom as of divine revelation, in the narrower technical sense of the word, explain those obligations of ecclesiastical Christianity to paganism, more especially to that of ancient Chaldæa and Egypt, by the assumption of a primitive revelation, wherefrom mankind at once fell away, and whereto they had to be brought back by renewed special revelations. But those who see in "the faith once delivered to the saints" the results of historical evolution, or divine revelation in the proper sense of the phrase, will recognise in the cosmological fables and dark moral parables of the demonolatrous Akkadian "psalmists" the first half-articulated religious conceptions to which our technical theology has merely given the more definite and precise expression dictated at different dates by the circumstances determinative of the successive steps of the whole course of the civilisation of the Old World throughout the past four thousand years.

"As little children lisp, and tell of heaven,
So thoughts beyond their thought to those high
bards were given."

Christianity is essentially a chastening and redeeming influence, inherently as independent of forms and dogmas as it is reverently observant of all such as can be used for working out the spiritual salvation of the world; and before a fixed organisation was imposed on it, and extraneous events brought it into deadly conflict with imperial Rome, and infected it with a self-protective leaven of exclusiveness, it associated itself, with the large-hearted freedom, prompted by an intuitive sense of its Catholic truth, with whatsoever was intrinsically honest, just, pure, lovely, and of good report, or of any virtue and praise, not merely in the latent doctrines, but also in the open, palpable iconography of the surrounding heathen, giving to these beautiful "spoils of Satan," as Keble, unconsciously plagiarising the language of Akkadian dualism, terms them, their highest significance:—

"And these are ours: Thy partial grace
The tempting treasure lends:
These relics of a guilty race
Are forfeit to Thy friends:
What seem'd an idol hymn, now breathes of Thee,
Turn'd by Faith's ear to some celestial melody."

The select races of mankind would probably have risen, each independently, in the fullness of time, from the lowest to the highest forms of religion; but the advancement of the historical Caucasian races from fetichism, atavism, and phallicism, to sabaism and polytheism, and again, through the idolatrous worship of the sun, as "the Ancient of days," to monotheism, was actually due to the direct reciprocation of religious ideas between them in the course of that cosmopolitan commerce of antiquity of which the countries of the Mediterranean Sea and the Indian Ocean were the perennial fresh springs, and Egypt and Mesopotamia the head centres of exchange. The widespread comparison of religious ideas thus induced resulted everywhere in a large absorption of countless local deities into each other, and a further consolidation of a selection from them into colleges of governing gods under the presidency of one of their number, who was regarded as above the rest; and it was the worship of Bel, or Baal, the predominant national god, under varying forms and names, of the Semites of Anterior Asia, that immediately led to the gradually-perfected conception among all the Caucasian races, Aryan as well as Semitic, of one universally supreme God, to the express [literally "squeezed out"] exclusion of every other god. The commerce established between Chaldæa and the Indian Ocean and Mediterranean Sea about B.C. 2000, a date closely corresponding with that more precisely assigned by Rabbinical chronology to "the Call of Abraham" [B.C. 1921], and which became more and more intimate in the course of every century, from about B.C. 700 down to the dissolution of the Western Roman and the Persian Empires, more especially generated during the latter period those humanising conceptions of the parental relations of God with men to which the teaching of the Gospels of the New Testament gives the highest contemporary, and, if we may judge from its still unspent and unabated force, their final expression. This later trade, as organised by Psammetichus I., in Egypt, and by Nebuchadnezzar

the Great, in Babylonia, the far-reaching effects whereof were already realised by the writer of the Book of Daniel, as he witnessed its wide-spread operation in the second century B.C.,* successively accomplished its inevitable moral consequences in every country embraced by it, until about the Christian era there seemed the possibility, but for adverse circumstances that subsequently supervened, of the whole world of antiquity becoming of one cosmopolitan religion, based on a common faith in the Fatherhood of God. In India, Hinduism became internationalised as Buddhism, and Judaism as Christianity in Syria and Egypt, while in Europe classical paganism seemed also on the point of becoming transformed, through neo-Platonism, into the purest of all forms of Christianity. But then followed the overthrow of Rome and of Persia, catastrophes that gradually broke up, and in the end entirely destroyed, for three hundred years, the immemorial overland commerce between the East and the West. The East being thus, at the most critical period of its Hellenisation, cut off from the West, India rapidly relapsed into the strictest form of national and exclusive Hinduism; and the diffused humanitarian Judaism of Anterior Asia became differentiated, as Mohammedanism, from the specific type it had already assumed in the dogmatic Christianity of Europe, and permanently established itself wherever, in Asia and Africa, the vitalising Hellenic element was either deficient, as in Syria and Egypt and Persia, or altogether wanting, as in Arabia and Turkestan —inaccessible regions that to the last will remain the most formidable refuges of Islam.

European Christianity, unfortunately, through the accident of the impatience of some of its early converts of the military discipline of Rome, was at its beginning placed in opposition to the general philosophical, literary, artistic, and scientific culture of the Gentile world, and thenceforward in more or less marked antagonism also to the modern secular life of the West.

Happily, in India there is no gulf fixed in the popular belief between heaven and earth; and the Brahminical religious life has never sundered itself from the daily working life of the laity, but is a component part of it, and indissolubly bound up with it; and we may, therefore, hope that in India, under the *Pax Britannica*, Christianity, whether taught by missionaries of the churches, or, more consistently with itself, through the administration of equal laws, and the public and private example of our righteous dealing, will have the exceptional opportunity of drawing an ancient people into its fold, by its unstrained spiritual influences, illumining in them what is dark, raising what is low, and supporting and confirming all their higher ideals of duty and amenity, and without desecration or defamation of their traditional beliefs and worship, or the substitution of a foreign social system and ecclesiastical organisation for their own indigenous and sacrosanct family, municipal and national institutions; indeed, without involving any breach in the continuity of their civilisation, or any dislocation of the relations between their priesthood and themselves, such as has for a thousand years overshadowed and embittered, where it has not altogether blighted, —as in Spain, and perverted,—as in France, the progress of the West.

Thus India, the inviolable sanctuary of archaic Aryan civilisation, may yet be destined to prepare the way for the reconciliation of Christianity with the world, and through the practical identification of the spiritual with the temporal life, to hasten the period of that third step forward in the moral development of humanity, when there will be no divisions of race or creed, or class, or nationality, between men, by whatsoever name they may be called, for they will all be one in the acknowledgment of their common Brotherhood, with the same reality, and sense of consequent responsibility, with which, two thousand years ago, they recognised the Fatherhood of God, and two thousand years again before that an exceptionally endowed tribe of Semites, in the very heart of Anterior Asia, formulated for all men, and for all time, the inspiring and elevating doctrine of His Unity.

* Antiochus Epiphanes, against whom the Book of Daniel is directed under guise of an attack on Nebuchadnezzar, reigned B.C. 175-164, and the trade of which its author was the eyewitness is, as prophetically seen in its spiritual results, "the fifth kingdom" of Nebuchadnezzar's dream [ch. ii.], and the "kingdom of the saints" of Daniel's own dream [ch. iii.]; by the saints being meant the highly idealised Jewish supercargoes, brokers, and commission agents, and capitalists, into whose hands the inspired pamphleteer saw the whole contemporary commerce of Babylon daily passing.

MINERALS OF THE UNITED KINGDOM.

According to the General Report on Mines and Quarries for 1909 (Cd. 5413, Part III.), the total value of all minerals raised in the United Kingdom during the year amounted to £119,394,486, a decrease of £10,609,184, as compared with 1908. This decrease is mainly accounted for by the decreased value of coal.

The total output of coal was 263,774,312 tons,

and the value, £106,274,900, showing an increase of 2,245,517 tons and a decrease of £10,323,948 respectively on the figures for 1908. The average price of coal was 8*s.* 0·7*d.* per ton in 1909 as compared with 8*s.* 11*d.* in 1908.

The quantity of coal exported, exclusive of coke and manufactured fuel, and of coal shipped for the use of steamers engaged in foreign trade, was 63,076,799 tons, an increase of more than half a million tons on the exports for 1908. France received over 10⅞ million tons, Germany over 9⅜ million tons, Italy over 9 million tons, Sweden nearly 4 million tons, Russia nearly 3¼, Egypt, Spain, and Denmark, each over 2½ million tons, and the Netherlands and the Argentine each over 2 millions. Adding the 3,246,300 tons exported in the form of coke and manufactured fuel, and the 19,713,907 tons shipped for the use of British and foreign steamers engaged fn foreign trade, the total quantity of coal which left the country was 86,037,006 tons.

The amount of coal remaining for home consumption was 177,737,306 tons, or 3·949 tons per head of the population. 35,924,723 tons were used in the manufacture of coke and briquettes, and 19,463,471 tons in the blast furnaces for the manufacture of pig iron, as against 35,704,971 tons and 18,742,464 tons respectively in the previous year.

During the past thirty-seven years (1873-1909) the total value of the minerals raised amounts to £2,981,116,000, and of this sum coal accounts for £2,467,976,000, or 82¾ per cent.

6,856,407,000 tons of coal have been raised in that period; and of this amount 1,575,998,000 tons, or nearly 23 per cent. of the total production, have been shipped abroad as exports in the form of coal, coke, and manufactured fuel, and as coal used for steamers engaged in foreign trade.

THE ROYAL SCHOOL OF SILK INDUSTRY AT COMO.

The executive committee of this important School (Regia Scuola di Setificio)—which was established by Royal Decree in 1904 for the purpose of giving technical as well as practical instruction in the textile arts, dyeing, etc., to students wishing to qualify themselves for posts as managers, superintendents, designers, etc.—have just made an official inspection of the new building to which this institution will be shortly transferred from the present temporary premises. Beautifully situated on the Viale di Lecco at Como, the centre of the silk industry of Lombardy, the new school will be certainly one of the most important of its kind in Europe.

The laboratories for general and technical chemistry, with special reference to the art of silk dyeing, are provided with all the latest appliances and instruments of precision for testing silk, etc., as well as for experimental research. Besides instruction of students, manufacturers will be able to obtain at these laboratories reliable analysis and tests of their materials and products.

Commodious class-rooms for instruction in weaving, mechanical drawing, natural history, etc., as well as a microscopical laboratory, are also provided. Besides offices, council rooms, and an extensive technical library, nine rooms will be devoted to an industrial museum.

For practical instruction there will be weaving-sheds containing twelve hand-looms and twenty-four power-looms, as well as other machinery used in the manufacture of silk, mechanical workshops, etc. This part of the establishment will be under the guidance of a practical works-manager, who will be assisted by two competent foremen.

The course of instruction is divided into three branches, viz.:—(1) weaving; (2) dyeing, printing, etc.; (3) drawing and designing.

Evening classes will be also provided for working-men.

The instruction in the first department will embrace the following subjects:—Natural history, working of textile fibres, elements of chemistry as applied to dyeing, natural science, mechanics (including practical workshop instruction), mechanical and ornamental drawing, French, English or German, book-keeping, and the elements of commercial and industrial jurisprudence.

The instruction in the second department comprises natural history, the preparation of textile fibres, the elements of weaving, general and analytical chemistry applied to dyeing (with practical instruction), practical mechanics, French, English or German, book-keeping, and the elements of commercial and industrial jurisprudence.

In the third department instruction is given in practical weaving, ornamental drawing, designing, the history of the textile arts, French, English or German.

The course of instruction in each department covers a period of three years. The fees are very moderate, and students who pass all the examinations receive a diploma of "expert" (perito) either in weaving, dyeing, or design.

PEARLS AND THE PEARL-FISHERIES OF BAHREIN.

The whole wealth of the island of Bahrein in the north-west of the Persian Gulf depends upon pearls, and this is also true of the adjacent mainland coast-line. During the year 1909-10 the pearl trade was most flourishing. The prices averaged about 30 per cent. higher than in the preceding year, and showed an upward tendency throughout the season, enabling old stocks to be got rid of and the season's catches to be readily disposed of. Bahrein is also a centre of distribution of many articles for the mainland, the more important of these being rice, coffee, kerosene, sugar, piece goods, ghee, spices and tobacco.

But the governing factor is the pearl supply, and

this, it may be observed, is generally insufficient to meet the world's demand. Any revival of prosperity in Europe and America is immediately followed by a corresponding rise in the value of pearls. During bad years of recent date enormous drops have, no doubt, occurred, and when money is scarce pearls have been a drug on the market. But, on the other hand, the average price of good quality pearls during the last thirty years has quite doubled. In considering the future possibilities of Bahrein it is worth noting that its population is close on 100,000 inhabitants, and all signs seem to point to an increase for the next ten to twenty years, at the rate of about 3 per cent. per annum. This increase is chiefly in the poorer classes, who are attracted from other countries by the comparatively high rates of wages, and the freedom from oppression due to British protection. But though the increased use of luxuries during the last few years has been noticeable in the town of Manama, and among the richer inhabitants of Bahrein, consequent upon their visiting Bombay to dispose of their pearls, no symptoms of general improvement are observable in the lot of the poor, who continue to live contentedly in their mat and palm-date huts.

The rise in the cost of living continues steadily. Captain C. F. Mackenzie, the Political Agent, says he has been told by old inhabitants that some forty years ago the richest people in Bahrein only owned about £5,000, while at the present time there are one or two whose property is valued at £66,000, and several are worth between £6,000 and £7,000. The increase in cost of living during the same period has amounted to about 400 per cent., this being due almost entirely to necessities of life having increased in value, and also to a larger consumption of rice, flour and animal foods, in addition to the cheap dates which years ago formed a much greater percentage of their staple food than now. From this point of view, therefore, an increase in the money value of the trade may be expected.

Beyond pearls there is only one article which can be termed a natural export, and can help in the prosperity of Bahrein, and that is the pearl oyster-shell, which is exported in large quantities to Hamburg. Formerly these shells were shipped to London, but owing to better machinery and greater facilities (thirteen of the Hamburg-America steamers having touched at Bahrein during the year) practically the whole of the trade has been transferred to Hamburg. The trade is now nearly at its zenith as regards quantity, but it will probably improve in value.

Captain Mackenzie remarks it is a pity that no British firm can see their way to sending a representative to Bahrein for the pearl season. He mentions, in illustration of the sort of business that might possibly be done, the case of a member of a Paris firm, who has regularly come to Bahrein for the last four seasons, and whose transactions have amounted to £12,000, £23,000, £36,000, and £266,000 respectively. This includes buying and reselling perhaps three or four times in the course of the season, so the actual capital employed was not nearly so much. He is able to get the best available information by telegraph direct from Paris, which enables him to effect his transactions on much more substantial grounds than his rivals. The profits made by him last year were estimated at about 6 lakhs of rupees (£40,000), results which, although effected in an exceptionally favourable year, have induced his firm to send out another representative to Debaï.

HOME INDUSTRIES.

Passenger Ships and Life-Saving Appliances.—Some misconception has been caused by the model of the "Olympic," of the White Star line, now to be seen at the Piccadilly Hotel. This model shows only sixteen boats, fourteen life-boats and two dinghies, and it has been pointed out that this is a quite inadequate number of boats for a vessel carrying 3,400 souls. At most not more than sixty persons could be safely carried in each boat, which means that the "Olympic" ought to have fifty-six boats if, with a full ship, all have to leave her. It is not alleged that in addition to the sixteen boats there are to be collapsible boats and rafts, and if they were provided they would not be a satisfactory substitute for life-boats. But inquiry shows that there is no ground for alarm. It was, of course, highly improbable that the White Star line would send a 50,000-ton passenger ship to sea without a proper number of boats, and very unlikely that they would rely, or be allowed to rely, upon the theory that the vessel will be unsinkable. The unsinkable ship has still to be constructed. The fact is, that whilst the model only shows sixteen davits, they are to be quadrant davits, that is to say, each will be able to carry four boats, which means sixty-four boats in all, an ample and even excessive provision against disaster. It should, however, be pointed out that this full supply of boats is not required by law. The Board of Trade is supposed to inspect every new vessel before she leaves port, for the purpose of seeing, among other things, that she has adequate boat accommodation to carry the full complement of passengers and crew, and the rule defines with precision what is considered adequate. But this very important question has not been dealt with by the Government for years. There is a statutory maximum, and the boats of every ship above 10,000 tons are settled separately. But this means chaos. The present maximum was fixed at a time when a 10,000-ton steamer was a very rare vessel, the great majority of even the largest passenger steamers being of smaller tonnage. The "Olympic" is to be of 50,000 tons, yet the maximum, as laid down by the Board of Trade, is unchanged. It is obvious that a maximum which might have been, and no doubt was, quite adequate to the requirements of safety when there were no vessels over 10,000 tons, must be quite inadequate for vessels of

40,000 or 50,000 tons; and it may be hoped that, now its attention has been called to the matter, the Board of Trade will lose no more time in revising the regulations that deal with boat accommodation. There are several other matters connected with life-saving at sea which require the prompt attention of the Government. For example, it is useless for a vessel to have the best conceivable boats if they cannot be promptly and safely lowered into the sea. This can only be assured if the lowering gear is constantly inspected and tested, and there is good ground for the belief that this most important duty is neglected on many passenger ships, where, if the life-boats had to be lowered suddenly, it would be found that the gear would not work, and if ultimately they got into the water as likely as not the boats would be found to be unseaworthy.

The Port of Manchester.—The growth of Manchester as a port continues. A few days ago the latest and largest of the Manchester docks, No. 9 Dock, Salford, had all its berths, on both sides of the dock, occupied by steamers loading and unloading cargo. The magnitude and variety of the trade may be indicated by some particulars of the vessels in the dock. One steamer, of 3,174 tons, was discharging grain from Karachi into the transit sheds. Another, of 2,636 tons, was discharging a cargo of paper and pulp from Newfoundland. The paper was conveyed to warehouses for local distribution, whilst the pulp was distributed by rail and barge to Lancashire paper mills. A third steamer, of 3,253 tons, was taking on board a cargo of Manchester piece goods and general merchandise for Bombay, and a fourth was receiving similar cargo for the Persian Gulf, Port Sudan, and other Red Sea ports. A fifth was discharging cotton from Alexandria, and a sixth was passing into the sheds a heavy general cargo, which included a large consignment of American apples for the Christmas market. At the open quay a full cargo of timber was being discharged on to the wharf and into the railway trucks *ex* a steamer from Riga, whilst another, from Baltic ports, was landing timber and wet pulp. A Glasgow steamer had brought a cargo of redwood planks from that city for delivery to firms in the Manchester district, and a sailing vessel was berthed at the quayside, whilst a banana boat was in dock having her refrigerators overhauled.

Wheat Growing.—The experience of 1910 has shown that farmers were premature in assuming that the price of wheat would remain at figures which mean profitable cultivation. The markets of the two or three preceding seasons had been so favourable, and so strong was the confidence in the future, that the restoration of inferior grass land to tillage had been contemplated if not actually begun. But the adverse changes in the wheat and barley markets have caused great depression in countries where tillage is the foundation of the farming system, nor is there much likelihood of early recovery in prices, seeing that the World's wheat crop in 1910 comes out very nearly as large as in 1909—viz., 459,100,000 qrs. against 459,300,000 qrs. The consumption requirements of both years were much below these figures, so that at the present time there is more than sufficient wheat in the world for its wants. It was too hastily assumed by our farmers that the remarkable shrinkage in the wheat exports from the United States must mean considerable and permanent improvement in prices. Insufficient allowance was made for the great expansion of the area under wheat in Russia and the Argentine, not to speak of the Dominion. It seems probable that in normal seasons, and for many years to come, the supply will be fully equal to the demand, and that prices in the wheat market will not leave a satisfactory margin of profit for the English grower.

Fires and Sprinklers.—It may be taken that 1910 will show good results in the case of most British fire insurance companies. Losses abroad have been comparatively light, and in the United Kingdom there have been few very serious fires. For some years past the fire offices have shown a very low home loss ratio, and this favourable experience is attributed largely to the growing protection of a great variety of risks with automatic sprinklers. The installation of these appliances in this country was for many years practically restricted to textile factories, but during the last few years they have been freely installed in a much wider variety of buildings. Experience seems to show that the substantial allowances made where sprinklers are in use are warranted.

The Australian Wool Clip.—In the season 1909-10, ended on the 30th June last, the exports of wool from the Commonwealth amounted to 1,921,705 bales, a record clip. But this year shows a large increase even upon these figures. A splendid season, a larger number of sheep shorn, good lambing, and the greater weight of wool cut from the sheep, have combined to produce a clip for the present season of about 2,125,000 bales, and this is about what the export may be expected to be. Since the lists were closed for the last London auctions, the arrivals have amounted to 118,417 bales, of which 60,000 bales have been forwarded direct from ship to consumer. Of the total, more than 44,000 bales are from South Africa, and exports from the Cape during the present wool year, which ends on December 31st, will show a big advance on 1909. On January 17th the first London auctions for 1911 will begin, and it is expected that about 200,000 bales will be available, including the 8,000 bales brought forward from the last auctions. Bradford will be in no want of wool this season.

Malleable Iron.—The malleable ironmakers, or most of them, in the west of Scotland have held another meeting to discuss the formation of a pool,

but have again adjourned without an agreement being arrived at. The sixteen firms which constitute the West of Scotland Malleable Ironmakers' Association, have been considering a scheme which would allot them shares in the production on the basis of their past output. Any excess of tonnage over these allotments would require the payment of a certain sum per ton into the pool, out of which those firms whose output failed to come up to their allotment would be compensated. This novel arrangement was intended to apply both to the home and export trades, but there are many difficulties in the way of its acceptance, not the least being the keen competition of some half dozen outside concerns. It is probable that if an arrangement is ultimately arrived at it will, anyway at the outset, embrace only the home trade.

NOTES ON BOOKS.

COMPULSORY WORKING AND REVOCATION OF PATENTS. By Ernest Lunge. London: Stevens and Sons, Ltd., 1910. 3s. 6d.

Mr. Lunge was one of those who objected to the system of compulsory working introduced by the Patents and Designs Act, 1907. His present work, while intended chiefly as a handbook to the practice and procedure under the Act, is also to a considerable extent a protest against the principle. It is evident that the author has found nothing in the two years' experience of the Act to modify his opinion of it. The first chapter of the book is an interesting antiquarian disquisition on the origin of the patent grant. Mr. Lunge quite correctly points out that the original condition for the grant was the working of the monopoly, not novelty of invention. The analogy, however, between the old idea of rewarding the introducer of a new industry—basing that reward on the fact that the industry was really introduced—and the modern notion that a man who has obtained a monopoly for his new invention should not be permitted to exercise that monopoly in restriction of the public rights, but should be compelled to work his invention in the country—this analogy, it must be admitted, is somewhat strained. But Mr. Lunge's notes on the ancient system are none the less interesting. The Tudor grants of patents of monopoly were sometimes merely benefactions to court favourites, but were in the main actually intended to encourage the introduction of new manufactures. Such manufactures were sometimes *inventions* in the old sense of the word, that is to say, the introducer had found an industry flourishing abroad and had brought it into this country; and sometimes *inventions* in the modern sense of the word, that is to say, he had discovered a new device or method of manufacture. The former were the more numerous and the more important. Then in 1623 the Statute of Monopolies was passed to restrict the abuses which had encumbered the practice, and monopolies were abolished, except to reward the introducers of new manufactures. The result was the growth of the whole patent system, which was turned into a means of rewarding and encouraging scientific and technical discovery, and the original reason for the granting of monopoly patents entirely disappeared.

There is a good deal of work which might yet be done on the early history of the Patent Grant. Mr. E. W. Hulme, the Librarian of the Patent Office, has done much; but, so far as is known to the writer of the present note, no effort has yet been made to complete the very valuable, yet defective, list of early patents published by the late Bennet Woodcroft after the first great reform of the Patent Law in 1852. The chronological index of old law patents commences with the year 1617. This is merely an arbitrary date, which appears to have been arrived at from the fact that a certain record of grants under the Great Seal, known as the "Docquett Booke," was begun in that year. Notices of the earlier grants must be sought for in the various indexes of the Public Record Office and in the published calendars of State Papers. Nor is Mr. Woodcroft's index quite complete for the period it professes to cover, no notice being taken of petitions for protection of a less formal nature than Letters Patent under the Great Seal. In olden days the royal protection was conferred in different ways, and it will probably never be possible to make anything like an accurate list of the ancient grants. Perhaps such a list would serve no useful practical purpose, but it would be of considerable historical interest.

The second chapter, on "Compulsory Working in the Present," deals with the modern practice in foreign countries, and includes a little discussion as to the bearing of the system on the great question of Protection *v.* Free Trade. The rest of the book treats of the procedure and practice under the Act.

GENERAL NOTES.

COTTON FROM BRAZIL.—In considering the sources of cotton supply outside the southern states of America, the potentialities of Brazil are often overlooked and underestimated. Mr. H. Priestley, who has just returned from the cotton-growing districts of Brazil, directs attention to them. It will surprise many to be told, on his authority, that there is a larger cotton-growing area in Brazil than in the United States, although the amount of cotton actually grown in Brazil is barely one-third the quantity grown in the United States. Millions of bales more could be grown in Brazil if the cotton users of Lancashire would only interest themselves in the matter. The Germans are quite

alive to the possibilities of the country in the way of cotton growing, and within the last four months a wealthy German syndicate has secured three large tracts of land in three of the cotton-growing provinces of Brazil. Mr. Priestley says (and he has had practical experience in cotton growing in one of our colonies from which much is expected, namely Northern Nigeria) cotton grows beautifully in Brazil. There are practically no pests, and, if native labour is not very abundant, plenty of Italians are available. Brazil would seem to offer the most promising field for cotton growing outside the United States.

THE TRANSVAAL GOLD OUTPUT. — The figures bearing upon the gold output of the Transvaal for 1910 bear eloquent testimony to the growth of the gold-mining industry in the Transvaal. In his first edition of "The Gold Mines of the World," published in 1902, Mr. J. H. Curle predicted that before very long an average yield of £25,000,000 might be expected. In the year prior to the war the output was valued at £15,141,376. In 1908 the value had risen to £28,810,000. It is estimated that the value of the output for 1910 will reach £31,850,000. For the eleven months ended November 30th, it was £29,280,137. Prior to the war, as now, the problem how to get a sufficient supply of native labour was one of the most difficult with which the mining authorities were concerned, and, notwithstanding the greater use of labour-saving appliances since the war, the rapidly-growing output has required an ever-increasing number of native labourers. Before the war there were about 80,000 able-bodied natives working in the Rand mines, and, for each new stamp dropped in a mine, ten more natives were needed to supply it with ore. Writing in 1902, Mr. Curle assumed—as so many new mines would soon be starting work—that by 1904, 150,000 men would be needed in the Rand, but at that date nothing like that number were at work, and Chinese were imported. The Chinese have now been nearly all repatriated, and last month the number of natives at work in the mines was 178,027, an increase of some 29,000 upon the figures of 1909.

THE LIBRARY.

The following books have been presented to the Library since the last announcement:—

Baker, Richard T., F.L.S., and Henry G. Smith, F.C.S.—A Research on the Pines of Australia. Sydney: W. A. Gullick, 1910. Presented by the Authors.

Baring-Gould, S., and C. A. Bampfylde.—A History of Sarawak under its Two White Rajahs, 1839–1908. London: Henry Sotheran and Co., 1909. Presented by the Publishers.

Barr, Thomas, B.A.—Practical Mathematics for Continuation Classes. London: Blackie and Son, Ltd., 1910. Presented by the Publishers.

Bayley, Edric.—The Borough Polytechnic — its Origin and Development. London: Elliot Stock, 1910. Presented by the Author.

Berry, T. W.—The Pedagogy of Educational Handicraft. London: Blackie and Son, Ltd., 1909. Presented by the Publishers.

Bruce-Williams, Marshall.—1. Maxims of Life and Government. 2. Principles of the Science of Organisation. London: Chapman and Hall, Ltd., 1910. Presented by the Author.

Burton, W., M.A., and R. L. Hobson, B.A.—Handbook of Marks on Pottery and Porcelain. London: Macmillan and Co., Ltd., 1909. Presented by the Publishers.

Chailley, Joseph. — Administrative Problems of British India. Translated from the French by Sir William Meyer, K.C.I.E. London: Macmillan and Co., Ltd., 1910. Presented by the Publishers.

Chambers, F. W., and A. J. Ker.—Words: their Origin and Use. Books I. and II. London: Blackie and Son, Ltd., 1910. Presented by the Publishers.

Chambers, R. W.—Catalogue of the Dante Collection in the Library of University College. London, 1910. Presented by the Compiler.

Cropper, L. Cuthbert, F.C.A.—1. Book-Keeping and Accounts. 2. Elementary Book-Keeping. London: Macdonald and Evans, 1910. Presented by the Author.

Davey, Frederick.—The Students' Catechism on Book-Keeping. London: Butterworth and Co., 1910. Presented by the Publishers.

Day, Lewis F.—1. Nature and Ornament—Vol. II. Ornament the Finished Product of Design. 2. Alphabets Old and New. London: B. T. Batsford, 1909 and 1910. Presented by the Publisher.

Desch, Cecil H., D.Sc., Ph.D. — Metallography. London: Longmans, Green and Co., 1910. Presented by the Publishers.

Ditchfield, P. H., M.A., F.S.A.—The Manor Houses of England. Illustrated by Sydney R. Jones. London: B. T. Batsford, 1910. Presented by the Publisher.

Douglas, James, M.D.—Journals and Reminiscences. Edited by James Douglas, LL.D. New York, 1910. Presented by the Editor.

Enock, C. Reginald, F.R.G.S.—1. The Great Pacific Coast. 2. An Imperial Commonwealth. London: Grant Richards, Ltd., 1909 and 1910. Presented by the Publishers.

Fearn, J. Eaton. — Modern Photography for Amateurs. 6th Edition. London: L. Upcott Gill, 1909. Presented by the Publisher.

Freeman, Albert C., M.S.A.—Antiquity of Cremation. London: "Undertakers' Journal" Offices, 1910. Presented by the Publishers.

Gordon, Ella Mary.—White Heather. London: Elliot Stock, 1909. Presented by the Author.

Grebby, John King.—Modern Business Training, and the Methods and Machinery of Business. London: Macdonald and Evans, 1910. Presented by the Author.

Haynes, James B.—History of the Trans-Mississippi and International Exposition of 1898. Presented by G. W. Wattles, Esq.

Holdich, Colonel Sir Thomas, K.C.M.G., K.C.I.E., C.B.—The Gates of India. London: Macmillan and Co., Ltd., 1910. Presented by the Publishers.

Hooper, Luther.—Hand-Loom Weaving. London: John Hogg, 1910. Presented by the Publisher.

Howard, Albert, M.A., A.R.C.S., and Gabrielle L. C. Howard, M.A.—Wheat in India. Calcutta: Thacker, Spink and Co., 1909. Presented by the India Office.

Huggins, Sir William, K.C.B., O.M., F.R.S.—The Royal Society; or, Science in the State and in the Schools. London: Methuen and Co. Presented by the Author.

Johnston, Edward.—Manuscript and Inscription Letters for Schools and Classes, and for the use of Craftsmen. London: John Hogg, 1909. Presented by the Publisher.

Johnston, Sir Harry H., G.C.M.G., K.C.B.—The Negro in the New World. London: Methuen and Co., Ltd., 1910. Presented by the Assistant Secretary of the Society.

Jones, Frank, B.A.—A First English Course. London: Blackie and Son, Ltd., 1910. Presented by the Publishers.

Kain, Albert.—Hungary. Budapest: Published by the Royal Hungarian State Railways, 1910. Presented by the Hungarian Society.

Laurie, A. P., M.A., D.Sc.—The Materials of the Painter's Craft. London: T. N. Foulis, 1910. Presented by the Publisher.

Lunge, Ernest.—Compulsory Working and Revocation of Patents. London: Stevens and Sons, Ltd., 1910. Presented by the Publishers.

McCurdy, Edward, M.A.—Leonardo da Vinci's Note-Books. London: Duckworth and Co., 1910. Presented by the Publishers.

Marlow, Thomas G.—Drying Machinery and Practice. London: Crosby Lockwood and Son, 1910. Presented by the Publishers.

Massee, George.—Diseases of Cultivated Plants and Trees. London: Duckworth and Co., 1910. Presented by the Publishers.

Metson, George.—Quantity Surveying. London: John Dicks Press, Ltd., 1910. Presented by the Publishers.

Moore, James M., M.A., and James Donaldson, M.A.—An Intermediate French Course. Part I. London: Blackie and Son, Ltd., 1910. Presented by the Publishers.

Oakenfull, J. C.—Brazil in 1910. Plymouth, 1910. Presented by the Author.

Oswald, Alfred.—Advanced Course of German Commercial Correspondence. London: Blackie and Son, Ltd., 1909. Presented by the Publishers.

Patton, William G.—Guide to Commercial Correspondence and Office Routine. London: Blackie and Son, Ltd., 1909. Presented by the Publishers.

Peckham, S. F., A.M.—Solid Bitumens. New York: The Myron C. Clark Publishing Co.; London: E. and F. N. Spon, Ltd., 1909. Presented by the Publishers.

Pilkington, Woodford, M.Inst.C.E.—Co-ordinate Geometry applied to Land-Surveying. London: E. and F. N. Spon, Ltd., 1909. Presented by the Publishers.

Prideaux, Sir Walter S.—Memorials of the Goldsmiths' Company. 2 vols. London: 1896 and 1897. Presented by the Goldsmiths' Company.

Rathbun, Richard.—The National Gallery of Art, Washington, U.S.A. Washington: 1909. Presented by the Smithsonian Institution.

Saillens, Émile, and E. R. Holme, B.A.—First Principles of French Pronunciation. London: Blackie and Son, Ltd., 1909. Presented by the Publishers.

Schlich, Sir William, K.C.I.E., Ph.D., F.R.S.—Schlich's Manual of Forestry. Vol. II.—Silviculture. 4th Edition. London: Bradbury, Agnew and Co., Ltd., 1910. Presented by the India Office.

Smith, Harold Hamel.—Aigrettes and Birdskins. London: John Bale, Sons, and Danielsson, Ltd., 1910. Presented by the Author.

Speltz, Alexander.—The Styles of Ornament, from Prehistoric Times to the Middle of the 19th Century. Translated and revised by R. Phené Spiers, F.S.A. London: B. T. Batsford, 1910. Presented by the Publisher.

Spon's Architects' and Builders' Pocket Price Book. London: E. and F. N. Spon, Ltd., 1910. Presented by the Publishers.

Tavenor-Perry, J.—Dinanderie—a History and Description of Mediæval Art Work in Copper, Brass, and Bronze. London: George Allen and Sons, 1910. Presented by the Publishers.

Temple, Sir Richard C., Bart., C.I.E.—The Thirty-seven Nats. A Phase of Spirit-Worship prevailing in Burma. London: W. Griggs, 1906. Presented by the Author.

Thompson, A. Beeby, F.G.S.—Petroleum Mining and Oil-Field Development. London: Crosby Lockwood and Co., 1910. Presented by the Publishers.

Tremearne, Captain A. J. N.—The Niger and the West Sudan. London: Hodder and Stoughton, 1910. Presented by the Author.

Watson, Colonel Sir C. M., K.C.M.G., C.B., M.A.—British Weights and Measures. London: John Murray, 1910. Presented by the Author.

Wood, Sir Henry Trueman, M.A.—Industrial England in the Middle of the Eighteenth Century. London: John Murray, 1910. Presented by the Author.

Young, G. A.—A Descriptive Sketch of the Geology and Economic Minerals of Canada. Ottawa, 1909. Presented by the Department of Mines, Ottawa.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

January 18.—John C. Medd, M.A., "The Dutch Labour Colonies." Lord Reay, G.C.S.I., G.C.I.E., will preside.

January 25.—Horace M. Wyatt, "Motor Transport in Great Britain and the Colonies."

February 1.—Philip Joseph Hartog, M.A., B.Sc., "Examinations and their bearing on National Efficiency." The Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E., Vice-President of the Society, will preside.

February 8.—Captain A. J. N. Tremearne B.A., D.Anth., "Some Nigerian Head-Hunters."

February 15.—George A. Stephen, "Modern Machine Book-binding." John Murray, J.P., D.L., F.S.A., will preside.

February 22.—Professor J. Wertheimer, B.Sc., B.A., "Water-Finders."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

January 19.—Reginald Murray, "Banking in India."

February 9.—R. A. Leslie Moore, I.C.S. (retd.) "Indian Superstitions."

March 16, April 27, May 25.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

January 31.—F. Douglas Osborne, M.Inst.M.M., "The Tin Resources of the Empire."

February 28.—The Hon. Sir Richard Solomon, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "The Resources and Problems of the Union of South Africa."

April 4.—Captain R. Muirhead Collins, C.M.G., "Australia and her Resources."

May 9.—F. Williams Taylor, "Canadian Banking."

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Frederick Wedmore, "Etching": 1. "The Old Masters;" 2. "Modern Etching." Two Lectures.

January 23, 30.

Professor Adrian J. Brown, M.Sc., "Brewing." Four Lectures.

February 6, 13, 20, 27.

Professor J. A. Fleming, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

March 6, 13, 20, 27.

Alfred E. H. Tutton, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

Dates to be hereafter announced:—

Frank M. Andrews, "Architecture in America."

Arthur Charles Davis, F.C.S., Assoc.Inst.C.E., "The Manufacture and Testing of Portland Cement."

George B. Heming, "Art Education in Jewellery and Goldsmithing."

Colonel Charles Edward Cassal, V.D., F.I.C., "The Adulteration of Food."

Dr. Leonard Hill, F.R.S., "Caisson Sickness and Compressed Air."

Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

Hal Williams, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

Noel Heaton, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

Sir Thomas Henry Holland, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord Avebury, D.C.L., LL.D., F.R.S., will preside. (Indian Section.)

MEETINGS FOR THE ENSUING WEEK.

Monday, January 2...Chemical Industry (London Section), Burlington House, W., 8 p.m. Mr. James P. Ogilvie, "The Determination of Sucrose (Cane Sugar) in Sugar Factory Products by Clerget's Process using Invertase as Hydrolyst."

Geographical, in the Theatre, Burlington-gardens, W., 3 p.m. (Juvenile Lecture.) Mr. F. T. Bullen, "Deep-Sea People at Home."

British Architects, 9, Conduit-street, W., 8 p.m. Sir Henry Tanner, "The New General Post Office."

London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. F. Martin Duncan, "Spring and its Studies."

Tuesday, January 3...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor Silvanus P. Thompson, "Sound: Musical and Non-Musical. Lecture III.—Reception of Sound."

Photographic, 35, Russell-square, W.C., 8 p.m. Dr. C. Atkin Swan, "The Practical Side of Alpine Photography."

Wednesday, January 4...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. (Juvenile Lecture.) Professor A. M. Worthington, "A Study of Splashes, conducted by the aid of Instantaneous Photography." (Lecture I.)

London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. F. Martin Duncan, "Summer—the Pageant of Nature."

Thursday, January 5...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor Silvanus P. Thompson, "Sound: Musical and Non-Musical. Lecture IV.—Combination of Sounds."

Philatelic, 4, Southampton-row, W.C., 6 p.m. Mr. A. Léon Adutt, "The Stamps of the Cayman Islands."

Friday, January 6...Women's Aerial League (at the Royal Society of Arts, John-st., Adelphi, W.C.), 3 p.m.

London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. F. Martin Duncan, "Autumn and Winter—the Web of Life."

Geographical, in the Theatre, Burlington-gardens, W., 3 p.m. (Juvenile Lecture.) Mrs. Vassalt, "An English Lady's Experiences in Annan."

Saturday, January 7...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor Silvanus P. Thompson, "Sound: Musical and Non-Musical. Lecture V.—Registration of Sounds."

Journal of the Royal Society of Arts.

No. 3,033. VOL. LIX.

FRIDAY, JANUARY 6, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 11th, 5 p.m. (Juvenile Lecture.) Professor ARTHUR MASON WORTHINGTON, C.B., M.A., F.R.S., "A Study of Splashes, conducted by the aid of Instantaneous Photography." (Lecture II.—The Splashes of Solid Spheres.)

Further particulars of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

On Wednesday afternoon, January 4th, Mr. ARTHUR MASON WORTHINGTON, C.B., M.A., F.R.S., Professor of Physics in the Royal Naval College, Devonport, delivered the first lecture of his course on "A Study of Splashes, conducted by the aid of Instantaneous Photography."

The lecturer began by showing on the screen the curious radial marks made by drops of water and mercury striking a plate of smoked glass. It was the examination of these marks by a schoolboy that first drew attention to the subject. Such a splash is much too quick to be photographed by an ordinary cinematograph. We require a spark of very short duration. The lecturer showed by means of a whirling disc that some electric flashes are not of short enough duration, but the flash of a Leyden jar discharged through thick wires is short enough and may last for not more than three-millionths of a second—quite long enough, however, to give brilliant photographs.

The apparatus was then shown by which such a spark could be produced exactly when it was wanted (within about two-thousandths of a second), and made to illuminate a splash at any desired stage. The splash takes place in a dark room with a camera looking at it, and the camera photographs the stage of the splash that has been reached when it is suddenly illuminated. Each photograph is taken from a separate but exactly similar splash, and thus the whole procedure is followed step by step.

The first photographs shown were, however, taken without a camera at all, by letting a drop of mercury fall on to the photographic plate itself and lighting it up by a spark vertically above it. From these shadow-photographs the well-ordered but complicated behaviour of the drop on striking the plate was easily followed.

It was explained, and made clear by experiments, that the surface of the liquid behaves like a stretched elastic skin which pushes back all convexities and protuberances, and pulls out all hollows and dimples. Also this skin-tension causes any cylindrical rod of liquid, or any such rod bent round into a ring, to divide or topple into a row (or ring) of equal, equidistant drops, whose number depends on the length and thickness of the rod. From the places where the drops begin to form jets shoot out, and the jets themselves topple into droplets. The smooth edge of a breaking wave, and the edge of the crater thrown up by a rain-drop falling into a pool follow the same law.

The splash of a drop falling into water was followed from beginning to end. It was seen to excavate a perfectly spherical hollow many hundred times larger than itself, over the interior of which the original liquid of the drop was spread out as a very thin lining. Afterwards this is all swept together again, and the original drop emerges at the top of a little column, which again descends and again rises.

With larger drops falling from sufficient height the crater thrown up closes on account of the surface tension and forms a bubble which may remain floating on the surface. Such a bubble is built in less than two-hundredths of a second. The big drops of a thunder-shower give rise to bubbles built in this way which often remain floating on the surface of a pool.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A Meeting of the Indian Section was held on Thursday, December 15th, 1910, Sir WILLIAM LEE-WARNER, G.C.S.I., presiding.

The paper read was—

THE TAJ MAHAL, AGRA, AND ITS RELATIONS TO INDIAN ARCHITECTURE.

By ROBERT F. CHISHOLM, F.R.I.B.A., F.S.A.

The Taj Mahal, situated in India on the left bank of the River Jumna, a short distance from Agra, is, on account of its beauty and costliness, one of the wonders of the world. It is the tomb of Argamand Banu, the favourite wife of Shah Jahan, who constructed it in the year 1631. He himself passed away in 1658, and his remains lie beside those of his queen.

The plan and section show the form of the building and the general arrangements. The building stands on a platform 18 ft. high and 313 ft. square with four minarets at the corners, each 133 ft. high. The building, which is 186 ft. square, with the corners cut off, occupies the centre of the platform.

The height of the façade in the centre is nearly 100 ft. above the level of the platform, while the apex of the dome rises to nearly twice this height. The interior contains an octagonal chamber in the centre about 50 ft. across, with passages leading to four smaller chambers at the angles. The whole of the interior and exterior consists of pure white marble inlaid with agate, bloodstone, jasper, black marble, and lapis-lazuli in that form of Florentine mosaic known as "pietra dura."

This is all the technical description of the tomb that I propose to give you, because my object in this paper is to show you wherein the secret of the great beauty of this monument lies, a beauty which is dependent not only on its immediate surroundings, but on the state of the weather, the time of day, and even the artistic discernment of the beholder, which may account in a great measure for the differences of opinion among visitors. Doubtless all buildings are affected in the way I have suggested, but when you understand the secret of the Taj you will understand why this building is pre-eminently so.

The only two points to which I would call your attention just now are, first, the difference in the outlines of the great dome and the subordinate domes, and, secondly, the fact that no work above the roof serves any useful purpose. Perhaps there is no building in the whole world which has received such extravagant praise from travellers, and no building in the world of which pictures, photographs, and models convey so poor an idea, the reason being that the high position to which most travellers raise it is due more to its unique, almost magical appearance, than to either its architectural merits or to an appreciation of its intrinsic value. In regard to its architectural merits, buildings can be found in India surpassing it in every direction: thus for size and boldness of construction the Taj falls far below the Gol Gombez at Bijapur. This building covers a square of 135 ft. 5 in.; Santa Sophia, at Constantinople covers a square of about 130ft.; St. Peter's, at Rome, about 126 ft.; and St. Paul's, London, 95 ft. In wealth of intricate detail and great delicacy of finish it is surpassed by the Jain temple at Dilwara, on Mount Abu, in Rajputana; in size, unity, and symmetrical arrangement by the great Jumna Musjid at Delhi; in constructive skill by the ingenious doming of the mosque of Sher Shah in the old Kila at Delhi; in magnitude and extent by the great Sivite Temple of Madura, South India, and in strict conformity to the canons of pure architectural decoration by the Muntapum on the building known as Jehanghir's Mahal at Agra and the Bir Bul at Fatehpur Sikri.

I was expressing somewhat similar views to a lady friend who seemed to me to be indulging in rather extravagant praise of the building, when she said, "I understand exactly what you mean, but go and see the building itself. I cannot explain it; it is unlike anything I have ever seen." Thinking she was drawing on her imagination I mentioned the matter to a very prosaic male acquaintance, who astonished me by saying, "Mrs. —— is quite right! Go and see the building; it is ghostly!" I was in no way convinced; I had seen photographs and models which did not justify such lavish praise. I merely wondered to myself, knowing its costliness, why intrinsic value should be so highly esteemed. In due course I visited Agra, not to see the Taj, but to extend my acquaintance with the exquisite sandstone work of the older period. I was familiar with the fine examples to be found at Ahmedabad, Puttan, Dabhoi, and elsewhere, and I continued to regard the Taj as a costly jewel, exhibiting in all its details the decline and not the zenith of Hindoo Saracenic art. I

surprised the guide I had engaged to take me about by the close attention I paid to the old red sandstone work, and my indifference to the costly gem which gleamed in the distance. After a few days, to the guide's great relief, I decided to visit the Taj. We arrived at the entrance mosque a little before noon. I was so struck with the beauty of its interior that I forgot all about the Taj, when, crossing one of the openings which commanded a full view of it, the sunlit building itself suddenly burst upon me—but that was surely not the Taj! It was not a building at all. But what was it? A painted scene? No. A model? Yes, it must be a model; the real building was doubtless out of sight. "What is that?" I asked the guide. "The Taj," he replied. I smiled incredulously. I was not to be taken in.

Perhaps some of my hearers may have observed a curious illusion which occurs at sea if a boat is approaching from a distance; the men who man the boat look like pigmies, and if nothing intervenes to express distance, and you watch continuously, the men remain pigmies until the cheated sense revolts, and the pigmies suddenly enlarge to full-sized men; to me personally, the illusion remains until the boat is quite close to the ship. Now in some such way I seemed to realise suddenly that what I took to be a model was a building of noble proportions, but this knowledge seemed to increase rather than to diminish the effect of mystery; it was truly, as my friend said, unlike anything I had ever seen—a translucent visionary object, part of the sunbathed atmosphere, all-satisfying in its loveliness. For awhile I stood gazing in the simple enjoyment of the scene, then, as the sense of keen pleasure gave place to a sense of curiosity, I determined not to move forward one step until I had solved, at all events in part, the secret of this almost unnatural effect, and how it came about. First, I observed that all the shadows were in a very high key; the lights on the dark foliage of the cypress trees were deeper than the deepest shadows on the building; again, the windows, which seemed at that distance simple frames, opened into comparatively light, not dark chambers, while the entrance doorway looked like an ink-blot, seeming to mar the general harmony. I felt convinced that this effect was not intended, and looked for other inharmonious notes. These I soon found in the deep shadows of the subordinate cupolas on the roof. As my eyes became more critical, I detected the comparative coldness of the shadows above the roof as compared with those below; the shade of the great dome was grey, while the shadows of the recesses were of a warm amber colour. Everything above the parapet seemed cold and lifeless, while everything below sparkled in the brilliant sunshine, suggesting tones of crimson, citron, green, and orange. Approaching the building, I found it to be in the centre of the large platform of white marble which cannot be seen from the entrance, but the roof, which was doubtless also intended to be of white marble, was covered with that dullest of all dull but useful materials, Portland cement—a deep-toned green-grey! The difference in the effect seems to justify the belief that the roof was intended to throw back on to the dome the maximum amount of reflected light, just as the marble platform on which the building stands throws back the maximum of reflected light on the lower part. You will observe that the face of this platform, viewed from the gateway, appears to be part of the building, an intentional illusion I believe, which adds to the general ethereal effect by the weakening of the shadows due to the distance between the foliage and the building. Examining the windows more closely, I found that the comparatively light appearance was due to a regular pattern of white marble which acted as a white veil and could not be perceived at a distance. As cost was no object I cannot help thinking that if the effect produced was not intentional, the windows would have been filled by elaborate arabesqueing like the screen at Delhi or the Ahmedabad Palm Window. Tracery of this kind would have had a much richer effect, but, of course, it would not have toned the openings to that delicate warm grey. I found also the intensely black spot (the entrance which really opened into the building) to be without a blind or chick, though the two metal rings intended to hold it were in the lintel of the door. Mr. Havell, in his essay on the Taj and its designers, published in the *Nineteenth Century and After*, says that this opening was originally closed by silver doors. If this is true the door-hangings are probably in the frames still; the rings for the hanging of the chicks satisfied me, and I am sorry I did not look further. Again, the four corners of the building are cut off to a considerable extent to avoid the depth produced by simultaneous contrast. Lastly, the effect which would have been produced by mouldings and sunk surfaces in this particular style is here produced by black marble inlay, so that the general appearance is not unlike lace, and at the first glance gives the effect more of a drawing than of a real building. It is difficult to imagine that the attempt to

secure the maximum of reflected light, the systematic heightening of all shadows on the façade and dome, the avoidance of strong contrasts, and the provision for planting heavy foliage around and before the building, were all the result of accident rather than the systematic working out of an artistic idea, and still more difficult to understand how, if that idea originated with the architect of the building, it was not carried out consistently to the finish, instead of being stopped at the point where, owing to the deep blue of the zenith, the strongest reflected light would be required. I do not intend by these remarks to disparage the architecture in any way. I am quite ready to admire the proportions, and to admit that the Taj would be a remarkable building under any light and constructed of any materials. What I desire to point out is that the startling ethereal appearance is not due to scholastic architecture, and could hardly have originated in an architecturally-trained intelligence, for such an intelligence is antagonistic to this principle of subordination, and delights in producing brilliant contrasts; it is rather an artistic thought, the idea of an artist, a man who loved light and could divide it into a hundred shades; a man who said to himself, "I have here practically an inexhaustible purse, the most lustrous material the world can produce, and the brilliance of a tropical sun. I will use my materials as I would paint a picture, subordinating all the deep shadows on the building, so that it will appear ponderous yet cloud-like, rising like a dream-palace out of a garden consisting of the deepest foliage procurable." The effect which the building produces on the observer leaves the artist's success beyond a doubt, for the man with the idea has portrayed materially the subtleties of pictorial values, which neither picture nor photograph can fix; in fact, he did for this style of art what Shakespeare did for the drama of his day, and the Taj will always be condemned or exalted in exact proportion to the perception of the idea.

In order to see clearly that this building was the natural outcome of the architecture of the period we must glance at its history.

The Moghul empire, commencing with Bābar in 1526, lasted till about 1707, a little less than 200 years, and during this period a broad belt of the country from Lahore to Agra came under its immediate sphere of influence. It must be borne in mind that when the Mohammedans conquered India they found in all parts of the country a perfected art of architecture and groups of skilled workmen who were freely employed in all directions, and the Mohammedan ideas which filtered through these workmen gave rise to that mixed form of art named by Mr. Fergusson Hindoo-Saracenic, and if the zeal and energy the Hindoos threw into their work is any indication of the state of their feelings, it is interesting to note the goodwill that seemed to exist between the two races. But there was another influence at work. The commercial relations with all the countries west of the Indus increased during this period, and in proportion as they increased the Hindoo element died out of the architecture, and, at the time the Taj was built, although the actual workmen were Hindoos the feeling and many of the forms were imported from the Bosphorus or Persia. We may conveniently divide the architecture of this period into three classes—first, the pure sandstone work; secondly, sandstone and marble mixed; and, thirdly, pure marble. In architecture the Hindoo disliked the arch as much as the Greek did; both seem to have felt instinctively that an arch always embodies the self-destructive element; an arch is, as it were, always "awake" and never for one moment forgets to exert a thrust. In pure Hindoo art openings are bridged by corbelling, and it is to the strict adherence to this principle that we owe the great sense of repose which their architecture conveys. I will show you the general evolution. [Worked out on the blackboard.]

Perhaps the most beautiful and intricate style of corbelling is to be found at Dabhoi in his Highness the Gaikwar's dominions; as it would take too long to work this out on the blackboard, I have sketched a slide. You see how each corbel supports a column, the column's support strings ending in another corbel, and the spaces between are strutted by panels on which deities are represented. The same hatred of thrust and cross-strain exhibits itself in their domes, which are of low curvature on the exterior. First, the corners were corbelled out to form an octagonal figure, then stone beams were laid alternately square and diagonal until the space was small enough for a single stone.

It is hardly necessary to point out that this style has its limitations; its halls of a thousand columns simply meant that the space required necessitated a thousand points of support. But with the Mohammedans came the demand for greater clear space and greater height, and the consequent introduction of the arch and the true dome. The Hindoo builder never assimilated the arch; indeed, when used as a constructive feature, its lines were ignored and its

decoration had no sympathy with the joints of the work. The arch would be constructed as an arch, but the lines of ornamentation accentuated panelling. It was not so, however, with the dome. From the first they seem to have grasped the fact that, unlike the arch, the self-destructive element is under control, that each ring of a dome properly tied in exerts no outward thrust; hence, under Mohammedan influence, the dome-builders of India attained a mastery over this form unknown and seemingly unappreciated by the builders of the Western world.

You will observe that if it is required to cover a square area by a dome, the section from corner to corner presents a very different aspect from that of the section parallel with the sides, as the corners are wholly unsupported. The methods adopted for supporting the superincumbent mass at the angles differ in different styles and different countries; perhaps the most beautiful and stable was that adopted generally by the Central India dome-builders. This method may be described as the intersection of two squares within the larger square in such a way as to leave a true octagon in the centre. This was further reduced by a figure of sixteen sides before passing to the round. An arch is then thrown from 1 to 2, 2 to 3, 3 to 4, and 4 to 1. Each of these arches is thus intersected in two points. The interior view is very beautiful. You may get a faint idea of what it looks like from the photograph of a Bijapur dome. If an embroidered cloth is thrown over the "eye" the interior effect is very beautiful, and the echo destroyed. A dome constructed of stone can be cramped and dowelled ring by ring, but when constructed of brick. the stability depends a good deal on the strength of the mortar. The great dome at Bijapur has cracked into lobes, and each lobe rests against its opposite neighbour in perfect equilibrium.

The dome of the Taj starts at once from the octagon, and is closed practically at the roof level, so that all work above the roof is merely for show. These domes seem to have been built without centres. Scaffolding and centring in India is formed of bamboos tied together with coir rope, and the form of the arch on the top is made up of brick laid in clay and brought to the correct form with that material. No centre of this description could stand continuous heavy rain. Consequently the size of a dome, if supported during construction on a centre of this kind, would be limited by the amount of work which could be done during the dry months of one year. At Golconda I noticed among the tombs that the last to be built had a very elongated appearance. Going inside to ascertain the cause, I found that it was not a true dome at all. The builders were evidently working on tradition; they had feebly turned in the top until their hearts failed them. Then they had boldly trussed the upper part and left the truss in.

You will understand, when I show you a specimen of the pure Hindoo-Saracenic in sandstone, how the introduction of the arch revolutionised the reposeful feeling of the art. Here is a view of the Muntapum on Jehangir's Mahal in the fort at Agra. Although it is called Jehangir's Mahal, Mr. Fergusson puts the date of its construction much earlier, and I quite agree with him. I also show you a view of the Bir Bul in the same pure style. The most beautiful specimen of the second group, where marble is freely mixed with sandstone, is the famous gateway of the mosque at Fatehpur Sikri. The highest architectural authorities, among whom I may mention Mr. Phené Spiers and Mr. James Fergusson, regard this gateway as one of the most perfect architectural achievements in the whole of India. You will observe here that the arch is the dominant form, and that every Hindoo detail is modified, more or less, to suit Mohammedan and even Western tastes. In the third, or entirely marble group, of which the Moti Musjid or Pearl Mosque is a good specimen, structural propriety has given place to extreme elegance. The little kiosks which formerly crowned an angle, a minaret or a spiral staircase, have become attenuated ornaments; the arches a series of cusps cut in an apparent solid: the columns, pieces of pannelled walling; the capitals and bases, mere strings; and the elaborately-consoled cornice, a plain curved feature. The carving generally is in that Byzantine style of art which was imported from the shores of the Bosphorus, doubtless modified as it journeyed eastwards through the countries west of the Indus.

This cursory glance at the architectural development which extended over three-quarters of a century shows that although the workmen always were, and indeed are now, mostly Hindoos, the style was gradually tempered by Western ideas, and that at the time the Taj was built the Hindoo spirit had almost passed away. The general arrangement of a central dome with four smaller domes at the angles is similar to that found in Humayun's tomb in old Delhi. Mr. Fergusson says of this tomb in his history of Indian architecture:—"Its plan is in fact that afterwards adopted at the Taj Mahal, but

used here without the depth and poetry of that celebrated building . . . It is so very unlike anything else that Akbar built that it is hardly possible it could have been designed by him. It has not even the picturesque boldness of the earlier Pathans' tombs, and, in fact, looks more like buildings a century at least more modern than it is." Now Humayun's tomb is said to have been commenced by Humayun's widow in 1530, and a century later brings us to Shah Jahan, the builder of the Taj.

In Fanshawe's "Delhi, Past and Present" Humayun's tomb is said to have been built by Akbar, commenced in 1556 and finished about 1569. A careful examination of the tomb itself, however, shows two distinct periods. The part first constructed by Akbar—the central dome and the façades—seems to have been overlaid at a much more recent date, while the part finished *last* by Akbar, the small domes and cupolas on the roof, have been allowed to remain as Akbar finished them. In order to bring out this fact more clearly I have made a sketch of the tomb as I think it was originally finished. Observe that the open parapet, which surmounted all buildings up to the end of Akbar's reign, has become a flat inlay of white marble on a plain piece of walling. It is a parapet no longer, but a pictorial inlay of white marble, actually turned down at the angles like a picture-frame, apparently to preserve continuity between the upper and lower cornices, an impropriety which, I feel certain, no architect of Akbar's period would have been guilty of. The great central dome has the drum corbelled out to support the overlay of white marble, which seems to have been spread all over the original work so thickly that it buries the usual floral centre and the metal finial up to the top of the lower member, and it is curious to note that the jointing of the marble is exactly similar to that adopted on the Taj, a broad and narrow course alternating. The two small domelets would end the façade in this style, the parapet, as in the Fatehpur Sikri gateway, ending at about the limit of the cornice, but the applied work is made to run out further and return the parapet vertically down, as I before mentioned, to meet and continue the parapet on the lower level. This overlay alters all the proportions of the façade, and I think it will be conceded, when due allowance is made for a very small imperfect sketch, that the restoration I have attempted is infinitely more like the spirit of Akbar's work than the photograph of the building as it is. A careful examination of the building itself would set these conjectures at rest. The matter is of little importance now, were it not that this building furnished the plan and general arrangements of the Taj, and the two buildings have this remarkable affinity: *both* exhibit *two* distinct periods in the principal features, the façade and the central dome being of one period, and the small domes of another. In Humayun's tomb the older visible parts, the four small domes—naturally the last parts to have been constructed—are much earlier in style than the main dome and façade, the first parts to have been finished; the four small domes on the Taj, also the *last* part to have been constructed, likewise show an earlier date, or, at all events, a return to what would be considered an older form of art.

I am afraid this is a little confusing, but I can make my meaning clearer by taking refuge in conjecture. It is as if the man with the idea had been allowed to experiment with white marble in Shah Jahan's time on Humayun's tomb, and that while he worked, the idea of the Táj grew and became perfected; that he worked only on those features which he intended the Taj to possess—the great dome and the façade. That a successor, knowing Humayun's tomb to be his source of inspiration, but not understanding the principle on which his predecessor worked, constructed the four smaller domes and the lighthouse-looking minarets at the angles of the platform after the man with the idea left. The building would not suffer, in my opinion, if these small domes were removed; as I have pointed out, they serve no useful purpose whatever; the outline would gain in simplicity and the roof, if covered with white marble, would make the great dome a more ethereal object than it is now. In that water-colour drawing you will see what I conceive to have been the intention of the man with the idea, and although no drawing can convey the effect of the building, a comparison with the photographs of the building reveals to my mind no sense of lack of, but a distinct gain in, simplicity and repose.

I have endeavoured to show by this somewhat prosaic dissection that the unique appearance of the Taj Mahal arises from a studied and systematic system of heightening the deep shadows and avoiding all those black patches which destroy a sense of distance. I have endeavoured to show you that its architectural lines were the natural outcome of the styles which preceded it, and that the foreign influence is no stronger in this building than in other works constructed during this period; that the startling effect of the Taj is due to the studied control of light and

shadow to produce what one might almost term a scenic effect in opposition to that produced by ordinary architectural practice, and I also think this effect largely dependent on the extent and quality of the foliage in the surrounding garden, and that the first glimpse of the building should always be from the entrance gateway with the sun or the moon in the zenith. That this effect is in the majority of cases unexpected and startling is beyond question.

Dr. Leitner, in this room not many years ago, speaking of the Taj, compared it to a piece of lacework. "It appeared," said he, "with its dark background of foliage to float in the air, it was more like a dream than a reality." Bishop Heber said it was the conception of giants carried out by goldsmiths. The late Sir W. W. Hunter described it to me as "a stupendous jewel—not a building at all!" But perhaps the best description is that given by Sir Frederick Treves, one of the most recent travellers. "Everyone," he says, "who visits Argamand Banu's tomb for the first time approaches it with curiosity, tinged probably by a faint disposition to be hostile. So much has been written about this wonderful building, so much rhapsody has been lavished upon it that there is some suspicion of over-praise. The claim that it is the most beautiful building in the world is a claim that many at once resent. Its outlines are familiar enough from pictures and models, and it may be that they hardly warrant unrestricted ecstasy. The visitor proposes to himself to put sentiment aside and review the building critically . . . to submit it to a common-sense inspection, for he is inclined to believe the Taj Mahal to be a much overrated monument. He has, indeed, already imagined himself on his return home giving to his friends evidence of his originality by asserting that as for the Taj he sees nothing in it . . . With the first sight of the Taj Mahal there comes only a sense of indefinable pleasure, it is no mere feeling of admiration, still less of amazement. No mere delight in a splendid building, because it does not impress one as a building. There is a sudden vision, and with it a sudden sense of ineffable satisfaction, as if in the place of a marble dome the garden had been filled with divine music. All intended criticism is forgotten; there is nothing that appeals to the judgment or that suggests the weighing of opinions. There is merely a something that touches the finest sense of what is tender, beautiful, and lovable—a white cloud, luminous, intangible, translucent! The secret of the beauty of the Taj Mahal lies in the great arched recesses or vaulted alcoves which burrow deep into the body of the building. These are throbbing with sensitive shadows, and they give the impression that the onlooker can see into the very heart of this gentle palace as one would gaze into the heart of a yellow rose, where leaf by leaf the tints become deeper, warmer and more living. There is ever a sense of something half hidden and half revealed of a tenderness which has deeper depths! . . . It is this abiding suggestion which makes the peculiar glory of the Taj a glory which is beyond the reach of any picture or any model. To many the Taj will be the most beautiful building in the world, while there must be few who would not acknowledge that it is the most loveable monument that has ever been erected." If architecture compared with mere building is really the compensation which man offers to his fellows for robbing them of so much of God's fair work as each building blots out, the sins of the man who inspires such praise as this, must surely be forgiven. Who the man was matters very little; indeed, for all that, it might have been a woman! But whoever it was, receives the gratitude of countless admirers.

It seems to me that a paper like this, though dealing however slightly with one of the most glorious periods of Indian art introduced by a conquering race, would hardly be complete without some allusion to ourselves as the present ruling power. Englishmen are ever ready to point out the shortcomings of their own brothers and sisters, and I have heard most unfavourable comments made about the awful mess we have made generally with the arts in India. I think perhaps as regards the industrial arts a true bill may be found against us, and yet even here, the natives of India themselves have been the greatest sinners. We tempted them with commercialism, it is true, but they showed no disposition to avoid the diet, and a walk through the wealthier quarters of the principal cities will show that many of them gorged themselves. A large and earnest band of ladies and gentlemen have devoted themselves to the problem of conserving the native industrial arts of India, and the Government have always been ready to assist them in every way, but the questions—what is there to conserve? where is it to be found? and how can it be conserved? are not easily answered. When, however, we turn from this to a more extended view, and see the railways, roads, canals, irrigation works, lighthouses, bridges, and other public works which our

fifty years' rule have given to the country, we may rest contented that we have done more for the general advancement of the brotherhood of man, than if we had built a palace in every city, and a Taj in every talook.

When we narrow the field of view to architecture alone, the real scope of this paper, I trust I can show you specimens of art constructed during the past fifty years of which no country need be ashamed, and these are by no means the best specimens of architecture to be found, but the best specimens of which I could obtain photographs. Before showing you these, however, I must, in justice to the Indian workmen, explain that the labour procurable is of a highly intelligent order. In the 'sixties I set some ordinary stonemasons to design and execute granite capitals. I merely gave each a block of granite about 4-foot cube, with instructions to work from a square abacus to a round column. By the kindness and courtesy of Sir Arthur Lawley I am enabled to show you these three specimens of the result.

Individually we may differ as to the direction in which the art of architecture should move. We may think the issue of standard designs a little overdone; that a country covering twenty degrees of latitude, with seacoast, table-lands, and altitudes attaining twelve or fourteen thousand feet, demand a closer study of local conditions; we may regret that medical laws—chiefly made in Germany—may have restricted the output of hospitals, schools, and asylums, but when we look at the actual results of our fifty years' rule, I think, when you see the types of only a few specimens, you will agree with me that we have every reason to congratulate ourselves.

[Here the author showed a series of slides illustrating buildings erected in India during the past fifty years.]

In conclusion, I should like to offer some remarks on the future of Anglo-Indian art in India, but—and this is a great, great but—architecture in India, and, indeed, throughout the world, is entering on an entirely new phase, for that great potentate, ferro-concrete, has been enthroned, and his reign will be a long one. I am a great believer in the unity of ideas. The human body is composed chiefly of bones, flesh, and skin. If we put for these materials, steel, concrete, and porcelain, we would seem to have arrived at the ultimate of all sound durable construction, but the adornment of such a combination is infinite, and will demand the exercise of a new sense of fitness. In what directions the ferro-concrete art will be developed, it is impossible to say. I believe myself we are on the eve of a much more beautiful form of permanent building than the world has yet seen, for the capabilities of the new material seem absolutely inexhaustible—limitless.

DISCUSSION.

The CHAIRMAN remarked that no country in the world lent itself so generously to good architecture as India. In its varied scenery of stupendous mountains, far-reaching sun-lit plains, deep forest gloom, valleys, some clothed with bright crops, others buried in the seclusion of rocks and trees, placid, broad rolling streams, cascades and surging torrents, the builder could find every setting he desired to express his temper and moral feeling in devotional or memorial work. Nature was equally lavish in every accessory, while for many months a cloudless sky showed to the best advantage the work of man. Some beasts of the forest such as elephants were models of strength, while others as the deer and antelopes were models of delicacy and gentleness. Vegetation offered the sculptor a wealth of beauty in the bamboo clump, the lilies that lay on the laps of lakes and pools, or the orchids which draped the trees in the jungle. Ferns of every size and texture, and flowers of varied hue carpeted the ground, while in strength and luxuriance of foliage the teak and the mango respectively could not be rivalled. For suggestions of colour where could such sunsets, rainbow tints, or frowning tempests be witnessed as those of India? The birds of the air built nests of every subtlety of protection and grace of construction. With all these models, the national character, if one might ever apply so generic a phrase to anything in India, gave a particular impulse and direction to her architecture. Centuries of civil war and invasions, and the selfish neglect of her rulers, previous to the establishment of British rule, in failing to offer any resistance to famine, floods, disease, or other natural enemies of mankind, had ingrained in the peoples of India a sense of resignation, patience, self-denial, and a feeling of the irresistible omnipotence of God. Perhaps the same cause accounted for too ready an acquiescence in deception and unreality which affected both the choice of material and the execution of design, and, as the Chief Engineer in Mysore had lately remarked, introduced a slackness into the work of the builders. No doubt national sufferings as well as the enervating climate were opposed to the development of strength and the impulse to action which so characterised the Norman. But the spirit of religion, sometimes, it must be confessed, degenerating into superstition, moved on the face of Indian society, and shed its light and inspiration upon the whole field of architecture, Dravidian, Hindu, and Mohammedan. For building material Nature had supplied the wants of the

Indian with no niggardly hand in the Porbandar granite, the rich red sandstone, marble, and glittering agates, gems and jasper.

It must be confessed that in domestic architecture the conditions of Indian life had offered an easy option, and encouraged a low standard of comfort. Another influence in the same direction was the want of a sense of the dignity of human life. The masses of the people dwelt in the most squalid hovels, and even the well-to-do gentry lived in ill-ventilated, untidy premises, without a thought for sanitary conditions or pleasing effect. When the State built lines for its soldiers, police, or the numerous dependents of a ruling chief, little regard was paid to reasonable comfort and none to architectural effect. The palaces of the Rajas themselves, with few exceptions, displayed no taste, and supplied none of the adornments or comforts which natural pride of high position and public opinion demanded in European countries.

It was in its devotional and monumental work and not in domestic architecture that the heart of India was touched, and made a serious endeavour to express its ideals in stone. And as the Hindu religion differed fundamentally from the Mohammedan, the difference asserted itself in their temples and monuments, just as it did in their customs and habits of life. The Hindu character exhibited itself in exuberant fancy, patient if mechanical labour, and meticulous detail, too often losing touch with the central idea which the architect intended to express. Fergusson constantly repeats his criticism of the Tiruvalur Temple near Madras, in his descriptions of other Hindu buildings: "We may be astonished at the elaboration and evidence of labour, but as an architectural design it is altogether detestable." Even the ordinary sightseer could not help being bewildered at the majority of Hindu temples. If you look at a Norman building you realise strength, or at a revivalist cathedral beauty, or at a Greek Parthenon wisdom. In the Hindu temple the details distract your attention, and frequently you cannot see the forest for the trees. You can form no idea of what the architect intended. There is no central idea, no harmony, and no self-control. There is not even a dedication of the work to a single one of the great Hindu gods, neither unity of worship nor unity of design. The parts are overloaded with numerous idols, and where Nature has been drawn on to supply the models, the most incongruous beasts, birds, and vegetation have been thrown together in a mass—*e.g.*, elephants borne aloft on the heads of puny men, pouring from their trunks streams of water on the divinity seated on a lotus.

Mohammedan architecture speaks with a more certain sound, proclaiming the unity of God, banishing all likeness of man or creature from the surface of the stone, subordinating all details to the central idea, and laying at the feet of the departed soul or of the Creator the grandest tribute which heart, hand, and eye can conceive and execute. In this respect the Taj Mahal stands supreme. This grand triumph of the architect's art was still building when the drowning of his friend King, in crossing the sea from Chester to Ireland, inspired and moved Milton to pour out his soul in Lycidas. The inimitable hand which built the monument in stone to the Mumtaz Mahal (exalted of the palace), wife of the Emperor Shah Jahan, was not less poetical than the master of melody, John Milton, while the work of the former is free from the incongruities marshalled together as fellow-mourners in Lycidas. All the thoughts which can comfort the human soul in the presence of conquering death are expressed on the buildings on the bank of the Jumna, which rise in silence a mile and a half distant from the clang and pomp of the busy fortress of Agra—rest, hope, beauty, and eternity. Mr. Chisholm, from the architect's knowledge, had told them how material and construction lend peace and rest to the great mausoleum with its softened light. The environment heightens the effect of the builder's art. The numerous uplifted pinnacles, as well as the dome pointing heavenwards, tell us of assured hope. Beauty is expressed not merely in every detail, but stamped on the whole design and its execution, the parts being subordinated to the whole, the decoration exquisite and yet subdued and controlled; while the solidity of the material and the pure marble platform, with the stream flowing by in its ceaseless course, until time shall be no more, remind the spectator of eternity. Night succeeds day, and the lamps of heaven flash with softened light on the waters of the Jumna, and still the beauty of the monument is not impaired; nay, it is rather increased by the starry firmament and silver sky. Truly, one feels with Shelley—whose tribute to Keats in his "Adonais" is the most beautiful monument in British verse—as one thinks of the emperor's wife resting peacefully beneath the dome—

> "She is a portion of the loveliness,
> Which once she made more lovely."

Or, again, that the soul of the Mumtaz Mahal, as

> "The soul of Adonais like a star
> Beacons from the abode where the eternals are."

Happily, the Taj does not speak only to the architect, nor only to the Mohammedan. It appeals straight to the heart of all who see it, as no other building in the world appeals; and Indian architecture has enriched the inhabited universe, and proved that the highest ideals and dreams of human genius can be expressed in stone as well as verse. The thanks of the Society were due to Mr. Chisholm for helping them to realise why the Taj exercised so potent an influence on all who beheld it.

Sir George Birdwood said:—I feel I must take a part in the discussion, having joined Sir William Lee-Warner in insisting on Mr. Chisholm favouring the Indian Section of the Royal Society of Arts with

the paper that has held our gratified and grateful attention during the past hour. Mr. Chisholm is an architect of marked ability and skill; and of extensive knowledge, at first hand, of the historical building styles of India, combined with an exceptional insight of the merits of Indian art, and an enthusiasm for it as sane and discriminant as it is spontaneous and stimulating; and those among us who know Mr. Chisholm personally well foreknew how completely he would carry the present meeting with him in his clear and convincing technical descriptions of the material features of the so-called Taj Mahal, and his subtle analysis of the sources in those features of something of its irresistible and incontestable charm for all whose eyes have once been quickened by the pure and faultless apparition of it to a true and, for many of us, a passionate sense of its incomparable spiritual beauty.

But I hesitate to speak on an architectural subject, for not only is architecture a department of fine art but of high applied science also, and, alike as fine art and civil engineering, it is entirely beyond the range of my responsible criticisms, limited as they are to the subjects of applied art, that is the arts and crafts, otherwise the industrial arts. To express this in a metaphor,—I dare not look up into the face of "the blue-eyed Maid," and only bow down myself humbly to the fair latchet of the straps of her sandals; and all my life long my responsible interest in the so-called Taj Mahal has been in its mosaics and other decorative details.

But before I pass to these, let me say in explanation of the point of view from which I approach such questions, that, in my opinion, what we differentiate as Saracenic art has really little to do with the Saracens. None of the Semitic races ever invented a building style that could be classed as architecture, *i.e.*, architecture regarded as a fine art; and no tribe of pure Arabs has ever shown inventive ability even in the practice of the applied arts. The Assyrians and the Babylonians, like the other Semitic races, betray a keen appreciation of the sumptuary applied arts, in their clothing and jewellery, their furniture and the embellishment of their palaces, their armour and horse trappings, and chariots, etc. But their building style never rises beyond civil engineering; and it is almost certain that their applied arts were derived from the aboriginal Turanian populations of Anterior Asia, such as the Akkads and Hittites, peoples apparently allied to the Chinese and Japanese. Passing to the Jews, we know that the so-called "City of David"—really a fortress—and "Solomon's Temple," and the Palaces of David and Solomon, and "the House that is in Lebanon," were all built, and decorated, and furnished throughout, by carpenters and masons, and other handicraftsmen sent down to King David and his son Solomon, by Hiram, King of Tyre, expressly for the purpose of erecting these buildings; all of which is set out and in great detail in the Biblical "Books of Samuel," and "Books of Kings": and these handicraftsmen were all mongrel Turanians, cognate with the Hittites of Syria and the Akkadians of Mesopotamia [*cf.* 1 Chron. iv. 14, "the valley of (Çanaanite) craftsmen"]; this going far to explain why the restorations of "the House that is in Lebanon," given by scholarly and learned European architects, so closely recall the photographs shown here last year by Mr. J. Claude White of the alpine palaces, fortresses, and monasteries of Bhutan and Sikkim, and Thibet. As for the Saracens, they never of their own initiative raised a single building that could be called architectural. Their *Kaaba* itself, the cynosure of pan-Islam, was built by a Greek, and its very name is Greek, *κύβος*, "a cube." To this day all the so-called "arabesque" embroideries produced in Egypt are the work of Greeks [*cf.* Acts xix. 24, Demetrius, "a silversmith," and 2 Timothy ii. 14, Alexander "the coppersmith"]. The fact is, the Saracens wherever they went on their ever-victorious way, like the Assyrians and Babylonians before them [*cf.* 2 Kings xiv. 16, Jeremiah xxiv. 1], kidnapped and employed the local handicraftsmen of the countries they subdued to do all their artistic work for them, in architecture, furniture, clothing, armoury, etc. These were Greeks, or Hellenised Egyptians, Syrians, and Persians [Aryans, like the Greeks themselves]; only these Greeks had to adopt their designs to the uses, the manners and customs, and above all to the rigorously monotheistic religious prejudices of their Muslim conquerors. It was in this way that the Byzantine art of Northern Africa and Anterior Asia was gradually transformed into what we call "Saracenic Art": its first, full, and felicitous inflorescence being seen in the "mosque" of Old Cairo; and later in the "mosque," now the Cathedral of Cordova; and later still in the Cathedral of St. Sophia, now the great "mosque" of Constantinople. Similarly, the Islamite Pathans, Mongols, etc., on subjugating Hindustan and the Dakhan, largely employed alike Persians and Hindus in the construction of the palaces and tombs requisitioned by them; and so sprung up all over India such types of Indo-Saracenic art as the *Masjid** at Peshawur, the columns of it reproducing those of the Mosque of St. Sophia; the Pathan tombs of Old Delhi; and the Moti *Masjid* of Delhi; the *Masjid* at Mandu in Malwa; the *Jami Masjid* at Bijapur; and the *Musalla*† a "small" *masjid* at Golconda.

Going into details, the "Taj Mahal" of Anglo-Indians is quite wrongly so called. *Taj* means a diadem, the comb of a cock, and *mahal*, an abode, a seraglio, a district, and *taj mahal*, a royal

* The word *masjid* means "place of prostration," *i.e.*, "of prayer," and in the mouth of the Spaniards became *mezquita*, and of the neighbouring French *mosquée*, and in English mouths, across the Channel, "mosk," and later "mosque."

† *Musalla* refers to the "small" mats, or carpets, used by Muslims as a "prie Dieu." The other terms for these small mats are *sajjahda*, meaning place of "prostration," and *jai namaz*, "place of prayer."

kingdom, a queen, etc. But here, as the European designation of the sepulchre of the dearly-beloved and loving Queen of the Mo(n)gol Emperor Shah Jahan, Argamand Banu Begum, it is simply the clipped and corrupted Anglo-Indian form of her imperial title of Mumtaz Mahal. As to the perplexed question of the "Taj Mahal" being a building, the consideration to bear in mind is that it is not a palace, nor place of habitation of any sort, but simply a *tabut*,* or "coffin" on its catafalqued bier, and "a tomb," a sepulchered—*i.e.*, an "honoured" tomb, and a Mausoleum, or magnificent "tomb," enclosing its two sarcophagi and two cenotaphs under one dome. Its type is to be found in the *taziahs* [literally, "consolations"], or model catafalques representing the tombs of Hasan and Husain at Karbela, carried by the Shiah Muslims of India and Persia in the solemnial procession of the Muharram. If this is kept in view, the airy, fairy lightness, and elegance, and sweet, and winsome grace of the "Taj Mahal," become, in my opinion, less inexplicable, if we must insist in penetrating into the magistery of its fascinations.

As to the cypress trees enshrouding it, I believe they were planted long after the date of Shah Jahan, and that the platform of the Taj was originally laid out with perennially flowering beds of the "African marigold." The complementary flush on the white marble building from them, under a clear blue sky, would have been a delicate terra-cotta pink; and may not that have been what Shah Jahan, or his sympathetic architect, precisely intended? The scarlet geraniums that now carpet the garden are in execrable "post-impressionist" taste, and must reflect a faint purplish grey from the building. I think there is true artistic insight in Mr. Havell's suggestion that any door that may have once been placed in the entrance to the Taj must have been of silver. But I cannot recall an actual closing door at the entrance to any Moslem *tabut* in India.

Of the more effective features of "The Taj" are its minarets, among the loveliest in all Islam; and the minaret is the one original feature the Saracens contributed to architecture; and it would be worth enquiring into its origins—in "the highest heaven of invention"! In spirituality of effect it equals the Christian spire; and both possibly originated in the instinct alike of Christendom and Islam to raise man up into the heaven of heavens, as opposed to the Heathen instinct—and I often feel the happier instinct—of bringing the high gods down into the common daily life of mankind. Then as to the concrete laid on the roof below the dome; it is a dreadful solecism; and I can hardly believe it to have been put there by Shah Jahan, or his inspired architect: and could it not be over flagged with Jeypore marble?

Lastly—of such details—I have always believed that the peaceful and consoling impression produced on its beholders by the "Taj Mahal," is not only due to the exceeding beauty and comeliness of its architecture, that at a glance satisfies your artistic sensibilities, and presents nothing to irritate and condemn, but in part also,—at least in the deep religious feeling it engenders,—to the touching associations of its conception, and the purpose it serves, as an everlasting memorial of the undying devotion of Shah Jahan and the Mumtaz Mahal to each other. Nothing outlasts to the end of the record of humanity but its pathos; and in all history there are no human instances more pathetic than the scene and circumstances of the death-bed of the great Akbar, and the love of Shah Jahan and the Mumtaz Mahal for one another, and his consummate commemoration of their ineffaceable affection. He was absolutely faithful to her for the twenty years of their unclouded and unsullied married life; she bore him the while nearly a score of children; and he remained faithful to her memory all the years he survived her; and the splendid and enchanting tomb wherein, to the awed awakening of the last trumpet, he sleeps beside her, took twenty years to complete and perfect to something of the measure of his measureless passion for her. That I believe to be the inmost secret in every manly and womanly heart of the enigmatic, incommunicable magic of the Mausoleum of the peerless Argamand Banu Begum, the Mumtaz Mahal, and her "blameless Polixenes," the magnificent minded Shah Jahan. Our unbounded thanks are due to Mr. Chisholm for the simple, lucid, and sympathetic manner in which he has demonstrated to us the fine artistry of the shrine that embalms both their fragrant hearts as in one and the same exquisite and enduring reliquary:—"An eternal [architectural] excellency, and a [spiritual and æsthetic] joy for evermore."

Sir STEUART COLVIN BAYLEY, G.C.S.I., said the only excuse he had for addressing the meeting was that he was an old friend of Mr. Chisholm. It was just about half a century ago that he first made the author's acquaintance at Patna, when he, being a Philistine, had not the least perception of the distinction and honourable position to which Mr. Chisholm would attain. They were both young in those days, and used to laugh—occasionally to laugh at their seniors—and although he would not say that Mr. Chisholm was irreverent, he had just that touch of irreverence which made for originality in an artist, and which enabled him to see for himself and teach others to see without consulting the books. That touch of originality could be seen not only in the paper but throughout all Mr. Chisholm's works on the Taj. He was not content with what others saw in the Taj. He must examine for himself, and having seen its glamour he must discover the secret of it, the character of its divergence from other Mogul architecture. What he (the speaker) thought the audience had to thank the author for most was the explanation he had given of the Taj. Hitherto they had always worshipped

* This is the same word as the Hebrew *tebah*, "ark," as applied (Exodus ii. 3) to Noah's Ark.

the Taj as an unknown god, but Mr. Chisholm had now given a reason for their faith. Up to the present time the Taj had always been spoken of as "A dream in marble"; Mr. Chisholm had shown that the dream came through the ivory gate. Shakespeare wrote that Queen Mab was the propounder of dreams. Evidently Mr. Chisholm had had Queen Mab to explain the Taj to him, and he had put that explanation into the paper. He (Sir Steuart Bayley) was sure he spoke for all present when he said, they were immensely indebted to Mr. Chisholm not only for the trouble and skill which he had taken in preparing the paper, but for enabling them to understand it.

On the motion of the CHAIRMAN, a vote of thanks was accorded to Mr. Chisholm, and the meeting terminated.

Mr. E. B. HAVELL writes:—Mr. Chisholm's paper raises so many points and contains so many ingenious suggestions that it is difficult to deal with it within a reasonable compass. I am glad, in the first place, that he has not attempted to revive the old Anglo-Indian legend that the Taj was designed by an Italian adventurer at Shah Jahan's court. That superstition takes a long time in dying, but some day, when it is decently buried, I hope we shall give it a monument in ferro-concrete as beautiful as that which Indian architects raised to Argamand Begum.

Mr. Chisholm seems to suffer from a conflict between his artistic feeling and his architectural conscience. As an artist he is constrained to admire the Taj with a whole heart; as an architect he is inclined to damn it with faint praise. I confess I am no more able to understand Mr. Chisholm's distinction between art and architecture than I can appreciate Sir George Birdwood's distinction between "fine" art and "decorative" art. The designer of the Taj was no doubt a great artist, but I cannot agree that he was lacking in architectural intelligence because he did not aim at producing the brilliant contrasts of ordinary architectural convention. The Taj was not an ordinary building with a utilitarian purpose; it was a monument to a beautiful woman and an architectural symbol of womanly beauty. All Mogul art, down to the time of Burangzih, was inspired by Hindu idealism, and I have not the least doubt that the designers of the Taj meant the main building to represent Argamand Begum herself, and the garden in which it was placed to be the Garden of Paradise, according to the beautiful symbolism often seen in Persian carpets and painting.

I fully agree with Mr. Chisholm that, in the present condition of the Taj and its surroundings, there is some jarring note which conflicts with the harmonious intention of the original plan, but I do not think that he has indicated the right way of resolving the discord. Looking at the section of the main building, and the limited area of the roof, it would be easy to prove mathematically that the substitution of the original marble for the present Portland cement would have no appreciable effect on the shadows of the domes, as seen from below; and, looking at the plan, I am at a loss to understand why Mr. Chisholm should think that the four smaller domes, or kiosks, surmounting the four small chambers, or chapels, at the angles of the building, and the four minarets at the corners of the platform, are not part of the original design. I fail to find the disharmony he points out, either in the smaller domes or in the minarets; probably Mr. Chisholm would not wish to be taken seriously in suggesting their removal. We might have an agitation started in India for the removal of the cupolas of St. Paul's Cathedral or the towers of York Minster.

The discord which exists at present is not, I think, to be found in any part of the building, but in the surroundings of it. The original formal garden, planned in accordance with Persian and Indian ideas, was an integral part of one great design, and when it was remodelled according to the ideas of an English landscape gardener, totally ignorant of Eastern symbolism, we seriously marred the artistic unity of the whole original conception, and produced a disharmony, or want of co-ordination in different parts of the architectural composition, by blocking out with great masses of heavy foliage different parts essentially related to one another. Recently an attempt has been made to improve the garden in this respect, but not, I think, with much success; in fact, the wrong alignment chosen for the cypress trees will, before many years, cause a serious disfigurement to the main view of the Taj itself, as I tried to show in an article I contributed to *House and Garden*, in April 1905. If we could conceive a formal garden on its original lines, as perfect in art and beautiful in symbolism as an old Persian carpet, spread out in front of the monument, we should still see the Taj Mahal as fair and flawless as its creators made it.

CANTOR LECTURES.

INDUSTRIAL PYROMETRY.

By CHARLES R. DARLING, A.R.C.Sc.I., F.I.C.

Lecture III.—Delivered December 5th, 1910.

RESISTANCE PYROMETERS.

When a wire composed of a single metal is heated, the resistance offered to the passage of a current of electricity is increased; and this augmentation of resistance continues as the temperature rises. Certain alloys, however, are practically unchanged in their resistance when heated; and some actually show a diminution, a property shared by carbon, which permits the electric current to pass more freely when hot than when cold. To demonstrate this point experimentally, we have

here a piece of iron wire coupled up with two cells and an ammeter, which measures the current passing through the circuit. On placing a burner beneath the wire, a large diminution in the current is indicated by the ammeter; but on removing the flame, and allowing the wire to cool, the current is restored to its former value. If, instead of iron, I use a piece of constantan (a copper-nickel alloy), heating makes little difference to the current; whilst with carbon the current is observed to increase. We thus gather that the greatest increase in resistance is manifested by pure metals, and this will guide us in applying the phenomenon to the measurement of high temperatures.

The first pyrometer based on this property of pure metals was devised by Sir W. Siemens in 1871. The metal used was platinum; and we may here note that all the exacting properties demanded of the metals used in a thermo-electric pyrometer for high temperatures, and fulfilled by platinum and allied metals, are in this instance of even greater importance. For, whereas the stretching of the wires, causing a diminution in diameter, would not affect a thermal junction, the resistance of the wire would be seriously altered, varying, as it does, inversely as the area of cross-section. The same remarks apply to thinning caused by oxidation or corrosion; and no good result can be secured unless the metal used remains completely unchanged in internal physical structure and external dimensions. No ordinary metal will fulfil these conditions above a red heat except platinum, which, chosen by Siemens, has remained ever since the only metal used in resistance pyrometers. In order to measure the resistance when in use, Siemens employed a device in which the current from a battery divided through a standard resistance and a voltameter on one side, and the pyrometer and another voltameter on the other. The current in each branch was determined from the quantity of gas liberated in the attached voltameter; and as the resistance in each section would vary inversely as the current, the resistance of the pyrometer could be determined. This method, although highly ingenious, was far too complicated ever to be welcomed in the workshop, and was replaced by a method of resistance measurement involving the use of a differential galvanometer. The principle of this method will be understood by reference to the diagram. A current from a battery B is divided into two branches, one containing the adjustable resistance R and one coil of the galvanometer, and the other the pyrometer P and the reverse coil. The galvanometer is wound so that both coils have an equal resistance, and with equal current exert the same pull on the magnet, but in opposite directions. When the current preponderates in one of the branches, the needle will move; but when equality is established in both circuits the needle will remain at rest. This condition is attained by adjusting R, and as equality of current in each half of the circuit indicates that each possesses the same resistance, R will then be equal to P. With the instrument thus made by Siemens, a table was provided from which the temperature could be read off; the value for known resistances given in the table having been determined by comparison with the gas scale. Some of these pyrometers are still in use.

The most concise method of measuring resistances, however, is furnished by the arrangement known as Wheatstone's bridge. In the diagram, B is a battery, G a sensitive galvanometer, *a* and *b* are fixed, known resistances, *d* is an adjustable resistance, and *x* the unknown. When *d* is varied until no deflection is shown by the galvanometer, the resistances in the four arms are so related that $\frac{a}{b} = \frac{x}{d}$, from which the value of x is readily obtained. When this method is applied to pyrometers, it is customary to make *a* equal to *b*, when *x*—in this case the pyrometer—has a resistance equal to *d*. This method of measurement was adopted in the later forms of Siemens' pyrometers, and is now generally employed by other makers.

The earlier form of Siemens' pyrometer consisted of a coil of platinum wound on porcelain, encased in an iron tube as a protection from the furnace gases. It was found, after a time, that the platinum had undergone a considerable change, the zero resistance rising 15 per cent. after repeated heating and cooling. This result was sufficient to discredit the method from an industrial standpoint, and for some years no further progress was made. Finally, however, the firm of Siemens and Co. largely overcame this difficulty by winding the platinum on a rod of special fireclay, and packing the space between the wire and the outer case with magnesia; the trouble having been caused, in the main, by furnace gases which penetrated the hot iron sheath and altered the physical character of the platinum so as to affect its resistance; which alteration is prevented by the presence of the magnesia. The Siemens resistance pyrometer is still made in this form.

The present success of the resistance pyrometer, however, is largely due to the researches of Callendar and Griffiths, who proved that under proper conditions the instrument could be made to give concordant readings, and was susceptible of a far greater degree of accuracy than the thermo-electric method. By careful comparison with the gas scale, these observers proved that the relation between the resistance of platinum and its temperature could be expressed by a formula which, over a wide range, would not lead to a greater error than $\frac{1}{10}°$ C.

Before proceeding to discuss this formula and its application, we will consider the possibilities of the resistance method with respect to the limits of accuracy. It is found, by experiment, that a piece of platinum wire which has a resistance of 2·6 ohms at 0° C., rises to the value 3·6 ohms at 100° C., an increase of 1 ohm. Assuming this increase to be uniform, the rise per degree is 0·01 ohm. Now this quantity is easily measured by the Wheatstone bridge method, using instruments that are suited to a workshop; hence a difference of 1° C. may be detected. With a larger battery power, and a more sensitive galvanometer, 0·001 ohm can be measured, corresponding, in the instance given, to a rise of $\frac{1}{10}°$ C. I illustrate this sensitiveness by accurately counterpoising on this electric balance—as Wheatstone's bridge is sometimes termed—a piece of platinum wire. When the spot of light is at rest the resistance is correctly adjusted; and now, by simply breathing on the wire, its resistance is sufficiently altered to send the spot of light flying along the scale. There is no single thermal junction which, when breathed upon, will give such a tangible result, and the great point in favour of the resistance method—that of greater delicacy—is thus conspicuously shown.

I have just made the assumption that the increase in the resistance of platinum is uniform, and that if we commence with 2·6 ohms every degree rise in temperature would add $\frac{1}{100}$ of an ohm. If this were correct, 4·6 ohms would correspond to 200° C.; 10·6 ohms to 800° C.; and so on. But when we test this matter by reference to our accepted standard, the gas scale, we find that the assumption is erroneous. We have been trusting the thin ice of extrapolation, and, as usual, the confidence has been misplaced. The work of Callendar and Griffiths, however, has shown that a definite relation exists between the values we have just assumed and the correct temperatures on the gas scale, so that by the aid of a formula the one may be converted into the other. If we indicate by p_t the degrees calculated on the assumption of uniform increase of resistance, and by t the true temperature on the gas scale, the relation between them is expressed by the formula

$$t - p_t = \delta \left\{ \left(\frac{t}{100} \right)^2 - \frac{t}{100} \right\},$$

where δ is a constant depending on the purity of the platinum, and generally has a value about 1·5. By inserting values in this formula, a table may be prepared from which the true temperature represented by the values calculated from resistance measurements may be read off. A few comparative numbers, calculated from this formula, are given in the table, the value of δ being 1·5:—

Temperatures calculated by assuming uniform increase of resistance.	True temperatures on gas scale (Deg. C.).
200	203·1
300	309·8
500	534·9
700	779·4
900	1049·4
1100	1355·0

It will be noticed that the difference between the readings increases rapidly as the temperature rises, and amounts to 255° at a true or gas scale temperature of 1355° C.

Having thus arrived at an accurate method of calibration, we may now proceed to examine the practical forms of instruments used at the present time. In the resistance pyrometers made by the Cambridge Scientific Instrument Company, the platinum wire is wound on a mica frame, and is connected by leads to a pair of terminals at the head. As these leads would alter in resistance on heating, a pair of exactly similar leads are also inserted, connected to another pair of terminals at the head, and are made to oppose the ordinary leads in the measuring arrangement, whereby the altering resistance of the pyrometer leads is rendered inoperative. The platinum is protected from furnace gases by surrounding the coil and leads with a porcelain tube. Fig. 9 shows a pyrometer of this pattern. In the Siemens resistance pyrometer, the wire is wound on a special fireclay and is preserved from damage by surrounding with magnesia and encasing in an iron tube, a single compensating lead being employed, joined up in the measuring device so as to cancel the variation in the ordinary leads. In America the Leeds-Northrup Company wind the platinum on lava instead of mica, and in

some cases use a differential galvanometer method to measure the resistance.

It is necessary, in industrial practice, that direct temperature readings on the gas scale should be obtained on the indicator, and in modern instruments this end is achieved in various ways. In the Siemens indicator an arm, moving round a dial, carries a tapping-key and on the edge of the dial is wound a wire resistance. The arm is moved round and the key tapped until no deflection is detected on the galvanometer mounted in the centre of the dial.

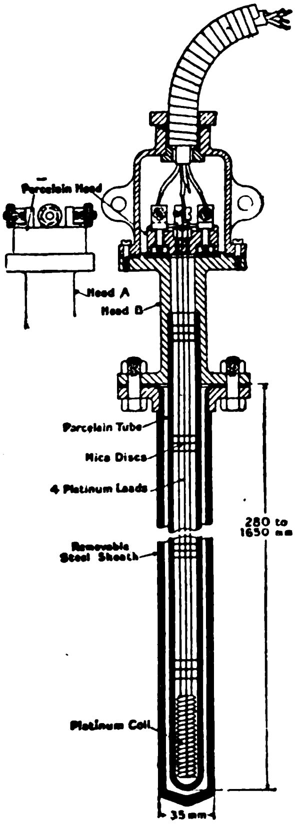

FIG. 9.—RESISTANCE PYROMETER.

(Made by the Cambridge Scientific Instrument Company.)

A pointer on the tapping-key then indicates the corresponding temperature by its position on the dial, and the measuring process is thus reduced to its simplest form. In Whipple's indicator, which also works on the Wheatstone bridge principle, the adjustable resistance is wound round a drum, and is operated by a handle connected to a screwed spindle which passes through a nut. Rotating the handle therefore imparts a spiral movement to the drum, and introduces a greater or less resistance in the arm of the bridge opposed to the pyrometer. A battery is brought into the circuit by the aid of a tapping-key, and the drum is turned until, on depressing the key, no deflection is noted on the galvanometer. The temperature may then be read off by noting the reading on a paper scale wound round the drum, a fixed pointer indicating the figure. The whole arrangement is contained in a single box for portability. These indicators are shown in Figs. 10 and 11.

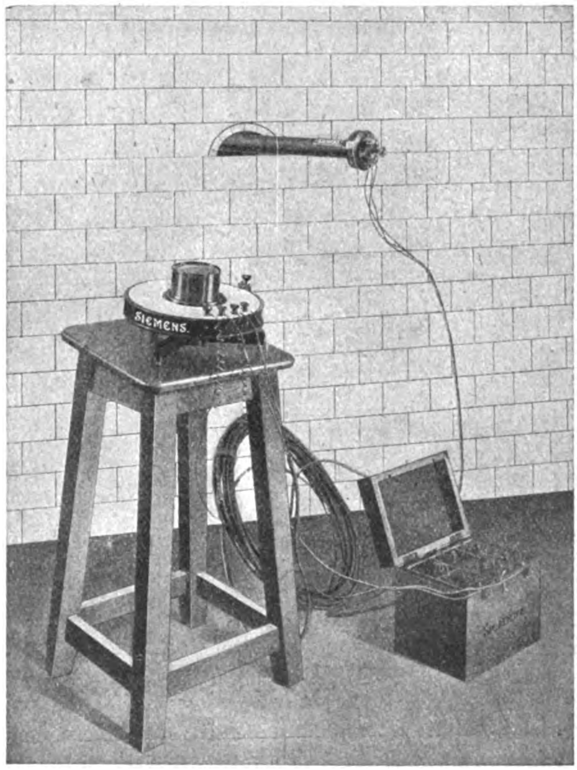

FIG. 10.—SIEMENS' RESISTANCE PYROMETER IN USE, WITH DIAL INDICATOR.

It will be observed that in both these indicators an experimental adjustment is necessary, which, although simple in character, takes up time and requires a moderate degree of intelligence to conduct properly. This drawback has not yet been completely overcome; but in the indicator made by Paul (Fig. 12), a series of step-resistances are provided, each representing an increase of 100° C. in the temperature of the pyrometer. The galvanometer scale is divided up so as to represent single degrees up to 100; and the procedure is to introduce the step-resistances until the pointer swings freely on

the scale, when the hundreds are read off from the steps and the units from the scale. In the latest form of this indicator the movement is electrically controlled, and is practically automatic. The Leeds-Northrup indicator works on the same principle, a voltmeter, however,

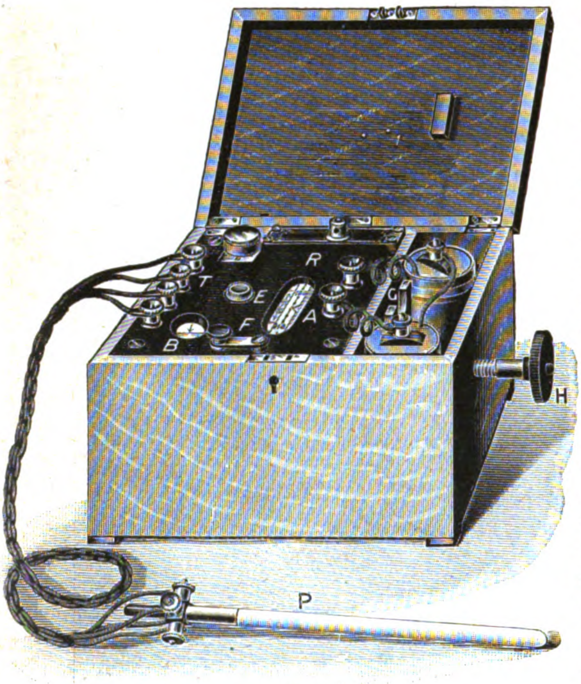

FIG. 11.—WHIPPLE'S INDICATOR.

replacing the more fragile galvanometer, and current from mains being employed to secure a sensitive indication, thus combining strength with accuracy. Both these instruments will indicate a fixed temperature without any manipulation, and in following a changing temperature it is only necessary to introduce another step as occasion requires. Both employ the differential method of resistance measurement.

We will now examine the possibilities of the finished instrument in industrial practice. The limit of temperature at which a resistance pyrometer may be continuously used is 1,000° C.; if this be exceeded for any length of time the resistance of the platinum is permanently altered, and the readings are thereby rendered erroneous. Below 1,000° C., however, it is possible to secure a more exact reading than can be obtained by the thermo-electric method; but this advantage is more apparent than real. In most cases it is not possible to control the temperature of a furnace to within less than 5° C.; and in such instances no advantage is secured by attempting to read to 1° C. Under special circumstances, where a high degree of accuracy is procurable and desirable, the resistance pyrometer is unrivalled for temperatures below 1,000° C. There are no errors to creep in analagous to those arising from alterations in the temperature of the cold junction of a thermo-electric pyrometer, and leads of any length may be used, provided the compensating leads are identical. On the other hand, the indications are not automatic, nor can the principle be easily applied to making an installation worked from a central office, owing to the difficulty of making each pyrometer of exactly equal resistance. In addition, the cost is greater than that of a thermo-electric outfit, and repairs are more difficult to execute. Hence the tendency is to employ the resistance pyrometer for very accurate work at moderately high temperatures, under conditions which demand a precision not to be obtained by the thermo-electric method. I show by the aid of slides several examples of the successful use of resistance pyrometers in the hot-air mains of blast-furnaces, biscuit-kilns for pottery, and annealing and tempering furnaces for the treatment of steel.

The first successful recorder for use with a resistance pyrometer was devised by Professor Callendar. In principle, this recorder (Fig. 13) consists of an arrangement by which the adjusting resistance in a Wheatstone bridge circuit is automatically made to equal that of the pyrometer by the movement of a slider over the

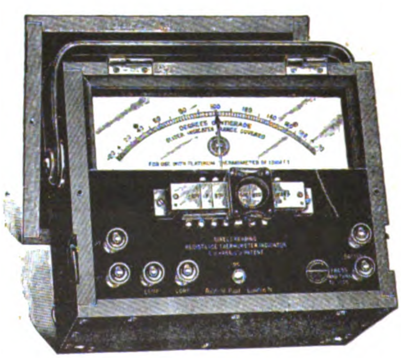

FIG. 12.—HARRIS'S INDICATOR.
(Made by R. W. Paul.)

resistance, a pen being carried by the sliding-piece which marks a graduated paper. The only part of a Wheatstone bridge circuit which

moves when the resistances are not adjusted is the galvanometer; and when the resistance introduced is greater than that being measured, the moving part of the galvanometer turns in one direction, and when less in the opposite direction. In Callendar's recorder a moving-coil galvanometer is used, and a boom attached to the coil is made to complete an electric circuit when the coil twists to the right, and another circuit when the coil turns to the left. The result in either case is to set in motion a mechanism which moves the slider along the resistance opposed to the pyrometer, the movement being to right or left according to the direction in which the galvanometer boom has moved, as the two mechanisms actuate the slider in opposite directions. When a balance is restored, the galvanometer boom will take up a central position, free of both contacts, and the sliding-piece will then be at rest. The paper in contact with the pen is wound on a drum, and made to rotate at a known rate by internal clockwork. If the slider carrying the pen remained at rest, a straight line would be traced on the paper, whilst movements due to fluctuations of temperature—and therefore of resistance—in the pyrometer will cause the pen to move to the right or left, thus drawing a sinuous line on the chart from which the temperature at any time may be deduced. Two slides are now shown to illustrate the utility of this recorder; in the first, the comparative merits of two stokers, who had instructions to keep a furnace at a given temperature, are clearly shown, together with the exact times when the furnace was neglected; and in the second slide we have a record of the heating and cooling of a piece of steel, on which the recalescence point is clearly shown, furnishing a guide to the subsequent treatment of the steel for the purpose intended.

It will be readily understood that the Callendar recorder contains, of necessity, mechanism of a delicate character, and requires careful handling. The galvanometer boom has to be relied upon to make a certain contact so as to complete the circuit which actuates the mechanisms; but the force with which the boom is pressed against the contact-surface is very small indeed, being due to the axial twist of the coil to which the boom is attached. Dr. Northrup, of Philadelphia, has recently designed a recorder in which this difficulty is overcome in the manner indicated in the diagram. The galvanometer boom G moves beneath two blocks of silver, A and B, separated by a thin strip of ivory. Beneath the boom is a silver block C, which is lifted by clockwork at stated intervals, so as to squeeze the boom between the upper and lower blocks. If the end of the boom be beneath A, the circuit E is completed, and actuates a mechanism which moves a pen along the adjusting resistance so as to restore the balance; if beneath B the circuit F is completed, and the pen moves in the opposite direction. If in a central position, as will be the case when the opposing resistance is equal to that of the pyrometer, the

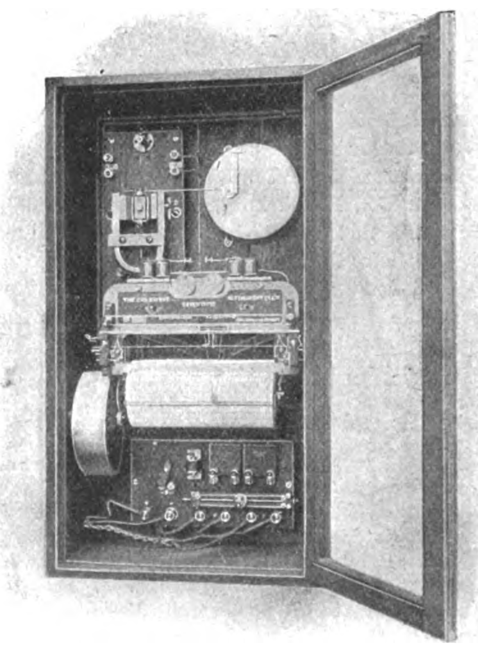

Fig. 13.—Callendar's Recorder.

boom will be pressed against the ivory, and neither circuit will be completed. In this recorder a differential galvanometer is used in preference to a Wheatstone bridge arrangement; but certain incidental difficulties remain to be overcome before the instrument is available for commercial use. Under the special conditions prevailing in a laboratory this recorder has already yielded excellent results.

In the hands of modern instrument makers, the resistance pyrometer, like the thermo-electric, has been converted from a crude and unreliable instrument to one of great utility

and accuracy. Yet all pyrometers which are kept permanently at high temperatures, and especially at any point above 1,000° C., undergo deterioration in the course of time. Even for occasional readings, when specially made for the purpose, the highest reading obtainable is the melting point of platinum, 1,753° C.—a temperature often exceeded in modern industrial operations. Evidently it would be an advantage if correct readings could be secured by means of an instrument, no part of which need be placed in the furnace, and which would be capable of measuring more exalted temperatures than is possible when pyrometers of the types previously described are used. Fortunately, modern scientific discoveries have enabled such instruments to be placed at our disposal, and they will form the subject of the fourth and concluding lecture.

[The following instruments were exhibited:—

Resistance pyrometers by Messrs. Siemens Bros. & Co., R. W. Paul, and the Cambridge Scientific Instrument Company, together with indicators for the same.

A Callendar recorder by the Cambridge Scientific Instrument Company.]

FIRST ANNUAL REPORT OF THE PORT OF LONDON.

The appearance of the first Annual Report of the new Port of London Authority is an event of more than ordinary interest. It was nearly eleven years ago that the increasing difficulties and complexities surrounding the ever-growing business of the Port brought home to the public with irresistible force and conviction the need of a general consolidated body or authority to overtake the functions properly attaching to a mass of well-defined duties and responsibilities. As is well known, a Royal Commission was the immediate outcome, and though enquiries of this character are sometimes unfairly criticised, it speaks well for this particular Commission that it conducted its investigations in a thoroughly business-like and practical spirit. In the short space of two years it had agreed upon a unanimous Report, which in its essentials was found to commend itself to the common-sense of Parliament and the public. Though the recommendations were naturally of a very voluminous character, involving as they did the transfer of great departments and undertakings from quasi-private hands to one public body, the initial requirement was, of course, the constitution of this central amalgamated authority.

The Port of London Authority consists of fewer members than originally contemplated by the Royal Commission. It comprises thirty members in all, the Chairman being Lord Devonport (formerly Sir Hudson E. Kearley, Bart.). Ten of these are "appointed" and nineteen "elected" members, but as a matter of practical convenience the elected members were appointed by the Board of Trade, after consultation with persons and bodies having knowledge and experience of trade or shipping in the Port. This was done in consequence of the inconvenience and delay that would have attended the preliminary organisation of the electoral machinery at the very outset of affairs.

One of the chief steps was the transfer of the undertakings of the three dock companies, viz., the London and India, Surrey Commercial, and Millwall Dock Companies, the stock of which constituted a total of £22,362,859, bearing interest amounting to £802,993 per annum. This new Port stock was officially quoted on the Stock Exchange on June 25th, 1909. Another undertaking transferred to the Authority was the Watermen's Company, whose incorporation dates back from 1827, and had actually originated in a guild dating from early in the sixteenth century. This company had for many generations exercised, under various Acts, the monopoly of the navigation of the river.

One important measure connected with the launching of the new Authority has been the enabling them to levy rates on river-borne goods entering London. This method of raising revenue for the purposes of the Port is, of course, an innovation in the case of London, being apparently framed on the precedent of Liverpool. To guard against its operating as an enhancement of prices, it is provided that the receipts from this impost must not exceed one-thousandth part of the aggregate value of the foreign goods imported and exported, or one three-thousandth part of goods imported or exported in vessels which do not go into any of the docks. The detailed schedule of rates was, under the authority of the Board of Trade, submitted to Lord St. Aldwyn, who held a public enquiry for the purpose of settling these rates on an equitable basis. A minor but important function of the Authority is concerned with the licensing or registration of craft, barges, boats and tugs, which hitherto, while enjoying exceptional privileges under what is known as "free-water conditions," have made but little, if any, contribution to the revenue of the Thames Conservancy or the dock undertakings. The estimated annual yield of these rates is about £13,000 per annum.

The total net tonnage of vessels that entered and cleared with cargoes and in ballast from and to foreign countries, British possessions and coastwise, at the Port of London during the year 1909, was 35,151,799 tons as compared with 33,768,599 tons during the year 1908.

The value of the total imports and exports

excluding coastwise goods) of the United Kingdom and the six principal ports was as follows:—

	1908.	1909.
U. Kingdom .	£1,049,681,008	£1,094,230,123
London . .	304,869,133	322,614,363
Liverpool . .	282,439,334	298,217,839
Hull . . .	61,555,005	66,672,983
Manchester .	40,403,763	43,508,069
Southampton.	38,157,776	42,116,457
Glasgow . .	41,695,383	41,238,867

Among the principal goods warehoused by the Authority are grain, timber, wool, frozen meat, tobacco, sugar, tea, wines, and spirits. The landings of grain for warehousing imported into London during the year ending March 31st last, showed an increase over those of the previous twelve months, the increase being mainly from Russia and Australia, the shipments from the United States and the Argentine showing a decrease. A large expansion is observable in the importations of Soya beans from Manchurian and Japanese ports. Timber showed an increase of about 180,000 tons, soft wood having risen while hard wood fell off, owing to shortage in the shipments of mahogany. Wool reached the Port in larger quantities, but there was a decrease in the number of bales sold in the London market, owing to larger sales having taken place in the Colonies, leading to direct shipments thence to the manufacturing districts. The frozen and chilled meat importations into London were 297,000 tons, of which about 45 per cent. was dealt with by the Authority. The whole of the tobacco warehoused in London is stored with the Authority, and the stock, on March 31st last, was 17,204 tons.

There is a vast amount of work in the way of developments and improvements which has been imposed upon the Authority by Parliament, and which will have to be carried out as soon as the new sources of revenue recently sanctioned are available. The evils complained of include insufficient depth of water in the docks, preventing the largest ships from using the Port, and causing loss and inconvenience by the detention of cargo to those frequenting it. Complaints are also rife of want of adequate dry-docking facilities, and of greater depth and width of the river channels to ensure freedom of ingress and egress to and from the docks, wharves, and discharging berths in the river. As for the dock properties and premises—these were generally found to be in want of proper repair, and to effect this will cost, so it is estimated, about £735,611. Of this a small proportion of £70,000 only has been put in hand, the remainder being reserved for future expenditure.

The maintenance of the river channels is essential to the existence of the Port. A navigable channel 1,000 ft. wide and 30 ft. deep at low water spring tides between Tilbury and the open sea was undertaken in 1907, and during the year ended March last, over two million cubic yards of material were raised. Progress is being made with the further deepening of the river to the same extent (30 ft.) as far as the Royal Albert Dock, and thence to London Bridge in gradually shallowing sections. For this purpose additional, and costly dredging plant will be required.

One of the most interesting incidents connected with the Authority is the grant to them by King Edward VII. of special armorial ensigns in which His late Majesty's own arms have been incorporated with those of King Edward II., in whose reign the Port of London was first opened. These ensigns have also been used for the purposes of the Common Seal of the Authority.

HOME INDUSTRIES.

Mining Accidents and the Eight Hours Act.—The Hulton Pit tragedy has served, among other things, to direct attention to the growing frequency of mining accidents. For fifty years the average mortality from accidents among our underground workers fell continuously. It fell from 5,149 to 1,411 per million persons employed underground, and the rate in the case of explosions fell from 1,280 in 1851-5 to 108 in 1896-1900. But during the last six or seven years the rate has been going up again, both as to accidents in general and explosions in particular. 1909 was the worst since 1896, the general rate having risen from 1,348 to 1,621; and the explosion rate from 20 to 272. In 1910 both rates showed further advance. What is the explanation of this very disquieting change? In his presidential address at the Scottish Miners' Federation, Mr. Snellie referred to the increase of accidents, which he described as very alarming, but ventured upon no explanation. The *Times* suggests that the last Workmen's Compensation Act has something to do with the increase in accidents. "It fosters carelessness, as the men are much less eager than they otherwise would be to avoid accidents in the first instance." But it is a rather far-fetched argument that the certainty of compensation leads to carelessness. Do men risk death more freely for being insured? Is the railway traveller who takes out an insurance ticket for the journey less anxious to avoid accident than his fellow-travellers? A much more plausible explanation is suggested by Mr. T. Good, who argues that the explanation is to be found in the Eight Hours Act. His contention is that this Act brings into existence "a whole combination of factors that add to the dangers of the miner's naturally dangerous occupation." It imposes uniform hours and conditions upon an industry in which both natural and economic circumstances vary widely between district and district, and even between mine and mine. And as with the pits and the business, so with the miners. The young man is able and willing to rush. The aged man is content to take his time. But the eight hours law treats all alike —"it sets nature, economics, and men alike at defiance." Under it "speeding up" will become a fine art in many mines. Already our miners are complaining that the owners are not only intro-

ducing dangerous new appliances and speeding up the work in every way possible, but that in order to maintain output they are employing additional hands who have not been used to mining and are thus a source of danger. And then the miners themselves, to counterbalance as far as possible the reduction of their earning time, pay less attention to bar-setting, propping, and other precautions. Moreover, the Act tends to oust the elderly workmen. The Act encourages mine-managers to get rid of their old men, who are slow, and employ vigorous young men in their place, and this means a gradual substitution of inexperienced and reckless men for experienced and cautious men. "The loss of the elderly pitman—the loss of his caution, watchfulness and advice will be an incalculable loss. The Eight Hours Act not only puts a big premium on speeding up, it places experience at a big discount." It may be objected that the Eight Hours Act cannot be wholly responsible for the increase in mining accidents, since that increase has been going on for six or seven years, and the Act was only passed in 1909, but it is a reasonable conclusion from the evidence that the Act has had a good deal to do with the acceleration.

Railway Accidents.—The terrible accident to the Midland Scotch express at Hawes Junction invites the enquiry whether more may not be done to lessen the chances of collision. It is impossible to eliminate the personal element. The most careful of men are liable to error, and error in a signal may mean, as at Hawes Junction, an appalling calamity. It is suggested—the suggestion is always made after a railway accident due to defective signalling—that there ought always to be two men in the signal-box, because both are not likely to forget the same thing at the same time. To that it is replied that two men have a divided responsibility, unless there is work for two and each attends to his own, and that if they have a divided responsibility, and there is really work for only one at any given moment, one may be doing the work and the other looking on, or not even doing that. The mischief is usually done in a few seconds, and who is going to guarantee, year in and year out, the alert attention of the second man? Such guarantee is impossible, but the objection is not conclusive. It may be possible to lessen risk, though not entirely to eliminate it. Many "boxes" are in isolated and lonely positions; any man is liable at any moment to lapse of memory or to illness, and the great responsibility of direct signalling ought not to be dependent upon the avoidance of human fallibility. But the best check upon human failure is to be found in automatic precautions, and it is not easy to see how such accidents as the one at Hawes Junction could occur if the "lock-and-block" system were general, for under this system it is practically impossible for two trains, or engines, to be on any of the sections into which the line is divided at the same time. These automatic devices deserve the most careful and constant study. For example, it is claimed for the Brown-Mackenzie system—no opinion is expressed here as to the validity of the claim—that the Hawes Junction disaster would have been impossible had this system been in use on the line. The prime object of the inventors is to provide a system which can be used as the sole means of signalling on a railway, the indications being given in the engine-cab instead of on the wayside. With this object in view, the track equipment is arranged in such a way as to cause the trains themselves automatically to operate the signals. The method employed embodies the main principles of lock-and-block, but greater freedom in dealing with the traffic is said to be possible than with any previous application of the lock-and-block. The system may, however, be used as an auxiliary to any existing system of semaphore signalling (either automatically or manually controlled), in which case it may be controlled automatically and independently from the other system, or it may act simply as a signal repeater, giving the repeated signal in the cab of the engine.

Shipping and Managing Owners.—The managing owners of ships are largely responsible for the excessive amount of British tonnage in existence. The capable and energetic man who becomes a managing owner—the phrase used to be "a ship's husband"—is not restricted by those prudential considerations which in the past were obstacles in the way of excessive construction. His title is a misnomer. His personal stake in the ship is generally small. He is the agent of such of the owners of a ship as appoint him, and part owners are of all positions and both sexes. If he wishes to build a steamer, and can obtain a small proportion of the capital necessary to build and fit out a vessel, he can always find a builder who will allow a large part of the cost of construction to remain on mortgage. And he is paid by commission on the gross freight, a practice which—as a correspondent of the commercial supplement of the *Times* points out in an interesting communication—though excellent from his point of view, is fraught with evil. The system of payment by commission ensures the managing owner some remuneration, whether or not the actual owners obtain dividends. If, in a year or two the builders, or other mortgagees who have enabled the vessel to be built and equipped, take possession under their mortgage, the managing owner has for a time reaped a benefit from his speculation, though the whole capital of those who have invested in the ship may be lost. If, on the other hand, the vessel turns out to be a success, he is certain of a satisfactory return for some years, and of an increase of business reputation. In the opinion of the writer in the *Times*, the question will sooner or later have to be answered (in view of the large amount of shipping which is still unprofitable) whether the term "managing owner," which was inserted in the Shipping Acts for a definite non-commercial purpose, may not have to be regarded from a wider point of view. It may

be necessary, in consequence of the tendencies and progress of modern shipping, that every person who manages a vessel shall have an actual and substantial interest in her. And this seems the more reasonable, since the managing owner is in the habit of insisting that the master of a vessel shall invest a substantial sum in her, a condition that may well operate against the public interest, inasmuch as it tends to inefficient command. An old and incapable sailor who can put some money into a ship is often preferred by the managing owner to a younger and better seaman who cannot do so.

The Cotton Industry.—The year just ended was a bad one for the cotton industry, bad for employers and bad for operatives. The capital invested in spinning and weaving concerns has not been remunerative, and the workpeople have not been fully employed. The bottom of the trouble was the high prices in raw cotton. The year opened with Middling American cotton on the spot in Liverpool quoted at 8·44*d*., and the quotation at the end of the year was 8·12*d*., the lowest price in the intervening period being 7·56*d*., the quotation on January 21st. In Egyptian cotton, prices were on a higher level at the beginning of the year, Fully Good Fair Brown being quoted at 13¾*d*. At the end of March the quotation had risen to $16\frac{3}{16}d.$, but at the close of December it had fallen to $11\frac{1}{16}d.$ As to the future, the outlook is not encouraging so far as America is concerned, where the crop is estimated at 11,600,000 bales. In Egypt, the official estimate of the Alexandria General Produce Association is 7,000,000 cantars. From India the reports are not so favourable. The big Egyptian crop will to some extent make up for the smaller supply in the American staple, but it seems certain that the raw cotton supplies of the year will not be sufficient to prevent some shortage, and high prices must be expected. Users of Egyptian cotton did better last year than spinners of American yarn, but a good deal of money was lost in both departments. Statistics just issued show that the loss on share capital for the twelve months ended November 30th was over 10 per cent. It has been the worst year for shareholders since the limited liability company came into existence.

OBITUARY.

P. K. Rajam Ayar.—Intimation has just been received of the death of Mr. P. K. Rajam Ayar, which took place on October 4th, 1910, at the age of 52. Mr. Rajam Ayar was for upwards of ten years Tahsildar of Trichinopoly, and was about to retire from the public service. He was keenly interested in archæology. He became a life member of the Royal Society of Arts in 1900.

NOTES ON BOOKS.

Studies in the Decorative Art of Japan. By Sir Francis Piggott. London: B. T. Batsford. 25*s*. net.

This work is quite evidently a labour of love. The Nikko and Shiba temples have been well-loved haunts of Sir Francis Piggott, and his interest in tracing the evolution of symbolic diapers and borders is keen and sustained. The studies are rather loosely strung together, but the author has much to tell that is interesting, and the separate papers are fairly complete, whilst the illustrations, both in black and white and in colour, are well worth studying.

There is, perhaps, not very much to be said about the early part of the volume, which deals with Temple Decoration and is divided up under the headings of "The Decoration of Flat Surfaces," "Wave and Cloud Forms," and "Lattice Work," except that the author is dealing with an interesting and little known subject in a deeply sympathetic spirit.

The paper on "The Use of the Circular Form" is one which should appeal strongly to designers, and to teachers of design, as it explains very fully the method of sub-dividing the circle adopted by the Japanese, and gives many examples of their power of successfully conforming what appear to us the most rigid and unbending forms to a circular shape.

The long paper on "The Pakwa Diapers and Keyborders of the East," which closes the volume, and which includes, by the way, a discussion of the origin of the *Svastika*, is the only controversial part of the book. The origin of the key pattern has been so hotly disputed that agreement between the advocates of different theories seems too much to hope for, but Sir Francis Piggott certainly makes out a very ingenious case for the border having been derived from an all-over *Pakwa* diaper —and he proves quite conclusively that it could have been evolved from *Pakwa* elements. Whether it necessarily was so derived is rather a different question, and one which will probably receive different answers according to the bias of the people interrogated. The antiquarian will probably always look for its origin in some particular country, whilst the designer is more inclined to regard it as a form of decoration which might quite well have been evolved independently in a number of different places, as the outcome of a desire for simple decoration and the habit of working with simple tools or appliances.

Educational Aims and Efforts. By Sir Philip Magnus, M.P. London: Longmans, Green and Co., 1910.

For the past thirty years Sir Philip Magnus has been closely associated with the progress of technical education in this country, and the book which he has just published is a record of much

valuable educational work. The greater part of it is a reprint of the various addresses which the author has given on educational subjects, and these alone show the progress which has been made, and the change of view which has taken place (much of which change, indeed, is due to Sir Philip's own labours) during the past five-and-twenty years. Besides this, there is an introductory chapter, the most interesting portion of which is, perhaps, Sir Philip's account of the early history of the City and Guilds of London Institute, of which he was appointed organising director and secretary in 1880.

Sir Philip commences his narrative with his own appointment. But a good deal of useful work had already been done, and it would have added to the interest of this chapter of the book if some account of the early origin of this important association had not been omitted.

It should also be mentioned that much of Sir Philip Magnus's useful work in connection with the University of London finds a record here, and this goes back even to an earlier period than 1880, the date at which the book professes to commence.

GENERAL NOTES.

Bulgaria and British Trade.—In his report on Bulgaria just issued (No. 4,609 Annual Series), the Hon. F. O. Lindley, Secretary to His Majesty's Legation at Sofia, is able to report that in the quinquennial period 1905-9, British exports to Bulgaria increased, but this increase was not very considerable, and Mr. Lindley hints at some of the reasons. He reminds merchants that commercial travellers with a knowledge of foreign languages are the best means of obtaining business in foreign countries; that few people in Bulgaria understand English, and that still fewer comprehend either English money values or English weights and measures; that catalogues, therefore, to be of any use, should be drawn up either in Bulgarian, or in French or German, with values in francs or marks, and, above all, with metric weights and measures, which are those in use in Bulgaria; finally, that other things being nearly equal, the merchant who gives credit obtains the order. With regard to this latter point, Mr. Lindley does not suggest that merchants should give indiscriminate credit; such a course would be quite as disastrous to them in Bulgaria as it has proved recently to some of their rivals in North China. But a good deal of business is lost in Bulgaria owing to a rigid insistence on cash against documents, and it is possible to give a certain amount of accommodation, if very careful enquiries are made as to the standing of the persons dealt with. In this connection it may be mentioned that there is still no British bank represented in Bulgaria, although for years one has been talked of. Such an establishment could hardly fail to promote British commercial interests, and Mr. Lindley thinks it would also prove remunerative from a purely banking point of view.

Swiss Watches.—The value of the watches exported from Switzerland in 1909 fell by about 20 per cent. as compared with the figures for the preceding year, but the number of watches exported increased by 332,500. The prices of watches with cases of nickel or other common metals fell to a very low figure, while those for silver watches again slightly receded. On the other hand, the average price obtained for gold watches was higher than at any time during the last ten years. Some figures quoted by Mr. Vice Consul Milligan, in his report upon the trade of Switzerland just issued (No. 4610 Annual Series), show a rather surprising distribution of Swiss watches exported. Germany took 294,551 gold watches as against 133,470 that came to the United Kingdom, and 691,878 silver watches as against 258,320 imported by this country; but of nickel watches Germany took only 444,411 as compared with 1,379,745 that came to Great Britain. One would have thought that the cheaper article would have been more in demand in Germany. The Swiss manufacturers are much concerned at the foreign competition, which is seriously affecting the Swiss watch industry, and the official report upon the industry directs the attention of Swiss manufacturers to the national danger in supplying foreign manufacturers with detached parts of watches.

Argentine Centennial Exhibitions, 1910.—In the General List of Awards at the Argentine Railway and Land Transport Exhibition, Great Britain easily secured the first place with 222 awards, her nearest competitors being Germany with 171 awards, Italy with 155, France with 122, and the United States of America with 72 awards. These totals are made up as follows: Great Britain, 82 grands prix, 12 diplomas of honour, 75 gold medals, 39 silver medals, and 12 bronze medals; Germany, 70 grands prix, 35 diplomas of honour, 41 gold medals, and 18 silver medals; Italy, 70 grands prix, 35 diplomas of honour, 40 gold medals, and 5 silver medals; France, 64 grands prix, 25 diplomas of honour, 25 gold medals, and 4 silver medals; and the United States, 21 grands prix, 8 diplomas of honour, 33 gold medals, and 6 silver medals.

Chinese Machine-made Embroidery. — The adaptation of an ordinary sewing machine to the making of silk embroidery has been taken up by the Chinese in Hong-Kong, and in other places in South China, with considerable enthusiasm, and although the idea was put into execution only a little over one year ago, the progress made in producing really handsome machine work is notable. It is the Chinese ladies of the better class who are learning to make embroidery, and in Canton, for

instance, some of the more wealthy ladies have organised classes in their respective residences in order to study the art further, for it is not simply a matter of the machine doing all that is required, but much scope is left for the individual in designing as well as colour shading. The work is done chiefly on Chinese raw silk (at the beginning Japanese was used), and comprises all kinds of designs—scenery, bird life, flower studies, emblematical scrolls, etc. The only foreign substance that enters into the work is the bobbin thread of cotton. No restrictions are placed on the designs, and the varieties of embroideries made show exquisite taste, and likewise excellent judgment is displayed in the grouping of the colours. In Hong-Kong there are about thirty young Chinese women who are learning the art, the majority doing this purely as a pleasant pastime, and this method of producing beautiful work of uniform quality seems to appeal strongly to them. There are three teachers—an artist to teach drawing, designing, and colour-shading, an instructress in the actual embroidery work, and an instructor in the use of the machine.

THE PRODUCTION OF GUM TRAGACANTH.—The yield of gum tragacanth for 1910 is said to be about one hundred and forty tons as compared with about two hundred tons in 1909. This gum is the product of a plant growing wild in the mountainous region of Cappadocia, Asia Minor. The plant is a small bush which grows only at an altitude of 4,500 to 7,500 feet, and is most plentiful on the slopes of Mount Argæus, 12,560 feet high, of the Taurus Range near Cæsarea. In June the earth is scraped away from the base of the stem of the plant and incisions are made near the root. The sap, which gradually oozes out, hardens into spiral formations. The first exudations are whitish, and these are the most desirable, especially in the American market. As the earth which has been scraped away lies loose about the plant, should any rain fall while the gum is forming it will wash the loose soil upon the exuding sap, and thereby discolour the resulting gum. This was especially true in 1910, and hence the yield is inferior both in quality and in quantity. As a matter of fact it is mostly discoloured. The prices were higher in 1910 than in 1909, and the prospects are that with a steady demand they will be still higher. Cæsarea is the principal market for tragacanth gum, but it is mostly transported by camels to Mersina, whence it is shipped to Europe and America. In 1909 the total exports were valued at £28,000. The gum is employed in the arts, and by druggists in the preparation of lozenges and emulsions, to hold the basic element in suspense.

REINFORCED-CONCRETE SLEEPERS AND FENCING POSTS.—About a quarter of a mile of the London and North-Western Railway Company's "up" line immediately north of Pinner Station has been laid with sleepers formed of reinforced-concrete. These sleepers are placed somewhat closer together than those made of timber, and except where the chairs are placed they are of smaller section. It is understood that if the experiment shows satisfactory results, the use of concrete for the purpose will be extended. The company have already had steel sleepers under trial, but the experience gained with them was not encouraging, as it was found that they tended to make the track far more noisy when under traffic. According to the *Timber News*, reinforced-concrete is now being also adapted for fencing posts of various descriptions. With regard to the cost, it is stated that in one instance a railway fence has been erected complete at about 1*s.* 8*d.* a yard, and that in many places cement, sand, and iron, can be obtained and made into posts at a price less than that of deal. It is suggested that the life of these posts should be very long, say one hundred years, whereas that of deal untreated with preservative is only about ten years, or, if creosoted, about twenty. Among railway companies, the London and North-Western, the Great Northern, and the Great Eastern, have erected fence posts of this description.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 18.—JOHN C. MEDD, M.A., "The Dutch Labour Colonies." LORD REAY, G.C.S.I., G C.I.E., will preside.

JANUARY 25.—HORACE M. WYATT, "Motor Transport in Great Britain and the Colonies."

FEBRUARY 1.—PHILIP JOSEPH HARTOG, M.A., B.Sc., "Examinations and their bearing on National Efficiency." The EARL OF CROMER, G.C.B., O.M., G C.M.G., K.C.S.I., C.I.E., Vice-President of the Society, will preside.

FEBRUARY 8.—Captain A. J. N. TREMEARNE, B.A., D.Anth., "Some Nigerian Head-Hunters."

FEBRUARY 15.—GEORGE A. STEPHEN, "Modern Machine Book-binding." JOHN MURRAY, J.P., D.L., F.S.A., will preside.

FEBRUARY 22.—Professor J. WERTHEIMER, B.Sc., B.A., "Water-Finders."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

JANUARY 19.—REGINALD MURRAY, "Banking in India." Sir FELIX SCHUSTER, Bart., will preside.

FEBRUARY 9.—R. A. LESLIE MOORE, I.C.S. (retd.), "Indian Superstitions."

March 16, April 27, May 25.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

JANUARY 31.—F. DOUGLAS OSBORNE, M.Inst.M.M., "The Tin Resources of the Empire."

FEBRUARY 28.—The HON. SIR RICHARD SOLOMON, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "The Resources and Problems of the Union of South Africa."

APRIL 4.—Captain R. MUIRHEAD COLLINS, C.M.G., "Australia and her Resources."

MAY 9.—F. WILLIAMS TAYLOR, "Canadian Banking."

CANTOR LECTURES.

Monday Evenings, at 8 o'clock:—

FREDERICK WEDMORE, "Etching." Two Lectures.

LECTURE I.—JANUARY 23.—"The Old Masters." The Cradle of great Etching—Rembrandt's place—Ostade and Bega—Vandyke—Landscape and Animal Subjects in the Low Countries—The Classic Landscape—Claude—Links with the Moderns—Etching no "Minor Art."

LECTURE II.—JANUARY 30.—"Modern Etching." Goya—Wilkie and Geddes—The Silence before the Revival—The great French Outburst—Méryon, Bracquemond and Jacquemart—Haden and Whistler—Themes mainly Landscape, Portraiture, Architecture—The Etching of To-day.

Professor ADRIAN J. BROWN, M.Sc., "Brewing." Four Lectures.
February 6, 13, 20, 27.

Professor J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.
March 6, 13, 20, 27.

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.
May 1, 8, 15, 22.

Dates to be hereafter announced:—

FRANK M. ANDREWS, "Architecture in America."

ARTHUR CHARLES DAVIS, F.C.S., Assoc.Inst.C.E., "The Manufacture and Testing of Portland Cement."

GEORGE B. HEMING, "Art Education in Jewellery and Goldsmithing."

Colonel CHARLES EDWARD CASSAL, V.D., F.I.C., "The Adulteration of Food."

Dr. LEONARD HILL, F.R.S., "Caisson Sickness and Compressed Air."

Sir WILLIAM ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

HAL WILLIAMS, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

NOEL HEATON, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

Sir THOMAS HENRY HOLLAND, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." LORD AVEBURY, D.C.L., LL.D., F.R.S., will preside. (Indian Section.)

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 9...Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Mr. Otto C. Overbeck, "The Production of Alcohol in Beer without Fermentation."

Victoria Institute, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Rev. J. J. B. Coles, "Theosophy."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. E. H. Blake, "Notes on Highway Law as affecting Property Owners."

Geographical, in the Theatre, Burlington-gardens, W., 3 p.m. (Juvenile Lecture.) Dr. Vaughan Cornish, "Scenes and People in Jamaica."

Engineers, Cleveland Institute of, Corporation-road, Middlesbro', 7.30 p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Professor E. Gardner, "Art as Expression and as Illustration."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. H. H. Statham, "Architecture as Plan and Section."

TUESDAY, JANUARY 10...Asiatic, 22, Albemarle-street, W., 4 p.m. Dr. M. Gaster, "Turkish History from Jewish Manuscripts."

Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor S. P. Thompson, "Sound: Musical and Non-Musical. Lecture VI. —Reproduction of Sound."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. William Dawson, "The Strengthening of the Roof of New Street Station, Birmingham," and "The Reconstruction and Widening of Arpley Bridge, Warrington."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. F. Martin-Duncan, "Application of Photography to Biology."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Sir Daniel Morris, "The Imperial Department of Agriculture in the West Indies."

WEDNESDAY, JANUARY 11...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. (Juvenile Lecture.) Professor A. M. Worthington, "A Study of Splashes, Conducted by the aid of Instantaneous Photography." (Lecture II.)

Biblical Archæology, 37, Great Russell-street, W.C., 4.30 p.m. Paper on "The Tombs of the Kings at Jerusalem."

Geological, Burlington House, W., 8 p.m.

Automobile Engineers, at the Institution of Mechanical Engineers, Storey's Gate, S.W., 8 p.m. Mr. F. R. S. Bircham, "The Development of Engines for Marine Purposes."

THURSDAY, JANUARY 12...Cyclists' Touring Club (Metropolitan District Association), at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.30 p.m. Mr. E. C. Russell, "With the M.D.A."

Architects, Society of, 28, Bedford-sq., W.C., 8 p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. D. G. Hogarth, "Cretan Discoveries."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. W. Bickerton, "Wild Birds and their Ways."

Electrical Engineers, Victoria Embankment, W.C., 8 p.m. Discussion on paper by Major W. A. O'Meara, "Submarine Cables for Long Distance Telephone Circuits."

Engineers, Junior Institution of, at the United Service Institution, Whitehall, S.W., 7.30 p.m. Mr. H. F. Donaldson, "Depreciation of Buildings and Machinery."

FRIDAY, JANUARY 13...Royal Drawing Society, in the Art Gallery, Guildhall, E.C., 4.30 p.m. 1. Annual General Meeting. 2. Mr. T. R. Ablett, "A Method of Developing Visualisation."

Journal of the Royal Society of Arts.

No. 3,034. VOL. LIX.

FRIDAY, JANUARY 13, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 18th, 8 p.m. (Ordinary Meeting.) JOHN C. MEDD, M.A., "The Dutch Labour Colonies." Lord REAY, G.C.S.I., G.C.I.E., will preside.

THURSDAY, JANUARY 19th, 4.30 p.m. (Indian Section.) REGINALD MURRAY, "Banking in India." Sir FELIX SCHUSTER, Bart., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COVERS FOR JOURNALS.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s*. 6*d*. each, on application to the Secretary.

JUVENILE LECTURES.

On Wednesday afternoon, January 11th, Mr. ARTHUR MASON WORTHINGTON, C.B., M.A., F.R.S., late Professor of Physics in the Royal Naval College, Greenwich, delivered the second and final lecture of his course addressed to a juvenile audience on "A Study of Splashes, conducted by the aid of Instantaneous Photography."

The lecturer began by referring to a question which had been put to him by one of his audience at the close of his previous lecture: "When a bubble is formed what becomes of the ascending central column previously seen?" The answer depends on the completeness and firmness with which the bubble is closed. Photographs showed in a very beautiful manner how, with a rather lower height of fall, the bubble reopened immediately and made way for an emergent column bearing the original drop on its summit. At other times the rising column forced its way through the bubble, causing a temporary irregularity which, however, was soon smoothed away under the influence of the surface tension.

The splashes of solid spheres were then examined. Well-polished marbles were dropped into a deep glass bowl full of water, and the audience could see that they slipped in noiselessly with hardly any visible splash. The same spheres if wet, or roughened with sandpaper, or even if dusty, made a great noisy, bubbly splash accompanied by the projection into the air of a tall jet of water whose summit rose even higher than the place from which the marble fell. In order to explain this astonishing difference, each kind of splash was then followed in detail by means of the instantaneous photographs, which showed what happened both above and below the surface.

With the rough sphere the crater thrown up was curiously like that accompanying the splash of a liquid drop, and can be described as a "basket" splash. The sphere in this case enters the liquid without really breaking the skin, which is drawn into a surprisingly deep cylindrical pocket containing air. This ultimately divides into two parts, the lower part constituting a bubble which is attached to the sphere and follows in its wake to the bottom of the containing vessel, when it becomes detached. Then, and only then, does the upper part of the sphere, hitherto perfectly dry though far below the surface, come into contact with the liquid. Meanwhile, the upper part of the air-column forms a deep, hollow basin, into which the liquid flows from all sides. The converging streams, which gain velocity as the channel narrows towards the centre, there meet, and, spirting upwards, form the ascending column.

With a smooth sphere, on the other hand, the splash is totally different from the very first instant of contact. For the liquid, instead of being driven laterally away, is retained by

the force of adhesion, and guided over the solid surface so as to envelope it in a liquid sheath of exquisite thinness: thus the sphere becomes covered with liquid before it is even below the general level of the surface. One very instructive photograph, obtained originally by accident, showed how a sphere polished on one side, and rough, or dusty on the other, produced simultaneously the two kinds of splash—the "basket splash" and the "sheath splash." The effect of increasing the height of fall of a rough sphere to anything from 5 to 25 feet was then examined. As the audience had already seen, the tall, rebounding column now disappeared, but the photographs revealed a very astonishing new phenomenon—namely, the formation of an interior jet of liquid following the sphere downwards through the middle of the long air column. [It is impossible to give any clear idea of the origin and appearance of this phenomenon without reproducing the photographs themselves.] It was shown that the final condition reached was that of a double vortex-ring, one accompanying the sphere and one remaining at the surface.

In conclusion, Professor Worthington showed to the audience the under-water air-column of a "basket splash" just in the act of dividing, projected on the screen by means of an electric flash produced at the right instant.

On the motion of the Chairman, a vote of thanks was accorded to the lecturer for his interesting course.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

INDUSTRIAL PYROMETRY.

By Charles R. Darling, A.R.C.Sc.I., F.I.C.

Lecture IV.—Delivered December 12th, 1910.

Radiation Pyrometers.

It was remarked in the first lecture that Newton, in 1701, made an attempt to measure the temperature of a coal fire by a method depending upon the rate at which an iron bar, drawn from the fire, radiated energy to its surroundings. In the last century many observers, taking advantage of Nobili's thermopile, endeavoured to determine a relation between the energy falling on the thermopile and the temperature of the radiating source. Amongst those who worked in this direction was Tyndall, who recorded a number of results obtained by allowing the radiations from a platinum surface, heated to different temperatures, to fall on a thermopile, the deflection of the needle of the galvanometer in the circuit being noted for each temperature. These figures lay in the pigeon-holes of science for many years; but in 1879 Stefan of Vienna, on submitting them to a close examination, came to the conclusion that the energy radiated by the hot platinum varied as the fourth power of the absolute temperature. Stefan expressed the opinion that all solid bodies radiated energy according to this law, under certain attainable conditions of surface—a conclusion which has proved to be erroneous. It would be well at this stage briefly to consider the ordinary manifestations of radiant energy in this relation. Every substance, provided its temperature be above absolute zero, radiates energy by the medium of ether waves, and when the various objects in a room attain an equal temperature, each is radiating to its surroundings an amount of energy equal to that which it receives. The nature of the surface of a solid, however, plays an important part in connection with the quantity of radiant energy emitted or absorbed under given conditions. To illustrate this point I place a strip of platinum foil in front of a thermopile, and heat it to redness by means of a current of electricity. One face of the foil is bright, and the other coated with a dark oxide; and on presenting the bright side to the thermopile we obtain a deflection of the spot of light from the galvanometer to which the pile is connected. I now rotate the platinum strip so that the dark side is opposite the thermopile, when we observe that the deflection increases considerably, although the temperature has not altered. Evidently, therefore, it is necessary, in considering any radiation laws, to take the nature of the surface of the radiating body into account. Of all the surfaces examined, a dull black, such as soot or lampblack, is found to be the best both for radiating energy or for absorbing radiations which fall upon it; but even this surface is not perfect. A perfect surface, from the radiation standpoint, would absorb all radiations incident upon it, and none would be reflected or transmitted through it.

We may now return to Stefan's interpretation of Tyndall's results. In the year 1884 Boltzmann published a mathematical investigation of the subject, based on thermodynamic reasoning, and arrived at the same result as Stefan, namely, that the energy radiated by a hot substance

varied as the fourth power of the absolute temperature, provided — and herein lay the clarifying effect of Boltzmann's investigation—that the surface behaved as a perfect radiator of energy. I do not propose to-night to give the details of this valuable contribution to scientific knowledge; suffice it to say that two assumptions made in the investigation, viz., the existence of light pressure, and of the composition of the spectrum of radiation when changing in density, were afterwards proved to be justifiable by Lebedew and Wein. We are, therefore, not dealing with an empirical law, but with one capable of mathematical proof; and we may therefore apply this law with confidence in all cases where the condition of perfect radiation is realised.

If, however, no known surface acts as a perfect radiator, the question at once arises:—How is it possible to apply the fourth-power law in practice so as to measure temperatures? To answer this we must refer to the work of Kirchoff, who in 1860 pointed out that an enclosure, at a constant temperature throughout, would emit radiations through a small aperture in one side to exactly the same extent as would a perfect surface at the same temperature. Such an arrangement was termed by Kirchoff a "black body"—not that it is necessarily black in colour, but because it conforms to our ideas of absolute blackness in the sense of total absorption of radiations. As this conception of a "black body" has a most important bearing upon practical pyrometry, we will consider it a little more closely. If radiations enter an enclosure with opaque walls, they are evidently trapped in, and absorbed as totally as if they fell upon a perfectly-absorbing surface. To show that radiations leaving the enclosure through the opening are also equivalent to those emanating from a perfect surface, we may consider a spot on the wall opposite to the aperture. Rays leaving that spot will be partly reflected, and partly radiated; but if the temperature be constant the amount leaving the spot will be equal to the amount received from the enclosure. Hence the rays passing out from the spot will be equal in amount, whatever the character of the surface, which, if perfect, would radiate all the energy; and which, if imperfect, would radiate some and contribute the balance by reflecting directly those rays which are not absorbed.

Now the value of all this in relation to pyrometry arises from the fact that almost all operations at high temperatures are conducted in enclosures which we call furnaces, and radiations from the interior of a furnace through a small opening in the side are true black-body radiations. Thus it fortunately happens that the very condition necessary to render the fourth-power law valid in practice is realised in almost all our industrial processes. There is also a simple method of obtaining black-body radiations even when the source to be measured is not enclosed, by placing a tube, closed at one end, in the hot space, and receiving the radiations from the open end. All that is requisite, therefore, is to obtain an instrument which will measure the quantity of radiant energy calibrated to read temperatures by the aid of the fourth-power law.

The first pyrometer on these lines was devised by Féry of Paris in 1902. It consisted of a kind of telescope, the object-glass of which focussed the rays from the hot source on a tiny thermal junction, after the fashion of a burning-lens. The thermal junction was coupled up with a delicate galvanometer, which by its deflections measured the relative quantities of energy falling on the junction under varying conditions. By taking one accurate reading of a furnace kept at a known temperature, the whole scale of the galvanometer could be divided so as to read in temperatures directly; thus if a known temperature of 927° C. (1,200° abs.) gave a deflection corresponding to 2 millivolts at the galvanometer terminals, then 5 millivolts at the terminals would represent a temperature of 1,227° C. (1,500° abs.). This value is calculated from the fourth-power law as follows:—

$$\frac{R_1}{R_2} = \frac{T_1^4}{T_2^4};\ \therefore\ \frac{2}{5} = \frac{1200^4}{T_2^4};\ \therefore\ T_2 = 1500^\circ \text{ abs.}$$

The temperature corresponding to any other deflection could similarly be calculated and marked on the scale.

In this form Féry's pyrometer suffered from a grave defect, which prevented a strict application of the radiation law to its readings. A large proportion of the radiant energy from a heated source cannot pass through glass, as we may observe from a simple experiment with the thermopile. I place a yellow gas flame in front of the instrument, and we obtain a deflection on the scale of the galvanometer. I now interpose a sheet of ordinary glass between the flame and the thermopile, and immediately the deflection falls off considerably. The proportion of the rays thus extinguished does not, moreover, bear any uniform relation to the temperature of the hot source; and although this difficulty might be overcome by the use of a fluorspar lens in place of the glass objective, the cost of such a

lens would make the instrument prohibitive for industrial purposes.

In 1904, however, Féry solved the problem by using a concave mirror to focus the radiations on the junction. I will repeat an old experiment to show how radiations may thus be focussed. Facing each other, on opposite sides of the room, are two concave mirrors, and in the focus of one is placed an electric arc, the rays from which strike the mirror behind it, and pass in a parallel beam to the opposite mirror, which brings them to a focus. I place a piece of guncotton in this focus; it immediately ignites; and a sheet of paper held in the same spot soon bursts into flame. The first mirrors used by Féry were faced with silver, which soon tarnishes in a workshop; but by using a gold reflecting surface this trouble was overcome. The construction of the pyrometer as now used is shown in the slide (Fig. 14), in which C is the concave mirror and R the junction on which the rays fall. The junction is made as small as possible, and possesses a dull, black surface, so that every type of radiation falling on it is almost completely absorbed and converted into heat. Terminals from this junction pass to a d'Arsonval galvanometer, which has a suspended coil, and which gives deflections proportional to the energy absorbed by the junction, and is marked with a temperature scale as previously explained. Now the position of the focus formed by a concave mirror varies according to the distance of the object focussed, and as the image of the hot substance must be formed exactly on the junction, some accommodation is necessary. This is furnished by a rack and pinion movement, by means of which the position of the mirror may be adjusted by turning the milled-head E. To discover when the focus is correct, a small telescope is provided, fixed opposite to a hole in the centre of the mirror. By means of an ingenious optical device, the image of the hot substance produced by the mirror is reflected back to the telescope in the form of two semi-circles, and the focussing process consists simply in moving the mirror until the two half-moons form a full moon or continuous circle, when the temperature may be immediately read off on the scale. The thermal junction is visible through the telescope, and so long as it is completely overlapped by the image the same temperature is recorded. For, although the radiant energy entering the instrument falls off as the square of the distance, this is balanced by the fact that the area of the image formed by the mirror diminishes in like ratio; and whereas at long range the whole of the reflected rays may impinge on the junction, at a small distance from the hot body the image is so large that the greater portion does not strike the junction at all, but passes after reflection out of the end of the tube. As constructed for workshop use, a heated object one foot in diameter will give the same reading at any distance up to twelve yards.

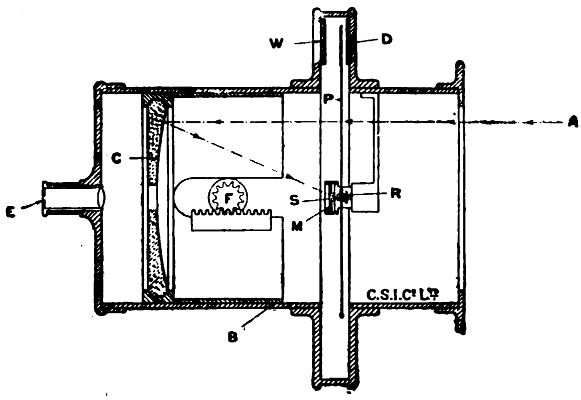

Fig. 14.—Section of Féry's Radiation Pyrometer, Spiral Form.
(In the ordinary form the Spiral S is replaced by a Thermal Junction.)

The history of the evolution of the Féry pyrometer furnishes one of the most striking examples of the manner in which a number of discoveries may be blended into a most useful instrument. Eight great names are inseparably connected with this device; the sighting telescope recalls Galileo; the concave mirror for bringing the rays to a focus in this form takes us back to Newton; the thermal junction was the discovery of Seebeck; the moving-coil

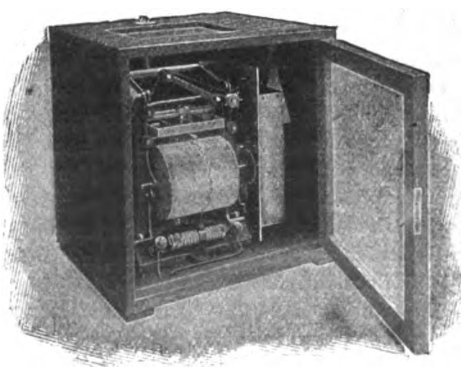

Fig. 15.—Thread Recorder, for use with Féry Pyrometer, or any Thermo-electric Instrument.

galvanometer originated with d'Arsonval; and the fourth-power temperature scale enshrines the names of Kirchoff, Tyndall, Stefan and Boltzmann. And, in all justice, we should add as a ninth name that of Féry, who so ingeniously combined the work of his predecessors.

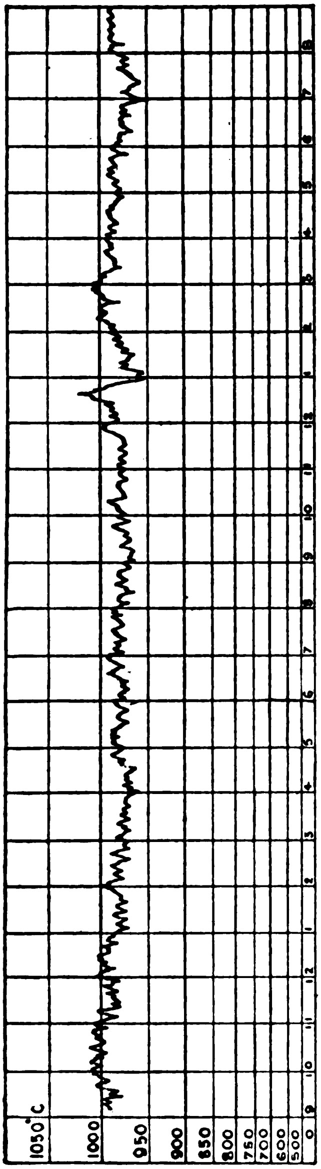

Fig. 16.—Record taken with Féry Pyrometer and Thread Recorder.

We will now pass on to the consideration of the industrial uses of this pyrometer. It may be used in all cases in which the temperature is too high to permit of the continuous employment of an instrument which must be in contact with the source of heat, such as in pottery-kilns, steel-smelting furnaces, glass-kilns, cement-kilns, etc. It can be made to suit any desired range, and has been used to measure such great temperatures as that of the arc-lamp—3,700° C. or 6,700° F.—and is rapid and consistent in its indications. As the secondary principle of the instrument is thermo-electric, records may be taken by means of any good recorder used in conjunction with ordinary pyrometers of this type. Fig. 16 is a sample of such records. The outfit, moreover, is portable, and may be carried from furnace to furnace, which is an advantage over fixed instruments. It is not liable to get out of order with ordinary care, and is easy to use. Care should always be taken, however, to use this pyrometer under black-body conditions, either by sighting the object whilst still in the furnace, or on the end of a closed tube inserted with the end in contact with the source of heat.

The latest development of radiation pyrometers is due to Foster, who has designed an instrument which, within reasonable working limits, gives a correct reading without requiring to be focussed. The action of Foster's fixed-

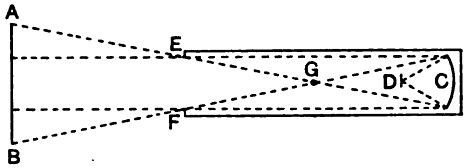

Fig. 17.—Principle of Foster's Fixed-focus Pyrometer.

focus pyrometer will be understood from the diagram (Fig. 17), in which C is the mirror and D the thermal junction, enclosed in a tube with dull, black walls. At the entrance of the tube is an opening, E F, which has sharp edges; and if lines be drawn connecting the extremities of the mirror C with E and F, and produced to the hot substance A B, the same effect on the junction D will be obtained at any distance, provided that the lines G E and G F, when continued, fall on A B. The instrument is so constructed that if A B represent an object six inches in diameter, the same reading will be obtained at any point within five feet of the heated body. As in the Féry pyrometer, a galvanometer graduated in accordance with the fourth-power law is used; and records can similarly be secured with a thermo-electric recorder.

In cases where only a fairly approximate reading is desired, a modified form of Féry's pyrometer may be used, in which the thermal junction is replaced by a bimetallic strip, bent

into a spiral form (Fig. 18), to which a pointer is attached. An increase in temperature causes the spiral to uncoil, and the pointer is thus caused to travel over a scale on which temperatures of the hot source are marked. The general arrangement is the same as that of the Féry pyrometer previously described; and as no galvanometer is necessary, a simplified form of instrument results, the indications, however, being less accurate than those of the ordinary pattern.

So far, we have only considered in this lecture pyrometers based upon the law which governs the total energy radiated. There exists, however, another class of instruments in which an individual ray, selected from the visible part of the spectrum, is made by its intensity to give a

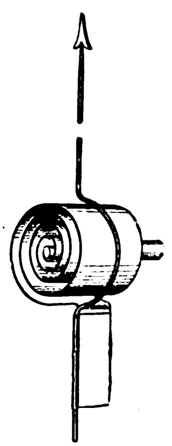

FIG. 18.—SPIRAL USED IN FÉRY PYROMETER (FORM II.).

clue to the temperature of the source. The visible spectrum, obtained when rays from an incandescent source are passed through a prism, represents only a portion of the sifted energy. Beyond the violet end we may trace shorter waves which darken a sensitised paper, and beyond the red are to be found longer waves, which are best detected by absorbing them on a dull, black surface, when they become manifest as heat. The quantitative examination of the spectrum was first undertaken by Tyndall in 1863 by means of the thermopile, which, with its blackened face, converted almost all the rays falling upon it, both visible and invisible, into heat; and by noting the deflection of the galvanometer when the thermopile was placed in different parts of the spectrum, the energy represented by different wave-lengths was discovered. Langley, by the aid of the bolometer—an instrument far more sensitive than the thermopile, and working on the same principle as the resistance pyrometer—was able to map the distribution of energy in the spectrum more accurately than Tyndall; and the combined work of many physicists has resulted in several important generalisations, which have proved of great service in relation to the measurement of temperature. Time will not permit of a description of these valuable investigations, and we shall concern ourselves merely with one of the relations between wave-length and temperature which has been brought to light. It is known as Wein's formula, and is expressed thus:—

$$J = c_1 \lambda^{-5} \times e^{-c_2/\lambda T},$$

where J is the energy due to wave-length λ; T the absolute temperature of the radiating source (a black body); e the base of Napierian logarithms; and c_1 and c_2 constants. This formula is applied in pyrometry by measuring the photometric intensity of a ray in the spectrum—a ray in the red usually being employed. When readings at known temperatures, under black-body conditions, are taken, and the wave-length λ is known, the values of c_1 and c_2 can be determined; and afterwards the absolute temperature T, corresponding to a measured intensity J, can be calculated. Wein based his formula on thermodynamic reasoning from the distribution of energy in the spectrum, and certain points in the investigation are open to objection. Planck has amended the formula by introducing an expression which gives almost identical results with Wein's for short wave-lengths, but different for long. The important fact emerging is that Wein's law, when applied to a red ray from a black body, furnishes a temperature scale identical with that obtained by standard methods, and appears capable of indefinite extension. The temperature of the electric arc, as measured by an optical pyrometer calibrated according to Wein's law, agrees very closely with the figure obtained with a total-radiation pyrometer with a scale calculated from the fourth-power law. We may reasonably conclude, therefore, that the intensity of a portion of the visible spectrum may be employed to give correct readings of the highest temperatures attainable.

Of the several varieties available, I shall select one for detailed description, namely, the Holborn-Kurlbaum optical pyrometer, as this instrument is the simplest, both in construction and use. It consists (Fig. 19) of a telescope, in

the focal plane of which is placed an electric lamp L, furnished with a carbon filament of hair-pin shape, as shown in section at A. In series with this lamp is a battery, a rheostat R, and a milliammeter M, which records the current passing through the lamp. In front of the eye-piece of the telescope two pieces of red glass, D, are placed; and on looking into the telescope a red field, due to the heated object, is seen, upon which the filament of the lamp is superposed. The adjustment consists in altering the resistance R until the filament is brought to the same brightness as the surrounding field, when the current indicated by the milliammeter is read. It would be a somewhat tedious matter to show how readings of current may be translated into temperatures by the aid of Wein's law; and it must suffice to state that a table may be calculated from which temperatures corresponding to milliamperes may be read off. If the temperature of the source exceed that of the lamp at maximum current, the absorbing device E, consisting of two mirrors of dark glass, is placed on the end of the telescope, so that the brightness of the source is reduced below that of the lamp at full current. A second temperature scale is prepared for use with the instrument when the absorber E is employed, and indefinitely high readings can be obtained. One of the advantages of this pyrometer is the ease and certainty of the adjustment; and it may be added that the masterly researches of Waidner and Burgess at the United States Bureau of Standards during the past few years on the highest attainable temperatures, have been conducted by the aid

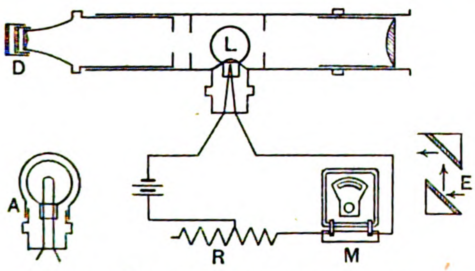

FIG. 19.—HOLBORN-KURLBAUM PYROMETER.

of this instrument. It is manufactured for industrial use in this country by Messrs. Siemens, one form being mounted on a tripod-stand (Fig. 20) for use in a fixed position; whilst a second form (Fig. 21) is made so as to be portable. This pyrometer is of great service for temperatures exceeding 1,200° C., and may be used with equal advantage for lower readings.

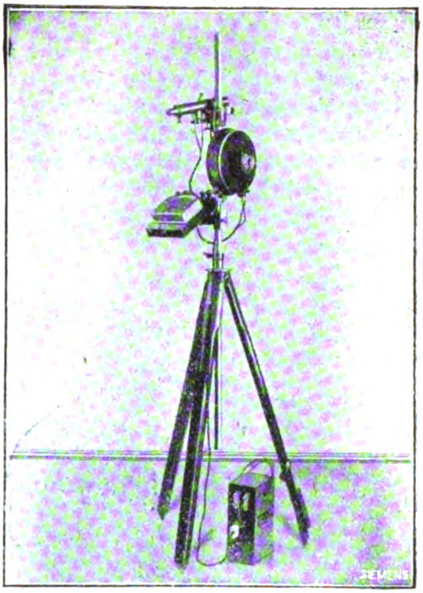

FIG. 20.—SIEMENS' OPTICAL PYROMETER, FOR FIXED POSITION.

(Workshop Form of Holborn-Kurlbaum Pyrometer.)

It cannot be adapted, however, to the taking of records—a defect common to all optical pyrometers.

Several other forms of optical pyrometer are in use, which require in the adjustment the equalising of the colours of two fields, one due to the standard and one to the source; or the production of a special tint. In the Wanner pyrometer red rays from the source and standard are obtained by means of prisms, thus securing monochromatic light, and are brought to equal brightness by a polarising device; whilst in Féry's optical pyrometer rays from the source are passed through two wedges of darkened glass, which are capable of sliding over each other, and are moved until the source is reduced to the same brightness as the standard. Both are capable of calibration by Wein's law. In the Mesuré and Nouel pyrometer, which is a polarising arrangement, the relative brightness of the red and green portions of the spectrum is the principle relied upon, and the adjustment consists in producing a neutral yellow tint by rotating an analyser. The calibration in this case is empirical.

In conclusion, I trust that this course of lectures has made evident the great industrial importance of pyrometry, and will assist in producing an increased appreciation of the value of high temperature measurements. It will

have been gathered that each type possesses advantages peculiar to itself; and the choice of an instrument should always be preceded by a careful consideration of its suitability to the purpose intended. No branch of science better demonstrates the utility of laboratory research in connection with industry; but after all, there exists no real partition between the laboratory and the workshop.

FIG. 21.—SIEMENS' OPTICAL PYROMETER, PORTABLE FORM.

[The following instruments were exhibited:—

(1) A Féry radiation pyrometer, ordinary type, with Thread recorder; (2) A Féry radiation pyrometer, spiral type; (3) A Féry optical pyrometer. By the Cambridge Scientific Instrument Company.

(4) A fixed-focus radiation pyrometer, by the Foster Instrument Company.

(5) Commercial form of Holborn-Kurlbaum Pyrometer, by Messrs. Siemens & Co.

(6) A Mesuré and Nouel pyrometer, by Messrs. A. Gallenkamp & Co.]

BRITISH CAPITAL IN THE UNITED STATES AND THE COLONIES.

In a paper recently read before the Royal Statistical Society, Mr. George Paish gave some interesting particulars relating to the amount of Great Britain's capital investments in the United States and the Colonies. He estimates the total amount of British capital invested in the United States at the enormous sum of £688,000,000. Of this nearly £600,000,000 are in railway securities, £31,500,000 in "finance, land and investment," and £21,500,000 in mines.

After the United States, Great Britain has provided more capital to Canada than to any other country, and the rate at which the British people are now increasing their investments in Canada is extremely rapid. The amount of visible capital our investors have placed in Canada now reaches the great sum of £373,000,000, and new supplies of visible capital are flowing to Canada at the rate of over £30,000,000 a year.

Including the visible capital, says Mr. Paish—that is, the capital privately supplied for loans on mortgage, the purchase of land for the conduct of private businesses, etc.—the amount is probably nearly £40,000,000 a year. The amount of visible capital we have sent to Canada in the last three years has reached £100,000,000. Canada still needs a large sum of money for the completion of the railways now under construction, and inasmuch as the Mother Country is proud of the great progress of her daughter, and is willing to supply her with all the capital she needs to develop her resources, it is evident that our capital investment in Canada will reach a much greater total in a few years. Practically the whole of the capital which has been spent upon railway construction in Canada has been provided by the investors of Great Britain. In the 'nineties, when our investors were suffering from a feeling of distrust of other nations, including the Colonies, the progress of Canada was very slow, and the increase in her population relatively unimportant; but in recent years the ability of Canada to obtain all the capital she needs for the development of her natural riches has stimulated the growth of her population in a wonderful manner.

The British people have provided the Australasian Colonies with nearly as much capital as they have supplied to Canada, the visible amount reaching the great sum of £380,000,000. Of this total, £301,500,000 has been supplied to the Commonwealth, and £78,500,000 to New Zealand. A few years ago the amount of capital supplied to the Australasian Colonies was much greater than that invested in Canada, but the rapidity with which Canada is developing, and the relatively slow progress of the Australasian Colonies have materially changed the situation. In the 'eighties there was a great flow of British capital to Australasia for railway construction, and population increased at a rapid rate; but in the 'nineties the country fell upon misfortune—first, because British investors were not willing to find much new capital in

consequence of their distrust of Colonial and foreign investments at that time; and, secondly, because Australia was visited by a series of droughts which seriously checked her progress. In recent years the credit of Australasia has been fully restored, and the measures that are now being taken to increase the productive power of the country and to develop its natural resources will, doubtless, bring about the influx of a greatly increased amount of capital from this country, and thus stimulate the growth of population and of wealth. Last year the amount of new capital raised in London for Australasia was some £10,000,000. About two-thirds of the capital invested by the British people in Australasia has been provided by loans to the various Governments. The object of these loans was railway construction and other public works. The circumstances of Australasia were such that it was more desirable for the country to use its own credit in order to secure the necessary capital for railway construction than to leave railway extension to private enterprise. In Canada the circumstances are different, and the Canadian people have been able to get all the capital they require for railway construction by means of companies and by private enterprise; but although the methods of obtaining the capital have differed, the railways both of Canada and of Australasia have been almost entirely constructed by means of the capital supplied by the Mother Country.

The investment of the British people in South Africa is also of vast extent. The amount reaches the great sum of £351,000,000. Of this total, £125,000,000 is the capital of mining companies, £97,000,000 loans to the various Governments of South Africa, and £73,000,000 is the capital of land and investment companies. There is a certain amount of duplication in these totals, as the investment companies hold large amounts of mining shares. Although the purely trust companies have been excluded, a certain amount of duplication is unavoidable. Nevertheless the greater portion of the £73,000,000 of capital which we have found for land and investment companies is not duplication, but represents the actual investments of those companies in land and property. This total includes the capital of the British South Africa Company, amounting to £8,250,000. The loans to the Governments have been mainly spent on railway construction, as well as the £9,000,000 of capital which we have supplied to railway companies.

The amount of visible capital we have found for our great Indian Empire is no less than £365,000,000, the larger portion of which has been for the construction of railways. The capital of the railway companies is £137,000,000, and the Government loans of £179,000,000 have been mainly for railway purposes. The capital of tea companies provided by our investors is nearly £20,000,000. No one can doubt the beneficent effect upon the prosperity of India of this expenditure of British capital for the development of the natural resources of the country, and the linking up of district with district, which has so powerfully helped to diminish the severity of famines. This great sum has been lent to India at an exceptionally low rate of interest, and having regard to the immense increase in the wealth of the Indian people which has resulted, and is resulting, from the construction of railways, the burden of the low interest charge is quite negligible. Probably the improvement in the condition of the people resulting from railway construction, has been one of the most potent factors in maintaining the loyalty of the vast populations of India to the British Empire.

The investments of the British people in the minor Colonies are also of a large amount. For West Africa, where the rate of development has recently been rapid owing to the discovery of gold, the British people have found over £29,000,000 of capital, of which £12,000,000 has been for mines and £8,000,000 for Government loans, mainly for railways.

The recent development of the motor-car industry in this and in other countries, which has so greatly increased the demand for rubber, has induced our investors to place considerable amounts of capital in the Straits Settlements and Federated Malay States. The total visible amount of capital we have provided for these Colonies is about £22,000,000, of which over £10,000,000 is for rubber and £8,000,000 for Government loans.

EGYPTIAN CIGARETTES AND TOBACCO.

Egyptian cigarettes are only Egyptian as regards their manufacture. The raw tobacco of which they are made comes almost entirely from Turkey. Greece furnishes a certain quantity of the tobacco imported into Egypt, but most of this is sold by the pound, and is not made into cigarettes in the manufactory, although the poorer Arab purchasers use it to make their own. An attempt was made some years ago to grow tobacco in Egypt, but it was found that only an inferior kind could be produced, the climate not being favourable to the growth of the plant, although it suits the manufacture. The growth and sale of this inferior tobacco encouraged smuggling, so the Government bought all the home-grown tobacco in the Customs and burnt it. The high duty on tobacco in Egypt makes it only worth while to bring the best quality into the country, and whereas the Arab of fifteen years ago, accustomed to the Egyptian-grown weed of inferior flavour or to others equally lacking in good aroma, would contentedly smoke a very poor article, he is to-day much more of a connoisseur. Mr. Matossian, one of the chief cigarette and tobacco manufacturers in Egypt, informed the writer that the inferior leaves in the bales are now re-exported to Hamburg, Bremen, and other towns to fill the cigars manufactured in those places. The poorest Arab now demands something better.

The districts that furnish most of the tobacco imported into Egypt are Samsoun, Bafra, Smyrna, Trebizond, Cavalla, Ismidt, Bulgaria, Bosnia, and

Herzegovina. The import duty is 20 piastres (4 shillings) a kilo. The big firms buy one year's crop for the next year's tobacco and cigarettes. The storage is an art in itself. For instance, certain qualities are not brought into Egypt for many months after purchase, but are left to mature in Turkey, as certain phases of the Egyptian climate would be detrimental to them. Other qualities, when they arrive in Egypt, have to be arranged in a special way, with three or four other bales on the top. Some have to have only one on the top. It depends on the quality and on the maturing required. Thus the immense quantities purchased by a very big firm make it possible, by means of mixture, special packing, acclimatisation, and so on, to keep the quality uniform. Careless, or possibly ignorant packing has sometimes produced spontaneous combustion and caused a serious outbreak of fire.

The first and most important piece of work in cigarette-making is the mixture. The bales are filled with small, flat bunches of tobacco leaves, about a dozen in each. Experts sit surrounded with large baskets, and as each little bunch is untied leaves are distributed into the baskets according to their quality. Speaking generally, the large and golden-coloured leaves belong to the inferior kinds, whereas those to be used for cigarettes are smaller and of duller hue. No smoking is allowed in the manufactories, and they are kept beautifully clean and airy. The air is delicious with the mild, clean fragrance of the best tobacco. Whilst the "mixture" is being made the leaves are gently sprayed with water. The best quality is reserved for the making of cigarettes, other kinds are used for tobacco of different qualities, with which the native makes his own cigarettes.

The next process is the cutting. In very large factories the knife of the cutting machine is worked by machinery and moves with great rapidity, the machine being fed by hand in quantities of several pounds at a time. It is claimed, however, that the best cigarettes of all are those made by the smaller machines in which the knife is worked by the workman and not by machinery. The leaves intended for cigarettes are not chopped so finely as those intended for tobacco to be sold by the pound. English cutlers have so far not been successful in the knives that they have supplied for tobacco cutting. They have not the requisite experience for tempering the steel to the exact requirements of this industry. In a large factory such as Melachrino's, Gianacli's, or Matossian's, where from 1,200 to 1,500 workpeople are employed, there will be perhaps fifteen cutting machines, made for the most part in England, with the exception of the knives. The weighing machines are also of English make. A table with scales is beside each machine and each machine has a revolving counter, that moves very slowly, attached to it. The workman weighs his pounds or half-pounds of tobacco, emptying them into the saucers in the revolving counter. The latter open to let each quantity fall into one of the chain of small tin buckets that the machine circulates. In a direction opposite to that taken by the buckets, rows of glazed and printed papers approach from another part of the machine. At a certain point the tobacco from each bucket is emptied on to a square of paper which is gripped by tweezers under the machine and folded into a packet of tobacco that only requires to be sealed. There are different colours for the different qualities.

Large firms, such as Matossian's, engage in the complete tobacco industry, preparing tobacco to be sold by the pound as well as cigarettes. Many smaller firms engage in cigarettes alone. In the smaller firms each cigarette is made entirely by hand. The paper rolls are made as follows:—Each worker has a small quantity of paste on a clean marble slab. The cigarette papers are folded very deftly round a small wooden ruler, and then fastened with paste at the edges. Practice gives an almost incredible swiftness. As the papers are white, spotless cleanliness in all respects is a necessity. As they are made they are passed, hundreds at a time, to a child at the end of the room, who gives each cigarette case a very slight depression between finger and thumb, to give the correct slightly flattened shape. These are passed on to another set of workers to be filled.

As has been already said, the tobacco for cigarettes has the fibre left much longer than that to be sold by the pound. The method is as follows:—A piece of strong paper, slightly larger than that required for a cigarette case, is fixed at one end to each worker's table. On this he lays about as much tobacco as is wanted for the cigarette, and folds the loose end of the paper round until it takes the form of a cigarette. End to end with this an empty paper case is laid, and then the tobacco (already rolled into the required shape by the fixed piece of paper) is pressed into the empty case by a slender wooden ruler, similar to those used for making the cases. A good worker will fill from two to three thousand in a day, and earn from £2 to £3 a week.

In the large factories machines are now used, which obviate hand labour, but connoisseurs declare that this is no improvement to the smoker. In these the tobacco is put into the machine at one end and slips of paper at the other. At a certain point gum, or some adhesive mixture, drops on to the papers, and at the end a perfectly-made cigarette drops out that only requires clipping at the ends. One of these machines is supposed to do 500 a minute; another guarantees 600, but is worked at 290. Many manufacturers in Egypt have the boxes for their cigarettes made and printed in England. Those for use in Egypt are of cardboard; those for export are of tin. Time is saved in packing boxes by slipping bands of glazed paper round 50 or 100 cigarettes and dropping them into the boxes.

The following list shows the amount of cigarettes exported from Egypt between the years 1906 and

1909, and the customs duty paid in Egyptian pounds. An Egyptian pound is $5\frac{1}{2}d.$ more than a pound sterling.

Year.	Kilos Exported.	Customs Dues.
1906	590,047	£E465,863
1907	452,962	393,503
1908	456,258	364,887
1909	447,222	364,781

The following table shows the countries to which cigarettes were exported and the number of kilos sent to each between January 1st and December 31st, 1909:—

Country.	Kilos.
Germany	108,223
England	79,276
English Possessions in the East	55,169
Austria-Hungary	51,245
Sweden and Norway	46,519
France	31,832
China and Farthest East	29,146
America (United States, 3,979; other Countries, 12,373)	16,352
Belgium	13,107
Switzerland	8,920
Italy	5,414
Holland	7,071
English Possessions in the Mediterranean	2,501
Denmark	617
French Possessions in the Mediterranean	329
Spain	689
Portugal	375
Russia	181
Greece	156
Massana	15
Total	457,232

The export of Egyptian cigarettes to England has fallen off of late years, owing to the high customs duty, but so-called "Egyptian" cigarettes are made in Germany in large quantities, in appearance exactly similar to the genuine article, though very different in aroma.

THE SUGAR-MAKING INDUSTRY IN INDIA.

India is the greatest cane sugar-producing country in the world, but notwithstanding this fact, its sugar market has been captured first by the beet sugar, and later by cane sugar from Mauritius and Java. This condition of affairs has been brought about by the backward state of the Indian sugar-cane industry in the matter of machine appliances. It is estimated that with modern machinery and better organisation of the industry, India could produce 50 per cent. more sugar. Sugar cane is a crop particularly well-suited to the country, and, in the matter of sugar production, India ought to be an exporting rather than an importing country. The native mills are, according to the American Consul in Bombay, either the "kolhu," a mortar and pestle arrangement, in which the cane is bruised and pressed, or else wooden roller mills, of which there are two kinds—the "gundi," consisting of two, sometimes three, upright wooden rollers, and the "belna," used in the Punjab, and made of two horizontal wooden rollers. These mills are made locally, at a cost of from twenty-six to forty shillings. They are hard to work, and do the pressing very ineffectually. In many parts of India these old, clumsy, wooden mills are being replaced by the iron sugar mill. This improvement, however, was only effected after a close study had been made of native ways and requirements, and after the machines had been adapted to these. The cultivators had experienced a great deal of trouble in procuring an efficient machine for crushing purposes, as, owing to their lack of knowledge about machinery, the imported machine soon got out of order, with the result that the cane was imperfectly crushed. Most of the sugar produced in India is consumed in the form of "gur," or unrefined sugar (corresponding to the "Muscovado" of the West Indian planters), because of its adaptability for native sweetmeats and native cookery. The establishment of large central factories has been urged as a means of increasing the sugar yield of the country, and meeting the formidable competition of the imported article. Although there are a few factories of considerable size, most Indian cane is grown and manufactured by small cultivators. Under present conditions the large central factory is hardly practicable. The system of land tenure which obtains practically throughout the country is not adapted to such a system. The soil is divided into a number of small holdings, which produce a variety of crops, according to the fancy of the cultivator. It is practically impossible, therefore, to secure a concentration of sugar plantations around a factory, and so long as cane is only grown in small and isolated patches through a radius of many miles, the cost of handling and carriage, added to the loss of sugar in transit, handicaps the factory so much that success is out of the question. The portable iron mill, therefore, has been found more practical, the cheapness of Indian labour counterbalancing the economies practicable in the large central factories. About half the sugar cane produced in India is grown in the United Provinces. The American Consul states that Mr. W. H. Moreland, Director of Land Records and Agriculture, Lucknow, has given much time and attention to the study of the Indian sugar industry, and would, the Consul believes, be interested to learn of any new crushing machine which would be adaptable to the needs of the Indian cultivator. It is often through the agricultural departments of the various provinces that such things are brought into the country. It is not easy to introduce an article of this description into India, and unless firms are prepared to go to a good deal of trouble, and perhaps some expense, in learning the exact needs of India in respect to such machines, it will be useless to make any such attempt.

RUBBER CULTIVATION IN SOUTHERN ASIA.

The total area devoted to Para rubber plants at the end of 1909 in Malaysia was as follows: Federated Malay States 178,668 acres, Straits Settlements and Kedah 41,405 acres, Johore 28,883 acres, Kelantan 4,111 acres, making a total of 253,067 acres, upon which about 40,000,000 trees are planted. The total number of estates in the Federated Malay States was 377, with an acreage of 500,431. The total number of estates in the whole of Malaysia is 534, with an acreage of 855,992. The total rubber produced in 1909 was, according to the American Consul-General in Singapore, 6,741,509 lbs., an increase of about 100 per cent. over 1908. These are the official returns, but it is believed that the actual output was much greater. In the Federated Malay States rubber estate labourers numbered 77,525 in 1909, while the total number of such labourers in all Malaysia was 110,213. There was no serious disease on the rubber estates in 1909. Root diseases seem the most stubborn, but planters are alive to their dangerous and insidious character. A fungus disease attacking the branch and stem of the trees appeared on some estates, but prompt measures overcame it. White ants still give some trouble, but are no longer considered a serious pest. The business of plantation rubber growing has become the prime factor in the agricultural life of the Malay Peninsula, and naturally the Agricultural and Horticultural Show, held at Singapore in August 1910, made rubber its principal feature. Several buildings were devoted to the display of rubber and rubber machinery, and great interest was taken in this part of the exhibition. The progress of rubber cultivation in Malaysia is remarkable. Six years ago only 13,867 lbs. of rubber were exported. In 1909 the export had increased to 6,741,509 lbs., valued at over two million pounds sterling, and it is believed that the planters have only started in a great rubber era. Since 1902 there has been an upward movement in the price. It was three shillings a pound in 1902, six shillings in 1907, while in May 1910 it reached twelve shillings a pound. As the average cost is about one shilling and threepence a pound to produce and market, the enormous profit, under proper management, is apparent. The probable forty-five million rubber trees ready for "tapping" in 1915 should give a minimum yield of 90,000,000 lbs. Being in the rubber belt the southern islands of the Philippines should be excellent for the industry, and it is predicted that some day great and prosperous rubber estates will be established upon them. Cultivated rubber is still in the experimental stage in Siam. Several plantations have been started by Siamese officials in the States of Singora and Chumpon, and the trees are said to be thriving. In the region of Chantaboon there are many acres under cultivation, and the prospects for the industry there, according to the United States Consul at Bangkok, are encouraging. In the region of Gengkoi, near Korat, there is a considerable extent of land under cultivation. In Patani 58,000 trees are planted in an area of about 300 acres. The total acreage at present under rubber cultivation in Siam is about 3,000. Siam has a vast agricultural area, and only the minutest portion of the soil, which varies in quality from alluvial to mountain lands, has as yet been turned. Labour is comparatively cheap, and since both soil and climate are congenial to the growth of the rubber tree, here is practically an undiscovered country. The Siamese Government realises the possibilities to be derived from opening up the country to the cultivation of rubber, and arrangements are shortly to be made whereby concessions will be granted to intending plantation owners in Siam.

BELGIAN LACE MAKING.

The present number of lace makers in Belgium is stated to be 45,000 women and girls, as compared with 150,000 in 1875. At Turnhout, 2,500 lace makers produce "la dentelle de Malines," a superior article both in design and workmanship, but the majority produce "point de Paris," used for household furnishings, "point de Lille," sold in Holland and Brittany for trimming the characteristic caps worn by native women; "point de Binche," and torchon lace. The lace makers begin their apprenticeship at six to eight years of age, although the legal age limit is nine years. Their hours are from 6.30 to noon and 1 to 7 p.m. in summer, and in winter 8 a.m. to 10 p.m. They earn from fourpence to fivepence a day; the more expert earn sevenpence. The maximum wages paid to the most experienced lace makers never exceed fifteenpence a day, and out of 2,500 workers only about twenty are paid the maximum. Children up to twelve years of age, and even older, are paid tenpence per week. Relatively to its value, the lace workers producing the Malines lace are the most poorly paid. All lace makers are paid by the ell, the Flemish ell being twenty-seven inches. Those working in the schools earn less than those working for a local agent. It is largely due to the existence of intermediaries, or "middlemen," that wages are low. According to the American Consul at Liège, lace schools are either maintained by religious institutions, or are directed by more or less expert lace makers, who gather together the pupils, girls of different ages, in their dwellings, small workmen's houses, added to which are the workrooms into which the children are packed. Often seventy or one hundred workers are crowded into a space that would barely suffice for twenty people to move about in. The rooms are not heated. At nightfall the benches are ranged along the wall, and upon small round tables a petroleum lamp is placed, with flasks of clear water arranged so that the light traverses the water and falls on the lace-pillows of the workers. Lace workers attending these schools pay about fifteenpence per month. The director of a school must turn over all work to

the agent, so that sales in the open market are excluded. All lace produced is offered for sale whether good, bad, or indifferent, a fact that, it is claimed, has depreciated the industry and maintains the low scale of wages that prevails. The lace maker's skill is only developed mechanically, anything like artistic training being lacking, which partly accounts for the large amount of inferior lace found on sale. For improving the condition of the lace workers, and lending support to one of the oldest and most attractive of Belgian industries, a new school has been organised that will consolidate all existing schools and employ those teachers now working separately.

ARTS AND CRAFTS.

Lettering.—One is hardly inclined at first sight to connect a General Election, however remotely, with anything in the way of art. It is natural enough to look upon such an event as productive possibly of all sorts of good and evil results in one way or another, but as regards art (except perhaps the art of caricature) we take it for granted that it has no influence whatever. It would, perhaps, be saying too much to contend that the last election "influenced" art, but there is no manner of doubt that it served to emphasise, and to call attention to, the great strides that have been made in the last few years by a very useful and, until recently, much neglected branch of art. It is only of late that, owing first of all to the efforts of one or two energetic designers and somewhat later to those of a group of enthusiastic scribes, working artists and craftsmen have paid much attention to the subject of lettering. Those who are interested in the matter have noticed how slowly but surely the lettering on posters, advertisements, labels, notices, shop-fronts, and the like, has been improving, but it was left to a large full-page electioneering notice, which appeared in a good many of the newspapers, to bring home to our minds the tremendous gulf which exists between the presentment of such a thing, say ten years ago and to-day. This particular piece of lettering was simple enough, but it compelled attention and was quite undoubtedly, according to the political opinions of its readers, either worthy of the cause it served or deserving of a better one. The fact that this notice was faced in some papers by a counter-announcement, set up in extremely good type, only served to make the advance of taste in lettering more apparent. We can nearly all of us remember a time when notices of this kind would inevitably have been atrocities with which no one would have thought for an instant of associating the word "taste."

It is not only in connection with such flaring things as election announcements, however, that there have been opportunities of late of noticing the growth of taste and care in lettering and typesetting. Anyone on the look out for such things could hardly have failed to note in turning over the leaves of newspapers and magazines the improvement in spacing, setting up, and general arrangement of the publishers' announcements as a whole. Some are a good deal better than others, and one or two have just missed being what they were evidently intended to be, by a little over-effort; but, for all that, they are on the whole a very satisfactory collection.

Another direction in which improvement can easily be traced within the last few years is in the lettering of the street names in certain parts of London, and in the letter-forms, and general arrangement of notice-boards (with the exception, it must be admitted, of those advertising houses to be let or sold, which are almost uniformly unsatisfactory).

At this season of the year, Christmas and New Year cards afford an admirable opportunity of seeing how lettering on a smaller scale is progressing. And in this particular direction the movement cannot be said to be altogether a forward one. Two or three years ago there were some extremely simple cards on the market, consisting entirely of lettering, which were better than such cards were as a rule this year. But, on the other hand, the general standard appears to have gone up. The ordinary private cards printed for people whose taste could at best only be called "negative" or "inoffensive," are decidedly better than they were some years ago, and there is more variety in the kind of lettering employed. There is, too, less of the hideous straggling would-be ornamental current writing which seems to do all in its power to avoid keeping on a straight line. It is rather interesting in this connection to remark that a few of this season's cards were lettered in a way which showed that writers are beginning to remember the old writing-books of the sixteenth, seventeenth, and eighteenth centuries, and to turn to them for inspiration instead of going exclusively to more ancient sources.

Posters.—When we turn to posters, we find that the General Election has played a smaller part than might have been expected in the development of poster design. The space of time which divided this election from the last was so short, and the main political issues so much the same, that the electioneering posters were for the most part old friends, familiar to us all from their appearance on the hoardings only a few months previously. On the whole, the very simple, direct kind of posters after the type of those drawn by Hassall, and other well-known artists, seem to be on the increase, but the type which relies for its effect on a multitude of tints and shades is by no means extinct—indeed, there are more pictures of this sort about still than one would have expected to find, considering the rapidity with which the more direct kind of work appeared to be coming to the fore some years ago. In a few cases, too, it seems as though the advertisers of popular health resorts were returning to the older kind of colour scheme. Some

of these more elaborate posters are certainly effective, but it is the simpler pictures produced in a few vivid, pure colours which on the whole attract, and one might almost say compel, attention.

The lettering on the posters varies very considerably in quality. As a rule it is better than it was some years back. The sloping, highly-shaded inscriptions so common then, are now hardly ever to be seen, at any rate on hoardings in the City and West End (poster design does not show improvement as one travels eastward from Aldgate), but a good deal of the writing is vulgar—and quite unnecessarily so, for a good simple, well-proportioned letter is much more attractive to the eye than an ugly and clumsy one, and distinguishes itself far better from its surroundings. Some of the big railway companies have been advertising their holiday services in very simple but not untasteful fashion, but one of them has a quite hideous announcement which takes one back to the poster designs of twenty or more years ago. Just at the present moment, if it were not for the advertisements of rival electric lamps and of some of the theatres, the hoardings would be rather dull, but it is satisfactory to note that the plan of allowing some plain space between the different announcements, and of giving a certain amount of consideration to the appearance of the advertising space as a whole instead of seeing how many square feet of advertisement can possibly be crammed into it, seems to be still gaining ground.

Trade Bookbindings.—The Christmas season is always a good time for judging of the direction in which general taste is trending as regards trade bookbinding generally—and this Christmas has proved no exception to the rule. It was noticeable that amongst the numerous books got up evidently with a view to the Christmas market there were a great many volumes bound in soft leather and blind stamped—a form of binding which would not have been seen at all a few years ago. The more sumptuous books were, many of them, cased in vellum with a pattern in fine gold lines stamped upon them—and many of these bindings are remarkably satisfactory. Some of them, indeed, were at once so tasteful and so reticent that one was inclined to think at first sight that they were hand-tooled, not because they can be said to ape the hand-work but because the ornament is so much more judiciously used than is often the case with stamped bindings.

Perhaps the most marked feature about this season's book covers is, however, the prevalence of the practice of decorating the front cover with a picture printed on paper by the three-colour process. Some years ago great efforts were made to produce attractive casings by printing on the cloth in light-coloured inks. This was never altogether a success, as the ink had a tendency to thicken, and to produce an unpleasant rather blotted appearance. The effect of a picture printed on paper like an ordinary coloured illustration is, on the other hand, from one point of view, all that could be desired; and these illustrated covers to inexpensive children's books are not only dainty, but quite suitable. Again, to find a well-printed little medallion adorning a modestly got-up white-covered little booklet intended to take the place of a glorified Christmas card in no way shocks anyone's sense of fitness. When, however, a rather gaudy picture is pasted on to the middle of the front cover of a book dealing with a more or less serious subject, and offered for sale at half a guinea or more, one begins to feel that the fashion has gone rather further than is seemly. To begin with, it is artistically by no means an ideal form of decoration for such a purpose; and, to go on with, those of us who still read and who preserve our books with some care are woefully conscious that the appearance of a volume so decorated will probably, after it has been in wear for some years, and has, perhaps, been standing rather closely packed against other books, leave a very great deal to be desired. It is rather a pity that a method of ornamentation which is, for some purposes, quite admirable, should be run to death.

EMPIRE NOTES.

Forest Conservation in Canada.—An important convention, under the auspices of the Canadian Forestry Association, has been summoned by the Prime Minister of Canada, to be held in Quebec from the 18th to the 21st of the present month. The object of the convention is to discuss forestry problems, and particularly the question of conservation. The attention which has been called to the duty of conserving the national resources of the United States and the Dominion by the appointment of a joint commission on the subject, and by the work already done by that body, has resulted in quickening the interest of both Canadians and Americans in the question of their timber reserves. One important result of this movement has been the setting apart of the whole of the eastern slope of the Rocky Mountains by the Canadian Government as a timber reserve, and by the adoption by some of the provincial Governments of regulations dealing with timber cutting and fire ranging, and for the training of foresters. The importance of the forest products of the Dominion may be estimated from the following returns showing the values of the exports for the years 1880, 1890, 1900 and 1909:—In 1880 they amounted to 16,854,507 dollars; in 1890 to 26,179,136 dollars; 1900, to 29,663,668 dollars; and 1909, to 39,667,387 dollars. One of the most striking facts given in the table from which these returns are taken is the large increase in exports to the United States, where the rapid depletion of the spruce, hemlock and poplar supplies has created a good market for Canadian pulpwood. Great Britain has also become a large customer for this Canadian forest product. Of a total import of 427,515 tons of pulpwood in 1909, no less than 107,243 tons came from the Dominion.

It is satisfactory to note, however, that, though the present forest products, used and exported by Canada, are considerable, there are vast areas of timber land which have never been tapped, of which it is estimated that 500 million acres consist of timber suitable for pulp.

The Zoological Gardens and South Africa.—The Zoological Gardens, Regent's Park, will be enriched by a collection of animals representative of the fauna of South Africa, by or before the end of this year. It had been originally intended, by the South African Zoological Society, to present a number of animals to the then Prince of Wales, on the occasion of his proposed visit to South Africa to open the Union Paliament; but, owing to the alteration of the plans necessitated by the lamented death of King Edward, the matter fell into abeyance for the time. The visit of H.R.H. the Duke of Connaught has, however, revived the proposal, so that the original intention will now be carried into effect, under an influential committee, representing the various provinces of the Union. Some rare birds, including a pair of the largest and rarest bustards known, have already been sent to London, and a pair of lion cubs, presented to the Duke of Connaught, which will form part of the collection, are expected to arrive in a few weeks. There is no doubt, from the interest which is being taken in the subject in South Africa, that a very valuable collection will be got together, which will form an interesting souvenir of the Union, and be a considerable attraction to the Gardens.

East Africa Wheat Supply.—In estimating the value of the Empire's sources of food supplies, it is gratifying to hear that East Africa expects to be able, within the next few years, to export a considerable surplus of wheat for the home market. The area under wheat cultivation in the Protectorate is rapidly extending, and is now nearly sufficient to meet all the requirements of the country itself. Samples of the wheat, examined and tested at the Imperial Institute, show that they would command a ready sale in the United Kingdom at prices comparing favourably with the finest description of imported grain. It has been found, too, that edible beans grown in East Africa may find a good market here, especially "haricot" and "butter" beans, while other varieties have proved equally satisfactory for cattle food.

The United States and Canadian Immigration.—In a recent report to Congress, the Chairman of the United States Immigration Commission compares the statistics of immigration into Canada during the last ten years with those of the United States, and he says that, while 70 per cent. of Canada's immigrants for that period came from Northern and Western Europe, and only 30 per cent. from Southern and Eastern Europe, it was the reverse with the United States. He states also that, during the last three years, more than seven-eighths of the emigrants from the States to the Dominion were classed as farmers or farm-labourers. Further, he shows that, from 1900 to 1909, of 225,690 homesteads taken up in Western Canada, 44·91 per cent. were applied for by settlers from the United States, 20·32 per cent. from England, 5·20 per cent. from Scotland, 1·89 per cent. from Ireland, and 27·07 per cent. from Continental Europe. These facts are of great interest, and show that the United States authorities are alive to the comparatively high quality of the immigrants which Canada is receiving. A further interesting comparison is furnished in a report of Mr. J. Obed Smith, the Assistant Superintendent of Emigration in this country, who states that, in the first ten months of this year, the number of emigrants from the United Kingdom to Canada was 149,420, as against 121,273 to the United States, while, for the same period last year, the numbers were 80,888 and 99,603 respectively. This is satisfactory, as, however cordial may be the relations between this country and the United States, it is certainly desirable, from an Imperial point of view, that British emigrants should settle in British lands.

The Financial Outlook in South Africa.—The Union Government enters upon its first financial year with excellent prospects, as, although the Minister of Finance anticipates a deficit of £1,451,000, there is a surplus of £1,220,000 from the railways, which he has decided to appropriate. This amount, and the amount realisable from the extension of the 10 per cent. Transvaal gold mines tax to the diamond mines of Kimberley and the Orange Free State, will, it is estimated, supply him with £9,000 over the balance. This is certainly most satisfactory, and well justifies the confidence of the new Government in their financial position. The question of the consolidation of the debts of the various provinces will, it is understood, very early occupy the attention of the Finance Minister, since, unlike the Australian Commonwealth, which "may" take over the debts of the Federal States, the Union Government of South Africa must do so. But although difficulties will have to be faced, there is no doubt that the result will be greatly to the advantage of the country.

The Exhibition at Allahabad.—At the opening of the United Provinces Exhibition at Allahabad on December 1st, 1910, Sir John Hewett, referring to the Agricultural Court, characterised it as the most important feature of the Exhibition, and drew special attention to the display of agricultural machinery, which he regarded as opportune, in view of the advance of wages in the provinces, which naturally causes landholders and large cultivators to adopt labour-saving implements. "It is a matter of special satisfaction," he said, "that many large manufacturing firms have realised the importance of this great undeveloped market, and, not content with exhibiting their standard machines, have spent much time in designing machines specially suited to the peculiar

conditions of the country." But, while he spoke highly of the exhibits, he urged the necessity of manufacturers and their agents following up the work which the Exhibition had so well begun. "Agencies," he stated, "in the distant cities of Calcutta and Bombay have not, as yet, the local knowledge of the local resources required to develop the market of Northern India, nor can they maintain the close touch with the Government agricultural departments, which is so necessary to success in the early stages of the campaign." It is satisfactory to know that the exhibitors, among whom are representatives of some of the leading British manufacturers of agricultural implements, have endeavoured, so far, to meet "the peculiar conditions of the country," but there is doubtless great wisdom in the suggestion that the Exhibition should be regarded only as a starting point, and that, to realise the full advantage which the agricultural development of the Northern Provinces offers, the work must be diligently followed up.

Tasmanian Mining.—It is reported that a valuable discovery of mineral-bearing country has been made in the area of the Stanley River Tinfield, Tasmania. A rich lode had previously been found at Mount Lindsay, a spur of the Parson's Hood Range. This lode shows 4 feet of ore, estimated to carry 30 per cent. of tin, and a formation 60 feet in width, which is highly stanniferous. But this find has been dwarfed by a report stating that there is a stretch of country, some 600 feet wide, running north-west and south-east, which carries gold, copper, and tin. The formation has been proved to extend over half a mile in length, and, at the height of about 400 feet, carries a saddle into the Wilson Watershed at Stanley River. The formation is said, for the greater part, to consist of mica, containing a large percentage of tin, and offers little or no difficulty in treatment. This discovery will strengthen the Government in their resolution to provide better means of communication for the district, by which the Stanley Reward and other mines in the neighbourhood may be profitably developed.

GENERAL NOTES.

BOOKS OF THE YEAR.—According to the *Publisher's Circular*, the total number of books published in this country during the year 1910 is 10,804, showing an increase of 79 on the total for 1909, in spite of the occurrence of two General Elections and the lamented death of His Majesty King Edward VII. The returns have been analysed as follows:—(1) Religion, Philosophy, etc., 1,064; (2) Educational, Classical and Philological, 659; (3) Fiction, Juvenile Works, etc., 2,833; (4) Law, Jurisprudence, etc., 248; (5) Political and Social Economy, Commerce, etc., 816; (6) Arts (fine and useful), Sciences, etc., 1,254; (7) Voyages, Travels, etc., 604; (8) History, Biography, etc., 860; (9) Poetry and Drama, 590; (10) Year Books and Serials in Volumes, 488; (11) Medicine, Surgery, etc., 398; (12) Belles Lettres, Essays, etc., 272; (13) Miscellaneous (including Pamphlets), 718.

A GREAT SUGAR ESTATE.—It is not perhaps generally known that one of the finest sugar plantations in the world is in Colombia. The Ingenio, Central Colombia, as Mr. Pro-Consul Stevenson shows in his report on the trade and commerce of Cartagena just published (No. 4,617 Annual Series), is not inferior to the very best estates of Cuba. It is situated in Sincerin, about twenty-eight miles distant from Cartagena, and along the Dique Canal, connecting this port with the River Magdalena. The first *zafra* (crop) of 1909-10 produced 5,082 tons of sugar, of which 1,903 tons were exported to the United Kingdom and 1,304 tons to New York. Early rains spoiled a large portion of cane plantations, or the production would have been much greater.

COTTON CULTIVATION IN EGYPT.—The Financial Adviser to the Egyptian Government has just issued a note on cotton cultivation which, on the whole, is encouraging. He anticipates that the total crop will exceed 6,750,000 cantars which, on the basis of the high prices prevailing, represents a sum accruing to the country much in excess of any recently recorded. The causes which, on the one hand, produced the very small crop of 1909, and, on the other, the relatively good results of 1910, remain obscure, but it is probable that the active measures undertaken by the Government against the cotton worm, the urgent recommendations given to the cultivator against excessive watering, the late flood, and the favourable autumn weather, have all contributed to the improved results. But there remains an unknown quantity as a factor in the situation of the two years, and it is necessary that the study of the various conditions affecting the cotton plant, which has now been seriously begun, should be carried on as actively as possible. An agricultural department is in course of formation, and a director-general has been chosen with wide experience of the subject with which he will have to deal.

TECHNICAL COURSES AT THE L.C.C. CENTRAL SCHOOL OF ARTS AND CRAFTS.—The following courses of lectures will be given at the London County Council Central School of Arts and Crafts, Southampton Row, W.C.:—On Silversmithing Subjects, on Tuesdays, January 10th, 17th, 24th, 31st and February 7th, by Messrs. J. Starkie Gardner, H. Wilson, G. A. Fournier and B. J. Tully; on Ancient and Modern Jewellery, on Fridays, January 13th and February 10th, by Mr. H. Wilson; on Book Production Subjects, on Wednesdays, January 11th, 18th, 25th and February 1st, 8th and 15th, by Messrs. Edward Johnston, R. W. Sindall, F.C.S., C. I. Smyth and Dr. J. Gordon Parker. The lectures will begin at 8 p.m., and members of the trades concerned are invited to attend.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

January 18.—John C. Medd, M.A., "The Dutch Labour Colonies." Lord Reay, G.C.S.I., G.C.I.E., will preside.

January 25.—Horace M. Wyatt, "Motor Transport in Great Britain and the Colonies."

February 1.—Philip Joseph Hartog, M.A., B.Sc., "Examinations and their bearing on National Efficiency." The Earl of Cromer, G.C.B., O.M., G.C.M.G., K.C.S.I., C.I.E., Vice-President of the Society, will preside.

February 8.—Captain A. J. N. Tremearne, B.A., D.Anth., "Some Nigerian Head-Hunters."

February 15.—George A. Stephen, "Modern Machine Book-binding." John Murray, J.P., D.L., F.S.A., will preside.

February 22.—Professor J. Wertheimer, B.Sc., B.A., "Water-Finders."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

January 19. — Reginald Murray, formerly Manager, Chartered Mercantile Bank of India, London and China, in the Straits Settlements and India, "Banking in India." Sir Felix Schuster, Bart., will preside.

February 9.—R. A. Leslie Moore, I.C.S. (retd.), "Indian Superstitions."

March 16, April 27, May 25.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

January 31.—F. Douglas Osborne, M.Inst.M.M., "The Tin Resources of the Empire."

February 28.—The Hon. Sir Richard Solomon, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "The Resources and Problems of the Union of South Africa."

April 4.—Captain R. Muirhead Collins, C.M.G., "Australia and her Resources."

May 9.—F. Williams Taylor, "Canadian Banking."

Cantor Lectures.

Monday Evenings, at 8 o'clock:—

Frederick Wedmore, "Etching." Two Lectures.

Syllabus.

Lecture I.—January 23.—"The Old Masters." The Cradle of great Etching—Rembrandt's place—Ostade and Bega—Vandyke—Landscape and Animal Subjects in the Low Countries—The Classic Landscape — Claude — Links with the Moderns—Etching no "Minor Art."

Lecture II.—January 30.—"Modern Etching." Goya—Wilkie and Geddes—The Silence before the Revival—The great French Outburst—Méryon, Bracquemond and Jacquemart — Haden and Whistler—Themes mainly Landscape, Portraiture, Architecture—The Etching of To-day.

Professor Adrian J. Brown, M.Sc., "Brewing and Modern Science." Four Lectures.

Syllabus.

Lecture I. — February 6. — Introduction. Dr. Graham's Lectures Thirty-seven Years Ago—The Brewing Process a succession of Complex Biochemical Changes—Barley: Classification of types used by the Maltster—Barley from the Agriculturist's and Brewer's Points of View—Present Position of Knowledge regarding Characteristics of Malting Barley—Results of recent Experiments on Barley Cultivation in Ireland, etc.

Lecture II.—February 13. — "Malting." Constitution of the Barleycorn — Character of Changes during Germination—Investigations of the Biochemistry of Germination—The Barleycorn a highly-specialised seed, etc.

Lecture III.—February 20.—"The Mashing Process." The Chemistry of Starch and its Transformation Products—Protein Changes during the Mashing Process.

Lecture IV.—February 27.—"The Fermentation Process." Previous Treatment of the subject by Dr. G. Salamon in 1888—The Pure Yeast Question in Brewing—Zymase and Modern Views of Alcoholic Fermentation—Nitrogen Assimilation—The so-called "secondary" products of Fermentation, etc.—Conclusion.

Professor J. A. Fleming, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

March 6, 13, 20, 27.

Alfred E. H. Tutton, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

Dates to be hereafter announced:—

Frank M. Andrews, "Architecture in America."

Arthur Charles Davis, F.C.S., Assoc.Inst.C.E., "The Manufacture and Testing of Portland Cement."

George B. Heming, "Art Education in Jewellery and Goldsmithing."

Colonel Charles Edward Cassal, V.D., F.I.C., "The Adulteration of Food."

Dr. Leonard Hill, F.R.S., "Caisson Sickness and Compressed Air."

Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

Hal Williams, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

Noel Heaton, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

Sir Thomas Henry Holland, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord Avebury, D.C.L., LL.D., F.R.S., will preside. (Indian Section.)

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 16...Illuminating Engineers, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Discussion on Library Lighting, to be opened by Mr. J. D. Brown (Islington Public Library) and Mr. S. L. Jast (Croydon Public Library).

Bibliographical, 20, Hanover-square, W., 5 p.m. 1. Annual Meeting. 2. Mr. R. Steele, "Some Sixteenth Century English Books with Spurious Imprints."

Engineers, Junior Institution of, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. L. W. J. Costello, "The Law Relating to Engineering." (Lecture V.)

Geographical, Burlington-gardens, W., 8.30 p.m. Sir John Murray and Dr. Hjort, "The 'Michael Sars' North Atlantic Deep-Sea Expedition."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. Halsey Ricardo, "Cardinal Medici's Pleasure House."

London Institution, Finsbury-circus, E.C., 5 p.m. Bishop Welldon, "Some Thoughts Suggested by Travel over the Empire."

TUESDAY, JANUARY 17...Royal Institution, Albemarle-street, W., 3 p.m. Professor F. W. Mott, "Heredity." (Lecture I.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on papers by Mr. William Dawson, "The Strengthening of the Roof of New Street Station, Birmingham," and "The Reconstruction and Widening of Arpley Bridge, Warrington."

Statistical, at the ROYAL SOCIETY OF ARTS, John-st., Adelphi, W.C., 5 p.m. M. Armand Julin, "The Economic Progress of Belgium from 1880 to 1908."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. Max Poser, "High Power Photo-micrography."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Mr. W. H. Garrison, "Our World-wide Empire."

WEDNESDAY, JANUARY 18...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. John C. Medd, "The Dutch Labour Colonies."

Meteorological, 25, Great George-street, S.W., 7.30 p.m. 1. Annual Meeting. 2. Address by the President (Mr. Henry Mellish), "The Present Position of British Climatology."

Metals, Institute of, at the Institution of Mechanical Engineers, Storey's-gate, Westminster, S.W., 10.30 a.m. Annual Meeting. 1. Professor H. C. H. Carpenter, "A New Critical Point in Copper-Zinc Alloys: Its Interpretation and Influence on their Properties," with an Appendix on "The Nature of Solid Solutions," by Mr. C. A. Edwards. 2. Engineer Rear-Admiral J. T. Corner, "Some Practical Experience with Corrosion of Metals." 3. Mr. H. J. Humphries and Professor C. A. Smith, "Some Tests on White Anti-Friction Bearing Metals." 4. Professor A. McWilliam and Mr. W. R. Barclay, "The Adhesion of Electro-Deposited Silver in Relation to the Nature of the German Silver Basis Metal." 5. Mr. G. D. Bengough, "Preliminary Report to the Corrosion Committee."

Microscopical, 20, Hanover-square, W., 8 p.m. Annual Address by the President, Professor J. A. Thomson.

Entomological, 11, Chandos-street, W., 8 p.m. Annual Meeting.

United Service Institution, Whitehall, S.W., 3 p.m. Mr. D. Owen, "The Declaration of London and Our Food Supplies."

THURSDAY, JANUARY 19...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. Reginald Murray, "Banking in India."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m.

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. W. H. Hurtley and W. O. Wootton, "The Interaction of Alloxan and Glycine." 2. Messrs. T. P. Hilditch and S. Smiles, "Intramolecular Rearrangement of Diphenylmethane o-sulphoxide." 3. Mr. V. H. Veley, "The Reactions between Chemical Compounds and Living Muscle Proteins." 4. Messrs. P. C. Ray and H. K. Sen, "The Decomposition Products of Tetra-methyl Ammonium Nitrite under Heat." 5. Mr. P. C. Ray, "Retardation and Acceleration in the Dissolution of Mercury in Nitric Acid in Presence of Minute Quantities of Ferric Salts and Manganese Nitrate." 6. Messrs. W. N. Haworth, W. H. Perkin and O. Wallach, "On dl- and d-Δ^2-m-menthenol (8) and dl- and d-$\Delta^{2,8(9)}$-m-menthadiene." 7. Miss B. Dobson and Dr. W. H. Perkin, "The Identity of Xanthaline with Papaveraldine." 8. Mr. R. A. Joyner, "Amalgams containing Silver and Tin." 9. Mr. R. C. Bowden, "Studies of the Constitution of Soap in Solution: the Electrical Conductivity of Sodium Stearate Solutions." 10. Messrs. J. J. Sudborough and S. H. Beard, "Additive Compounds of Phenols and Phenolic Ethers with Polynitro-aromatic Derivatives." 11. Mr. T. P. Hilditch, "The Effect of Contiguous Unsaturated Groups upon Optical Activity." 12. Mr. E. P. Perman, "The Direct Action of Radium on Ammonia." 13. Mr. S. U. Pickering, "Cupritartrates and Analogous Compounds."

Humanitarian League, Caxton Hall, Westminster, S.W., 8 p.m. Mr. James Buckland, "The Birds of our Colonies and their Preservation."

London Institution, Finsbury-circus, E.C., 6 p.m. Dr. R. D. Roberts, "The Grand Canyon of the Colorado."

Royal Institution, Albemarle-street, W., 3 p.m. The Astronomer-Royal, "Recent Progress in Astronomy." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Cinematographic Exhibition of Living Micro-organisms.

Historical, 7, South-square, Gray's Inn, W.C., 5 p.m. Miss J. Dunlop, "Early Apprenticeship in England."

Numismatic, 22, Albemarle-street, W., 6.30 p.m. Mr. G. F. Hill, "Classical Influence on the Medals of the Italian Renaissance."

Philatelic, 4, Southampton-row, W.C., 6 p.m. Display of the Pictorial Issues of New Zealand.

FRIDAY, JANUARY 20...Royal Institution, Albemarle-street, W., 9 p.m. Professor Sir James Dewar, "Chemical and Physical Change at Low Temperatures."

Mechanical Engineers, Storey's Gate, Westminster, S.W., 8 p.m. Messrs. Walter Dixon and George H. Baxter, "Modern Electrical Dock-Equipment, with Special Reference to Electrically-operated Coal-Hoists."

Civil Engineers, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. G. F. Walton, "The Design and Construction of Reinforced-Concrete Arches."

SATURDAY, JANUARY 21...Royal Institution, Albemarle-st., W., 3 p.m. Mr. Arthur Hassall, "Problems in the Career of the Great Napoleon." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,035. VOL. LIX.

FRIDAY, JANUARY 20, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 23rd, 8 p.m. (Cantor Lecture.) FREDERICK WEDMORE, "Etching." (Lecture I.—"The Old Masters.")

WEDNESDAY, JANUARY 25th, 8 p.m. (Ordinary Meeting.) HORACE M. WYATT, "Motor Transport in Great Britain and the Colonies." The Hon. RICHARD CLERE PARSONS, M.A., Vice-President of the Society, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

"OWEN JONES" PRIZES FOR INDUSTRIAL DESIGN.

The Council of the Royal Society of Arts hold a sum of £400, the balance of the subscriptions to the Owen Jones Memorial Fund, presented to them by the Committee of that fund in 1876, on condition that the interest thereof be spent in prizes to "Students of Schools of Art who, in annual competition, produce the best designs for Household Furniture, Carpets, Wall-papers and Hangings, Damasks, Chintzes, etc., regulated by the principles laid down by Owen Jones."

Competitions, under the terms of this Trust, have been held annually since 1878.

The next award will be made in 1911, when six prizes are offered for competition, each prize to consist of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the "Grammar of Ornament," by Owen Jones, and the Society's Bronze Medal.

The prizes will be awarded on the Report of the Examiners in the National Competition of the Board of Education. The designs must be submitted in the usual manner to the Board of Education by April 1st, 1911. They must be marked "In competition for the Owen Jones Prizes," and must comply with the regulations of the Board of Education. The exact address to which the works should be sent will be communicated to the schools later on by the Board of Education.

No candidate who has gained one of the above prizes can again take part in the competition.

Since the institution of the above competition in 1878 six prizes have been awarded annually, except in the year 1879, when three prizes only were offered.

Of the 195 prizes which have been awarded, Macclesfield School of Art has taken 33, the first award having been made in 1881, and, with only five intervals of one year each, and one interval (1889–1892) of four years, the School of Art of that town has appeared in the prize list each year since—in several instances two awards being gained, whilst in 1909, five out of the six prizes offered were awarded to students of this school. In 1910 the number of prizes gained by them was three.

Manchester (Cavendish-street School of Art) first appeared in the list for 1879, and from 1883 till 1893 was included amongst each year's successful schools—generally with two, twice with three, and once (1886) with four prizes to its credit. In 1895 and 1896 one award in each year was gained. Then there was an interval till 1901, with one award in that year. The name did not appear again in the list of successful schools till 1907 (one prize), 1908 (two prizes), and 1910 (one prize). Manchester thus obtained in all 30 awards.

London Schools of Art have amongst them taken 30 prizes, the first award being gained in 1879, and the last one in 1910. Of the total

successes. Battersea School of Art has gained 14—its first appearance in the lists being in 1895, and the last in 1905.

The remaining London awards are distributed among the following Schools of Art:—

Bloomsbury	1
Birkbeck	1
Chelsea	3
South Kensington	5
West London	5
Westminster (St. Mary's)	1

Glasgow School of Art has received 24 awards, commencing in 1882, and it continued to appear in the list nearly every year till 1903, when the last award was gained.

Nottingham School of Art, starting in the first year of the competition (1878) with four prizes, has 14 awards to its credit—the last being in 1908.

Of the 195 awards made since the first offer of the prizes, 131 have been gained by students of Schools of Art in the above five centres.

The remaining 64 awards are divided between 28 centres in the proportions given below:—

Leeds	7	Kidderminster	2
Hertford	6	Leicester	2
Coalbrookdale	5	Salisbury	2
Canterbury	5	Barnsley	1
Carlisle	4	Derby	1
Northampton	3	Dundee	1
Scarborough	3	Durham	1
Bath	2	Glossop	1
Birmingham	2	Halifax	1
Bradford	2	Sheffield	1
Burnley	2	Shipley	1
Dover	2	Stroud	1
Dublin	2	Sunderland	1
Huddersfield	2	Warrington	1

In the year 1909, 192 competitors submitted 481 works for competition, whilst in the year 1910, 441 works from 164 competitors were considered by the Examiners.

In their report for 1910 the Examiners state: "Among the 441 works sent in for this competition were a number of designs without any merit whatever; some were so bad as to be unfit for submission in any competition, a considerable number of these coming from one school. The most successful attempts were found among the Woven, Printed, and Stencilled Fabrics. The Designs for Furniture were not thoughtfully considered from the point of view of the principles laid down by Owen Jones. There were some promising specimens of Tiles, Plaster work, and Embroidery."

PROCEEDINGS OF THE SOCIETY.

SIXTH ORDINARY MEETING.

Wednesday, January 18th, 1911; The Right Hon. Lord REAY, G.C.S.I., G.C.I.E., LL.D., in the chair.

The following candidates were proposed for election as members of the Society:—

Armsby, Henry Prentiss, Institute of Animal Nutrition, Pennsylvania State College, State College, Pennsylvania, U.S.A.

Beaumont, Frederick, 6, William-street, Lowndes-square, S.W.

Bebb, Charles H., Denny Building, Seattle, Washington, U.S.A.

Blain, Alexander W., M.D., 1105, Jefferson-avenue, Detroit, Michigan, U.S.A.

Chirol, Valentine, Queen Anne's-mansions, Westminster, S.W.

De Wardt, John Isaac, 82, Pelham-road, Gravesend.

Dowding, J. C., Chinwangtao, North China.

Eyde, Sam, Sommerrogaden 15, Christiania, Norway.

Fahy, John Thomas, A.M.I.E.E., New Zealand Railways, Wellington, New Zealand.

Finn, Herbert J., 23, Sandgate-road, Folkestone; and c/o The Modern Gallery, 61, New Bond-street, W.

Flower, Charles E., Warborough, near Wallingford, Oxon.

Hogg, Rev. William Charles, 116, East Third-street, Williamsport, Pennsylvania, U.S.A.

Kakting, Robert, c/o Messrs. O. W. Lindholm & Co., Vladivostock, Siberia.

Kean, Athelstan Joseph Alexander, P.O. Box 50, Guanajuato, Guanajuato, Mexico.

Lord, William Henry H., A.R.C.A.(Lond.), 24, The Pavement, Clapham Common, S.W.

Mackenzie, Roderick D., 9, St. Paul's Studios, Colet-gardens, West Kensington, W.

Martin, Miss Cicely Bridget, 3A, Church-road, Upper Norwood, S.E.

Menzies, Dr. F. N. Kay, 79, Davies-street, Berkeley-square, W.

Millar, Alex. H., LL.D., F.S.A.(Scot.), Rosslyn House, Clepington-road, Dundee.

Millar, F. Grahame, Tangga Batu Estate, Malacca, Straits Settlements.

Newman, Miss Florence, Garlinge, 14, Templar's-avenue, Golder's-green, N.W.

Pannett, Robert Elliott, J.P., Whitby, Yorkshire.

Peat, William Barclay, F.C.A., 11, Ironmonger-lane, E.C.

Powelson, W. V. N., 60, Wall-street, New York City, U.S.A.

Quinton, Alfred R., Westfield, Salisbury-avenue, Church End, Finchley, N.

Sunder, Donald Herbert Edmund, F.L.S., c/o Messrs. Grindlay & Co., Calcutta, India.

Tatlock, Miss H. H., 16, Park-square, Regent's-park, N.W.; and Bramfield House, Halesworth, Suffolk.

Tower, His Excellency Reginald T., C.V.O., Traveller's Club, Pall Mall, S.W.

Waley, Alexander Simon, 32, Rue Spontini Avenue du Bois de Boulogne, Paris, France.

Westervelt, William Young, 100, William-street, New York City, U.S.A.

Whittemore, Harris, Nangatuck, Connecticut, U.S.A.

Youngman, Miss A. M., R.I., Porton, Salisbury, Wilts.

The following candidates were balloted for and duly elected members of the Society:—

Andrews, Neale, Oak Works, Church-road, Hanwell.

Chamberlain, Frederick, 23, Herbert-street, West Bromwich.

Chater, Cecil William, Assoc.Inst.M.M., c/o Messrs. Mower & Co., Rangoon, Burma.

Clarke, Miss Alice Dolores, 24, The Grove, Boltons, S.W.

Hedley, Perceval Manfred Florance, The Studio, 16A, Soho-square, W.

Kiralfy, Charles I., 141, Holland-road, W.

McClean, William Newsam, 63, Evelyn-gardens, S.W.

Marlow, Thomas Gibbons, 138, Telford-avenue, S.W.

Merrick, William Altwicker, 5, Carlisle-street, Marylebone, W.

Smith, Samuel Joseph Woodham, 30, Fleet-street, E.C.

The paper read was—

THE DUTCH LABOUR COLONIES.

By John C. Medd, M.A.

Before commencing to read this paper it is fitting that I should refer to the great loss which the advocates of Labour Colonies have sustained by the death of Mr. S. H. Butcher. It was my privilege to know him intimately, and if any man can honestly say, "*Homo sum: humani nihil a me alienum puto,*" Mr. Butcher was such a man. Like every thoughtful statesman, he was constantly oppressed by the vast amount of suffering occasioned by unemployment, often preventable or capable of remedy, and notwithstanding his multifarious activities studied the question very thoroughly. He felt that temporary measures of relief, which, as a rule, perpetuate instead of eradicating the evils, avail little, and that some definite steps towards permanently lessening the volume of unemployment are essential. This led him to give his weighty support to the scheme for establishing Colonies in England upon the model of those in Holland, and he was amongst the first to sign the memorial to Mr. John Burns and Lord Carrington upon the subject last year. The fact that he and other Unionists should have done so emphasises the absolutely non-political character of the movement, while it disposes of the assertion that it has any Socialistic tendency. It is still argued in certain quarters that the creation of such Colonies as are suggested implies that the right to work is a legitimate demand, and ought to be satisfied. Even if that be the case, where is the objection? The principle of the right to work has been already admitted in much recent legislation, and is in accordance with the recommendation of the Poor Law Commission of 1834, that an offer of useful work, under conditions less eligible than those of the life of an ordinary labourer, should be placed within reach of any destitute, able-bodied man who desired to accept it. There must be something fundamentally wrong in the industrial organisation of a State when men physically fit and anxious for employment are unable to find it. To maintain that it "would necessarily impair the national efficiency and lower the national standard," is to ignore the situation as it actually presents itself. Thousands of men strong in mind and body, are, from circumstances beyond their control, out of employment; and few will deny that it is a proper function, as well as to the interest, of the State to devise means whereby they may be rescued from their enforced idleness with its inevitable deterioration and temptations.

The efforts hitherto in this country to solve the problem have not proved either an economic or an industrial success. This was the unanimous conclusion of the Poor Law Commissioners. The whole history of the past has been vitiated by a policy devoid of any well-defined object, by misguided philanthropy and by the failure to distinguish clearly between the unemployable and those genuinely in search of work. To take one instance only—the circular letters issued by the Local Government Board in 1886 and 1895 were, as was recently pointed out by Mr. Loch, a fatal step, through making the vestries and borough councils partially recognised relief authorities concurrently with the Poor Law. The local authorities rarely possessed any specific knowledge or experience to guide them; the work was badly done and at a ruinous cost. Year after year the same people, drawn mainly from the habitually unemployed,

applied for relief. Enormous sums of money have been expended without visible result—notably, by the London (Central) Unemployed Body, the members of which were admittedly not conspicuous for any business capacity, familiarity with trade conditions or knowledge of the idiosyncrasies and requirements of labourers in general. The value of their experiment at Hollesley Bay is extremely doubtful. Innumerable changes have taken place there, but the imperative necessity for prolonged and uninterrupted training at the Colony is not yet realised. The type of men usually admitted cannot be rehabilitated within two or three months; the average period of residence, however, is only about 12·2 weeks per man. Sufficient time has not elapsed for estimating the results of what is being done by the Distress Committees in London and elsewhere, since they acquired a statutory position under the Unemployed Workmen Act of 1905.

In its widest aspects the problem is purely urban. To whatever extent unemployment may be caused by periodical trade depressions, or by the fluctuating and seasonal demand for labour in certain trades—such as building, etc.—it is chiefly due to the congested condition of our cities. I may mention, incidentally, that the United States have to deal with much the same problem. The other day a letter was forwarded to me from a gentleman, who has recently been appointed a member of the State Commission in New York to inquire into and report upon the distribution of congested city population in rural districts, asking for information as to the methods adopted here. At the beginning of the last century the urban population of England was computed at 30, and the rural at 70 per cent.; in the middle of the century the percentages were about equal; at the last census 77 per cent. were urban and 23 per cent. rural, and to-day the ratio is probably at least 80 to 20 per cent. In France, on the other hand, where there is also a steady migration to urban centres, more than 45 per cent. of the total population are engaged in some branch of agriculture. The tendency to desert the countryside is world-wide in its operations. It may be checked, but it cannot be stopped, nor would it be desirable to stop it, even if it were possible, for the towns have to rely upon a regular supply of fresh and vigorous material from the villages. Every one admits the necessity of repopulating the rural districts, but it is futile to imagine that men inured to city life and of enfeebled constitution can be immediately transplanted there with any benefit to themselves or their employers. "Philanthropic ruralism can effect very little," and a year or two ago the Bureau of Agriculture at Washington published an emphatic warning against the folly of inducing men indiscriminately to revert to the land—a warning which is equally needed here. Nor can the afforestation recommendations of the Coast Erosion Commission be seriously entertained as a solution of the problem. The cost is prohibitive, and the men on whose behalf the suggestion is made are rarely of a physique capable of undertaking the rough work of clearing and digging the ground, apart from their lack of the necessary skill to plant a single tree. Such has been almost the universal experience of those who have attempted to utilise labour of this kind in even the preliminary stages of afforestation.

In formulating any scheme the aim should be to replace temporary palliatives by systematic treatment, and carefully to differentiate between the varying classes of the unemployed. They may be roughly placed in three categories:—(1) Those who from physical infirmity or age are unable to work. For these the contemplated insurance against sickness and invalidity combined with old-age pensions will ultimately provide, but it must be remembered that a considerable proportion of men and women in this category have already fallen out of the ranks in middle life or earlier, and for them the time of insurance is past. What is primarily required is a strong Central Public Assistance "Division," as recommended by the Poor Law Commissioners, representative of and partially directing the Public Assistance authorities in counties and county boroughs. With them all forms of voluntary aid should be connected. The Charity Commissioners would need some reorganisation, and should be attached to the Local Government Board. Under schemes passed by the Commission there would be Voluntary Aid Councils in the counties and county boroughs, and Voluntary Aid Committees. This utilisation of the aid and experience of those who have hitherto been administering charities, together with an Elberfeld system modified to meet English conditions, is indispensable to prevent overlapping and to ensure that effective provision shall be made. (2) Those who, for economic or industrial reasons, cannot find employment; and (3) those who are unemployable owing to defects in character. To-night we are concerned with the unemployed rather than with the unemployable, but it is necessary

briefly to refer to the latter in the hope of removing the false impression which still exists that those who press for the introduction of the Dutch system for the benefit of the former are advocating something which has proved unsuccessful in other countries. In reality the Colonies in Holland differ *toto cœlo* from those established elsewhere. Since the world began, every State has been vexed by the presence of the unemployable, and the social economist is justified in saying that in their case the problem is mainly a moral one, but the question cannot be thus summarily dismissed. *Nemo repente fuit turpissimus.* In many cases the man is the victim of circumstances, and of the environment in which he is compelled to live. He is, especially in childhood and adolescence, like an animal at pasture; from the things which he sees and hears about him he assimilates little by little the good or evil which they embody, and which becomes part and parcel of himself. To build up the self-respecting citizen it is imperative for the State to improve the man's surroundings, and to remove the obstacles which render the good life practically unattainable amidst the squalor of the slums. The magnitude of the evils by which we are confronted is due to the past iniquitous attitude of *laissez-faire*, but, whether the failures are attributable to our neglect or not, we are called upon to deal with them for the welfare of society, and the methods for doing so are as old as Ancient Greece. Plato realised that expulsion is the only alternative to reversion to an ordered life. He recognised that a man may become so entirely disordered and wrecked as to be incapable of revival, and should be sent to what was euphemistically termed a "Colony." To such a Colony the majority of those in Belgium, Germany and Switzerland closely correspond.

Belgium.—In Belgium there are two types of Colony, *Dépôts de Mendicité* and *Maisons de Refuge.* The latter are intended for the aged and infirm, or for men temporarily unemployed, and resemble the English workhouse. The former are for professional beggars or vagrants, and for persons convicted of various crimes. The principal Dépôt is at Merxplas, where the inmates number about 5,000. Three years is the maximum period of detention, but the average time is only about sixteen months. Two great defects in the organisation are the lack of any classification of the inmates, and the absence of any religious influence. In the opinion of the Director little reformation is to be hoped for from the treatment there. "Once a colonist, always a colonist," seems to be the ultimate verdict. The number of entries tends to increase yearly; recently the population amounted to 5,110, of whom 5·9 per cent. only were there for the first time, while 72 per cent. had returned at least four times. It is true that the compulsory Labour Colonies have done much towards clearing the country of beggars and tramps, but as regards any systematic effort to solve the "unemployed" problem, Belgium can teach us little. In his valuable work on "Land and Labour: Lessons from Belgium," Mr. Rowntree points out that probably the most important factor in lessening the suffering due to unemployment in that country is the economic stability given to a large proportion of working-men by the fact that they are enabled to live in the country through the extraordinary cheapness of workmen's railway tickets. They generally have a plot of land, and, if they are seasonal workers, rely upon the period of unemployment for digging and manuring the ground. For such men unemployment is not synonymous with abject poverty, as is often the case in England. Relief works for the unemployed are only provided on a very small scale, but an interesting experiment has been made by a few of the Trade Unions in establishing workshops—*Ateliers de Chômage*—in which their unemployed members may work at their own trades. One of the largest of these is that of the cigar-makers at Ghent, which was started some thirty years ago.

Germany.—In Germany there are thirty-four Labour Colonies, the first of which was established in Westphalia in 1882, under the management of a charitable association—the Labour Colony Central Board—providing accommodation for 4,000 persons. Admission is voluntary, there is no compulsion to remain, although apparently some attempt is made to induce the men to stay for not less than two months. Under these conditions it is idle to expect any reformatory influence to be exercised. The inmates are largely recruited from the criminal classes, who by their presence drive away the honest workman, whose chance of subsequent employment might be seriously diminished from his having had recourse to such an institution. The Colony at Schäferhof, near Hamburg, is somewhat differently constituted. Its Director states that a genuine effort is made to persuade the inmates to stay there long enough to make it possible to effect a substantial change in their moral and industrial character, and that "reclamation is effected in the case of about

10 per cent. of the inmates." For habitual vagrants there are twenty-four *Arbeitshäuser*, which, to some extent, resemble the original Houses of Correction here and the forced Labour Farms of Switzerland. Under Sections 361 and 362 of the Imperial Code, vagrants, beggars, and those who cause their children to beg; those who through their own discreditable conduct have to apply for relief; and anyone who, after losing his lodging, fails to procure another within a certain time, may be committed for detention in an *Arbeitshaus* after serving a term of imprisonment. The average period of detention is about a year. The *Arbeitshäuser*, which can accommodate about 15,000 people, are controlled by the authorities of the Province, being in fact a kind of prison under strict military discipline. During recent years there has been a marked decrease in the number of the inmates, and vagrancy is certainly diminishing. Professor Mavor, in the Board of Trade Report of 1893, states that all the evidence with regard to Colonies of the type of Merxplas is against the supposition that such institutions are reformatory; "they form merely a receptacle for those who, if they were free, would prey upon society and render means for relieving the deserving poor wholly futile." With the *Herbergen*, a sort of model lodging-house for destitute wayfarers, and the *Verplegungs-Stationen* (relief stations) this paper is not concerned.

Switzerland.—Switzerland has three voluntary Labour Colonies, managed by philanthropic societies, where the men must consent to remain for one or two months. In nearly every Canton there is a compulsory Colony or forced Labour Farm, to which beggars may be committed for detention for a period of from three months to two years. As a rule these Colonies are small; at Witzwyl, the largest, the number of inmates does not exceed 200. The farms are worked economically, and there are workshops at which various industries are carried on, but, as at Merxplas, no trades appear to be taught. At Witzwyl the staff number forty-five, or one to every five inmates. Mr. Preston Thomas reported to the Departmental Committee on Vagrancy, 1906, that the men there did really work hard, and that the results of their work were visible on every hand. As he truly observed, "When a man sees the products of his labour, which have grown up before his eyes, he is induced to exert himself, and is stimulated in a fashion which contrasts with the leaden monotony of such occupations as stone-breaking and corn-grinding." On discharge, a man is provided for either by (*a*) employment as a paid labourer at the Colony; (*b*) the action of a discharged prisoners' aid society; or (*c*) admission into a voluntary farm. The system pursued in Switzerland seems to have met with more success than that in either Belgium or Germany, but the results in each case are such as to justify Mr. Loch in saying that one can expect no large or general transformation of character from the adoption of a similar system.

Holland.—The Dutch Free Labour Colonies at Frederiksoord, Wilhelmsoord, Wilhelminasoord and Boschoord, which are quite distinct from the Penal Colonies now controlled by the Government, suggest, *mutatis mutandis*, the best method of solving the problem of unemployment in so far as it relates to those unemployed from no moral or physical defect. They are under the direction of the Society of Benevolence (*de Maatschappij van Weldadigheid*), which was founded by General van der Bosch in 1818, owing to the distress occasioned by the famine of that year, and which took for its motto, "Help the Poor and improve the Land." The entire management is in the hands of a single administration, with headquarters at Frederiksoord. Local committees have been formed throughout Holland, whose first duty is to enlist members for the society, the minimum subscription being 3*s.* 6*d.* per annum. After deducting expenses incurred by a local committee, the balance is transmitted to the Director at Frederiksoord and credited to that committee. As soon as this amounts to £141 3*s.* 4*d.*, the general committee, which meets once a year, may entitle the committee to send one family to the Colony after consideration of its fitness. The aim is to assist respectable persons who cannot earn a livelihood in the towns. Children below the age of twelve, who are being maintained in various municipal institutions, are admitted and boarded out with suitable families. A special superintendent is appointed for their protection. The average number of boarded-out children at Frederiksoord is about 250, of whom about twenty-five are annually placed in situations outside the Colony. In the opinion of Heer Boissevain, the Director, the work of the society with regard to both the boarded-out children and those of the colonists has proved a great success.

Organisation of the Colonies.—The total estate of the society comprises some 10,000 acres, formerly heath and sand, which has now been brought into a condition of high fertility, and the

average number of colonists, with their families, is 3,000. On arrival at Frederiksoord each family is provided with a separate cottage and garden. Their immediate wants are supplied, not as a gift, but by way of advances to be repaid by instalments. A sheep is given, which can be pastured on the society's land for a small weekly sum. A certain sense of ownership and responsibility is thus imparted from the very beginning. Those who are able to work are at once engaged in various agricultural and industrial occupations, according to their capacity. In addition to agriculture, the following industries are carried on:—Mat-making, smithy work, tailoring, carpentry, bricklaying, basket and furniture making, and forestry. The equipment for each of these is admirable. Wages are paid upon the scale common to the neighbourhood. From these are deducted the instalments on the debt incurred on arrival, house-rent not exceeding 4*d*. a week, one cent., or less than a farthing, as infirmary fee for each person, about a penny for the clothing fund, and 10 per cent. of the gross earnings as a reserve for the family emergency fund. The endeavour throughout is to restore the individual, develop his industrial potentialities, and encourage habits of thrift. It is realised that this cannot be effected in a few weeks or months, and two years of training and probation are insisted upon. If at the expiration of that time a man shows no inclination or capacity to work, he must leave. If, on the other hand, he shows himself to be reliable and industrious, he is eligible for promotion to the position of a "free farmer," and, if there be a vacancy, is put on a small farm of about 6½ acres, the rent of which varies with the condition and quality of the soil, ranging from £2 18*s*. to £6 5*s*. a year. He then receives seed and stock on loan—generally a cow valued at £10, and seed to the value of £4 3*s*. 4*d*. This capital sum has to be repaid with interest at the rate of 12*s*. per annum, and about £2 3*s*. 4*d*. worth of manure must be put on the land each year. The "free farmers" have now a co-operative dairy and a co-operative society for supplying themselves with fodder.

Education.—In some respects the most valuable and permanent of the society's efforts is the extreme care to ensure that the children of the colonists shall be thoroughly educated. In fact, the education provided within the area of the Colonies precisely illustrates the education which ought to be accessible to every child in every country. At Frederiksoord, for example, there are five public primary schools. Boys, on leaving them, must attend a continuation class for two years, and girls a domestic science class until their sixteenth year. The lads are trained for various trades, the railway, post or telegraph services, the army (there is a flourishing lads' brigade), the navy, or as farmers or gardeners. Intermediate schools of horticulture, agriculture and forestry have been established, each of which has an annual subsidy from the State. The horticultural school, which is attended by lads of fifteen for three years, and receives a subsidy of £400 per annum, has an extensive and well-kept garden of 12 acres, cultivated entirely by the pupils. It is not confined to the sons of colonists, and it is gratifying to know that no ill-feeling exists between the children of independent parents and those of the inmates. Theoretical instruction is given at the agricultural school during two winters, and practical work is done on one of the society's farms in the summer. The school of forestry, with a course of two years, has a large nursery and some 60 acres for clearing.

Criticisms.—The proper function of a Labour Colony is to act as a bridge for the unemployed, and to pass on a succession of trained and rehabilitated men. No human institution, however, is perfect, and this function the Dutch Colonies have, as a rule, failed to perform. Few of the men display the slightest inclination to exchange their protected position in the Colonies for one outside. But to this criticism the Dutch are entitled to reply that they have for nearly a century been providing permanent homes and employment for otherwise destitute men, and have to that extent relieved the congestion of the towns, while at the same time they have rescued the children of the colonists from the degradation of the streets, educating them and training them into useful citizens. To have exercised this civilising and redemptive influence over so long a period is no mean achievement. It must be recognised, too, that poor families living in towns frequently become accustomed to receive relief from their childhood, and parents encourage their children to beg. They are exploited in every way, and, as a result, numbers of them are morally and physically ruined. The same municipalities which have assisted the parents will afterwards have to support the children. From every point of view it is desirable to remove such families from the towns and put them to some useful employment, ensuring meanwhile the future of the children.

In the extremely meagre account of the

Colonies in the Report of the Poor Law Commissioners, a point is made by the Committee which visited them of the fact that no townsman could be found amongst the "free farmers." Now, it is open to very serious doubt whether men, debilitated and demoralised by town life, can ever become successful agriculturists. That, however, is not the type of man for whom the proposed Colonies are designed.

It is further objected on economic grounds that the Colonies are not self-supporting, but the deficiency that has to be annually met from outside sources is trivial compared with what the municipalities would have to pay for the relief of such families, or for their maintenance in workhouses, asylums or prisons.

Advantages of the System.—Briefly, the merits of the Dutch system may be thus summarised:—

1. That a man is settled *with his family* on the land, and that a cottage is provided for him, for which rent is paid.

2. That the men are employed at once on the farms connected with the Colonies or in other occupations.

3. That temporary advances on loan are made for whatever may be necessary to furnish the home and to satisfy the immediate wants of the family, and that these advances are repaid by deductions from the weekly wages which are paid for the labour of the family according to the scale prevailing in the vicinity of the Colonies.

4. That after two years a labourer of industrious habits may be promoted to the position of a small farmer, the Colony rendering him every assistance in the development of his land.

5. That all children of the colonists have excellent primary education, are compelled to attend continuation schools, and receive technical instruction in agriculture, horticulture, forestry, or whatever industry they may prefer.

6. That, although no special means are taken to bring the colonists under moral or religious influence, a religious spirit, entirely free from sectarian prejudice, pervades the whole scheme. Frederiksoord, for instance, possesses one Roman Catholic and two Protestant churches.

Application to England.—In advocating the introduction into England of something analogous to the Dutch system, it must be remembered that the Vagrancy Committee of 1906, and both the Majority and Minority Reports of the Poor Law Commissioners recommended the establishment of Labour Colonies. That some practicable scheme for restoring the able-bodied unemployed of good character to remunerative work is imperatively needed nobody denies. Even in years when trade is flourishing the minimum of unemployment is tending to rise. This was admitted by Sir H. Llewellyn Smith in his speech foreshadowing a scheme of national insurance. When an effective scheme of insurance against unemployment comes into operation, the evils may be mitigated; no benefit, however, can accrue therefrom to those who are to-day in want of work, and we cannot afford to wait.

Undoubtedly the Labour Exchanges are bringing the unemployed into touch with places where there is a demand for them, but the demand can never under existing circumstances equal the supply. No surprise need be felt that Mr. John Burns should still hesitate to commit himself to any proposals for establishing a Colony of the type suggested. The experience of Labour Colonies in this country has not been such as to inspire confidence, but the causes of their failure, comparative or otherwise, are not far to seek, although it would be invidious to enlarge upon them here. The improvement of Dutch methods and their adaptation to English requirements ought to present little difficulty, and it has been urged that the Government should without delay establish at least one Colony upon the following lines:—

1. The unemployed for whom the Colony is intended, must be carefully selected, preferably country-bred or accustomed to the use of a spade, and must contract to remain there for two years. If during that period they prove unfit for the work, or in any way unsatisfactory, they should be removed to a Colony of a more or less penal character, and in no case be abandoned to their own resources.

2. The men to be settled on the Colony ought to be accompanied by their families and housed in cottages which should not cost more than about £140 each.

3. Arrangements as to loans of money and stock might follow the Dutch plan, while wages would be paid at the current rate of the locality.

4. Provision for the efficient education of the children, as in Holland, is essential.

5. During the two years' probation the men should receive instruction upon soils; manuring; the management of stock; the choice and selection of seeds; vegetable and fruit culture; pig, poultry and bee keeping; the grading, packing and marketing of produce; and especially in the principles and practice of co-operative production and distribution. In addition to the land subdivided amongst the

colonists, there should be experimental or demonstration plots, together with a farm and a garden to illustrate the best and most scientific methods of cultivation.

6. At the expiration of the two years the men ought to be qualified to join an independent and co-operative association of small-holders, as contemplated by the Small Holdings Act and encouraged by the Board of Agriculture. Such associations might be formed in the neighbourhood of each Colony, but to facilitate their organisation and development Agricultural Credit Banks, which have assisted the Irish farmer so materially, should be promoted on the model of the Raffeisen Banks to be found in many Continental countries. In this latter respect the Board of Agriculture might safely be relied upon for sympathy and support.

There could hardly be a more beneficial object to which a portion of the Development Grant might be applied than in the establishment of such a Colony. Land suitable to the purpose abounds, and, if the initial experiment succeeded, each county council might establish one within its area for a hundred inmates or whatever number local needs required, and organise it in accordance with local circumstances. Improve the land by the man and the man by the land. That is the fundamental principle. No scheme yet before the public seems so well calculated to diminish the volume of unemployment, to restore the balance between rural and urban population, and to secure a priceless benefit to the nation by repopulating the rural districts with a race of contented, healthy and prosperous cultivators of the soil.

DISCUSSION.

The Chairman, in opening the discussion, cordially welcomed His Excellency the Netherlands Minister, who was present. With regard to the right to work, he said he should prefer himself to use the word duty. Mr. Medd had said that there were probably more unemployed than work for them to do, but in Lancashire at this moment he believed there was more demand for labour than labourers to meet the demand. In Scotland there was occasionally difficulty in finding unskilled labour to repair roads. In Switzerland a referendum was taken with regard to the principle of the right to work, with the result that on June 3rd, 1894, 75,880 voted for the principle and 308,289 against, and, what was very rare, the whole of the Cantons opposed the principle. The argument seemed to have been the difficulty or impossibility of putting it into practice under a non-socialistic organisation of society; and on the other hand that if Socialism prevailed there would be no longer any need for the right to work. The great Socialist Liebknecht in Germany only praised it as a demonstration, and Bebel spoke of it very slightingly. Mr. Medd had rightly laid stress on the importance of the classification of the unemployed, and of putting on to the land only those who were fit to perform agricultural work. The cry of "Back to the land" was delusive. He had been told by a farmer in Scotland that if one of his men spent a year in a town, on his return to the farm he was unfit for agricultural work. It was necessary to be careful not to draft into the country those who lacked the necessary qualifications for rural life. In France, military service had made the men drawn from the land in many cases very unwilling to go back. The endeavour should be to keep the present population already on the land, and to take care that their children were so educated as to look on country life as offering them a congenial sphere of activity. The main feature of the Dutch system was that the people sent to the Colonies were sent there not by the Government but by voluntary effort; the committees were all self-supporting and the governors of the Society of Benevolence men of the highest standing. Mr. Medd had urged that the British Government should without delay establish a Colony on certain lines, but he would prefer strictly to adhere to the Dutch lines, the Colony being managed by a private association, which of course should be in close relation with such Government agencies as existed for the unemployed. He agreed that it was important to correlate voluntary agencies with Government agencies, and he believed that in the Bill which had been introduced in Holland for the reform of the Poor Law one of the principles was a closer connection between the State and the voluntary associations. He thought one of the most beneficial societies in England was Dr. Barnardo's Homes. They had been of the greatest benefit both to the children sent to Canada and to the Canadian farmers, who asked that the boys should be sent to them young, before they had had any experience of city life, so that they might be inured to the rather rough life in the west of Canada. Mr. Medd suggested that men, after having spent two years in the Colonies, should become small holders. If small holdings were to succeed, it was very desirable to locate them in numbers and not scatter the holdings all over the country, so that there might be co-operation and a system of credit banks. He agreed with Mr. Medd that those who showed themselves during the probation period to be unfit for agricultural labour should be at once weeded out, because obviously at first there would be more people applying than could be dealt with by the Colony. They could therefore admit in the first instance the most fit. It seemed to him that the all-important point of the Dutch plan was that a man was immediately put in a position of some responsibility and made to feel that he was trusted; he was put in a position where by industry and self-help he gained

a feeling of self-respect, the loss of which was at the root of so much of the misery in this country. He invited those who had not seen the Dutch Colonies to pay them a visit. The horticultural school was an important feature. The status of the colonists was shown by the fact that those who came for an independent training mixed with the sons of the colonists without any feeling of class restriction. He trusted that the Dutch experiment would be carried out here exactly on the Dutch lines by means of voluntary effort, with a grant from the Development Fund and inspection by the Board of Agriculture. Mr. Medd's paper was a valuable contribution to our knowledge of a very difficult problem.

Mr. T. EDMUND HARVEY, M.P., expressed his gratitude to the author for the suggestions contained in the paper, though he could not quite agree with the criticism of the Central Unemployed Body. As a former member of that body, he thought he might say that, although the members of it were dissatisfied with the work, yet a great measure of the failure was due to the imperfections of the Act, which was only a temporary one set up as an experiment. It had done sufficient, however, to show some of the lines along which the problem had to be attacked. It should be remembered that the Hollesley Bay Colony was at first intended as a means of placing upon the land in small holdings, as co-operative farmers if possible, the most successful of the colonists, but, owing to the restrictions of the Act and the views of the Local Government Board, that was impossible, and therefore the experiment was bound, to some extent, to be a failure. There were no means of dealing with the men who were unwilling to work other than sending them away, so that the penalty fell upon the family. If there was a system of detention Colonies, by which a man could be kept until he had received the necessary moral and physical discipline to fit him for a useful place in life, then he thought the Colony would have greater possibilities. The Act was really a step forward, marking an increased sense of responsibility in the nation for the wastage of our industrial system. He differed somewhat from the Chairman in connection with the relation to the State of any future experiment, hoping it was possible to combine the Dutch experience with something better. The Majority and Minority Reports were in substantial agreement in recommending a system of Colonies with detention Colonies in the background, and he thought no great mistake could be made in adopting their recommendation. He hoped to see a system established in the near future giving free play to voluntary enterprise and having the necessary help of the State, with a detention Colony for cases that were beyond the help of the voluntary Colony. Then the help of the great religious agencies, the Church Army, the Salvation Army, the Christian Social Union, and other organisations, could be called in. It had to be recognised that the present Poor Law system had failed in dealing with the problem of the able-bodied, although the intention of the Poor Law was admirable. The Government should be called upon not simply to be content with renewing from year to year an Act which was a necessary and useful experiment in its time, but to go forward with legislation which was absolutely necessary, and which was demanded alike by schools of thought so different as those represented in the Majority and Minority Reports.

Mr. T. CUTTER said he had been struck by the absence of any remark as to the wages paid in the Labour Colonies. He thought it unfair to criticise the Central Unemployed Body without considering the matter from the English standpoint. The Hollesley Bay Committee had to deal with men accustomed to urban work sent to the Colony to learn agriculture, and he did not think a more hopeless project could exist. On an independent visit to Hollesley Bay he found an Essex ploughman, followed by seven or eight colonists, ploughing a field. They said they were learning to plough. He asked them on what conditions they were there, and one man, who came from Birmingham, said his family were being paid 9*s.* a week and he himself was receiving about 10*s.* a week, which brought the total wages up to 19*s.* His hours were less than those of the ploughman and he had the Saturday afternoon off, which the ploughman did not. The ploughman said he received 14*s.* a week, out of which he paid his own house rent and maintained his wife and family. Therefore men totally unsuited for agricultural work were receiving higher wages than the skilled agricultural labourer on the spot. He asked one of the colonists whether, if he learnt to do the work, he would be prepared to stay in the district at 14*s.* a week, and he said he would not. Men accustomed to big cities, with its cheap music-hall pleasures, were not very willing to go into rural districts at all. His experience was that the Unemployed Committee were dealing with a hopeless problem in attempting to make an unemployed man from the Metropolis into a farm labourer.

The Rev. J. H. ANDERSON (Chairman of the London (Central) Unemployed Body) said he had had the bitter experience of finding that it was a very hard thing to preach the duty to work when there was not enough work to go round. It was no use telling people they had a right to work in an industrial system which did not give men the opportunity of performing the elementary duty of maintaining themselves and their families. As Hollesley Bay had been mentioned, he should like to say—and he believed the Body he represented agreed—that the defect of Hollesley Bay was that it had never been allowed the proper outlet for men which training there might have been expected to fit them for. After a period, all too short, of sixteen weeks, men went back again to the place from which they came. That, however, was not the fault of the Unemployed Body or of the Local Government Board. Whenever a selected body of men had been put forward to the Local Government

Board for permission to continue their training, the Local Government Board had never refused, and there were men who had been there for years. After a year a man was located in a cottage adjacent to the estate, and became an ordinary labourer on the estate. The trend of opinion on the Central Body was in accordance with the principle advocated by the author. The Board of Agriculture had been already approached with the view to enabling some of the two-year trained men to obtain small holdings, and the London County Council had been asked to put into action the powers they had under the Allotments and Small Holdings Act; but he regretted to say that up to the present time very scant encouragement had been received for those laudable enterprises advocated by the author and already put into practice by the Central Unemployed Body. With regard to financial conditions, when a country labourer was asked what he received, he would mention his weekly wages of 14*s*., but would say nothing of his harvest money, or the amenities of his cottage, or of the pigs and the hens, and all the rest of it. Perhaps it could not be said that his wages would amount to that actually paid on the Hollesley Bay estate, but the wages paid to the colonists had to be paid, not on the basis of what was paid in the immediate neighbourhood, but on the basis of the necessities of family life in the Metropolis. The men left behind in the Metropolis their wives and families, who were paying rents very different from the rents in Suffolk. The total cost of a family only amounted on the average to £1 6*s*. 6*d*. per week, and that compared very favourably with the amount paid by analogous bodies. It had been stated that the amount paid was 19*s*. per week, but the highest sum in the scale at Hollesley Bay was 17*s*. 6*d*. It had not been possible to place trained men on small holdings, but they had been placed with farmers who were glad to have men who had had some training in the Colony. During the last year thirty-five such men had been placed, with regard to thirty of whom very satisfactory reports had been received. Of the other five, two were doing well in work other than agricultural, and only three had proved failures.

Mr. D. F. Schloss said it had been his duty to visit all the Colonies mentioned by the author, some of them more than once, either for the Board of Trade or for the Poor Law Commission. He understood the author's argument to be that all the Labour Colonies that had been tried had proved a failure. He agreed with all the facts the author had mentioned in connection with the imperfections or failure of the Colonies, but whether they formed a sufficient basis for the proposal to start a series of Labour Colonies in this country he would rather not venture to say. But as something had been said about the remarkable results of the Dutch Labour Colonies, and as the author had not had time to go into those results except to say that they were not satisfactory, he should like to give a few exact figures. Those figures would not prove the success of the Dutch Labour Colonies, because those Colonies were not successful in solving the problem which was under discussion that evening. What the Dutch Labour Colonies did for the children was beyond all praise and deserving of imitation, but they did not succeed with respect to adults, and he thought it would be very wonderful if they did. The measure of their success was the number of men whom they raised to the position of independence, the men who from the position of labourers in the Colony were advanced to that of free farmers. In 1889 five new families came, and five were promoted to free farmers, and the figures were much the same for the next few years. In 1893, three new families came, and one man was elevated to a free farmer. In 1894 none came, and one was elevated, while from the year 1895 to 1902 the figures for those who came were respectively two, one, one, four, two, none, one, and none, and during those years not one family was elevated to the position of free farmer. He had no figures with regard to the years 1903–4, but in 1905–7 there were fourteen or fifteen new families and between ten and twelve free farmers. When he was there in 1908 there were 100 colonists and 250 free farmers. If the families were promoted after a period of two or three years, instead of being 100 labourers there, there would have been only about a dozen, and therefore the aim of the Colony did not seem to be fulfilled. There were three things that appeared to account for that want of success. In the first place, he was told by the Director that very little discrimination was exercised in admitting new families, people being chosen who were destitute and had large families. When the Poor Law Commissioners were going round, and could not find a single person from a town who had been promoted to be a free farmer, it was explained that they were persons debilitated by town life. Another remarkable thing was the total absence of anything like systematic agricultural training, and there was also an absence of systematic religious influence. The Poor Law Commissioners asked the Director whether there was any missioner or any attempt to influence the people from a moral or religious point of view, and he said there was not. There were churches with a capital of eighty millions, and the total sum for religious services appearing in their budget was £38 a year. He thought it was futile to discuss the purely economic side of the question from the point of view of the balance-sheet, which he had never been able to understand. There was nothing charged for rent, and only a very small sum charged for interest. One of the best tests of the success of such a large Colony of 10,000 acres was how far they could utilise the means in their possession, and at the present moment they had 100 farms which they let because they could not fill them. The Dutch Labour Colonies therefore were not entirely successful, but whether that was a reason for adopting the Dutch system in this country he was not prepared to say. He did not thoroughly understand the

exact plan proposed by the author or the kind of men who were to go to the Colony. They were to be taught an enormous number of very difficult things in two years, and, if they did not succeed in learning them, it appeared they were to be removed to a Colony of a more or less penal character. It would seem that a man would be brought before a magistrate on the charge that he had failed to learn agriculture in two years, and the sentence was to be indefinite detention!

Mr. J. C. Medd, in reply, remarked that what Mr. Schloss said was very interesting, but he was afraid Mr. Schloss did not quite realise that the suggested Colony in England would be entirely free from the defects which had caused the comparative failure of the Colonies in Holland. The principle upon which the Colony would be organised in England was that no man would be allowed to remain in it beyond a period of two years. The criticism passed in the paper upon the Dutch Colonies was that they allowed the men to remain practically for ever upon the estate, and that, he thought, was the chief cause why they had failed. What he wanted to impress upon Mr. John Burns was not to reproduce in England anything in the nature of an exact copy of a Dutch Colony, but to adopt the principles on which the Colonies in Holland originated: the removal of the whole family from the contaminating influence of the town, and the essential importance of thorough education for the children. Even if the Dutch Colonies had been prevented by accident from rehabilitating and sending forth into the world again the head of the family, they had at any rate succeeded in educating and forming a group of most useful citizens for nearly a century. It was easy to criticise any institution, but in the present case it was not the institution that was to be imitated but the principles which governed it; and until someone presented an outline of a Colony with more enlightened principles than those which actuated the founders of the Dutch Colonies, he should venture to believe that those were the soundest principles. If he had appeared to criticise the action of the Central Unemployed Body it was not his intention to do so, because he knew perfectly well the limitations under which they had been compelled to act. He merely referred to their action because he believed that the failure, comparative or otherwise, of the Colonies in England had been due to ignoring the two essential facts, namely, taking the whole family and insisting on the man remaining for more than two or three years. With regard to the wages question, what Mr. Anderson had said was quite correct; the weekly wage of an agricultural labourer was very little indication of his annual earnings. It was quite erroneous to compare the wages which a man fully employed in London could earn with the wages of an agricultural labourer. The case under consideration was that of the unemployed, the man who started from zero, who, if he had a chance of earning 19*s.* a week was obviously in a much better position than he would be in London earning nothing. He fully acknowledged the force of the criticism with regard to the free farmers, and provided for it in the suggested organisation. The whole paper was based on the assumption that there were men capable of doing good work, but who, from circumstances beyond their control, were unable to find that work. If Mr. Schloss believed there were no such men in England he could only say that he differed from him.

In conclusion he thanked Lord Reay for his kindness in taking the chair that evening, and joined with him in thanking his Excellency, the Minister for the Netherlands, for being present to listen to the paper and the discussion.

On the motion of the Chairman a vote of thanks was accorded to the author for his paper, and the meeting terminated.

SAGO-MAKING IN CERAM.

Ceram—one of the Moluccas—is probably the metropolis of native sago-manufacture in that part of the world. In the early part of 1909 there were two of us on a zoological expedition in the

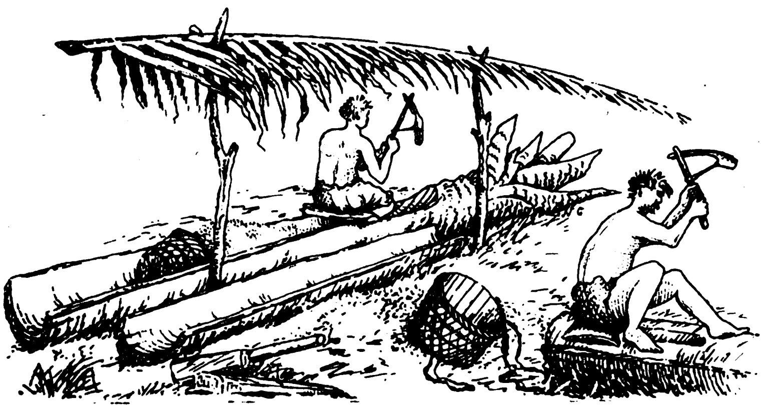
Sago Palms, Old and Young, in Swamp.

Dutch East Indies, and our work kept us continually amongst the sago-swamps during the four months we spent at Piroe, a small village in western Ceram, and the nearest port to Amboyna or Ambon, as it is called by the Dutch and Malays. The only white men in Piroe (there are probably but half-a-dozen in the whole island) were the Resident, two Dutch soldiers, and a missionary. A small native war—difficult and desultory forest-fighting—was

in progress against certain Ceramese tribes; and we lived in a compound occupied by about twenty Amboynese soldiers, the forest closing us in on every side but towards the sea. The whole of this large island is practically covered with forest, and the greater area is very mountainous; but there is much low-lying coastal land, and there the sago-palm (*Metroxylon Sagu* of botanists, a species which only occurs in the East Indian Archipelago) grows luxuriantly. It is turned to almost as many uses as the bamboo, for besides furnishing sago, its leaf-fronds provide "attap" or thatch; the whole mid-ribs of the leaves, termed "gaba-gaba," make rafters and posts for houses, and when split are used for floors and walls; split into smaller strips they make excellent cord.

Many people seem to think that coco-nuts and other fruits growing in these wild countries may be plucked by anybody who wants them; but all such trees, even in the depths of the forest, are private property, and the sago-palm is no exception. Every palm is owned either privately or by villages, or the treacle. On this we practically lived whilst at Piroe.

Natives come to Ceram, which is very thinly populated, from Ambon and many other islands far and near; procure a Government licence to cut so many trees, and live and work in a sago-swamp till they have converted the trees into sago, sailing for home with the finished product. The trunk of the palm often attains forty-five feet in length to where the leaf-fronds spring, and a diameter of two feet; but thirty feet to the crown is a fair average, and even then the trunk will usually measure two feet in diameter. Such trees at Piroe cost, standing, two to three guilders each (about four shillings), and one man can fell, extract the pith, build the washing apparatus, and prepare the sago in about fifteen days, if he works hard; but the Malay is not fond of hard work or indeed any work, and in these islands he can live almost without labour. From one sago-palm he can obtain a supply of food which, varied a little with fish and vegetables, will last him many months. The natives distin-



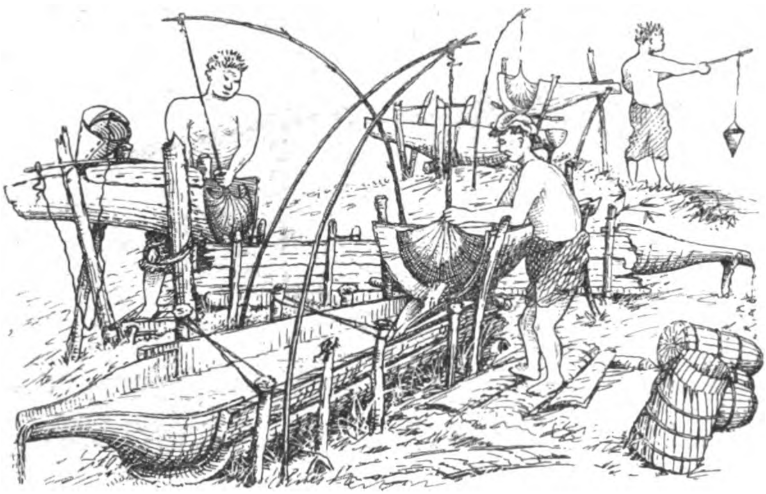
Cutting out the Pith.

Dutch Government; but the trees and prepared sago are sold so cheaply that probably no death from starvation is ever heard of in the Dutch East Indies, for the sago from Ceram is sent all over the islands.

Now the sago of the shops in civilised countries is familiar to everyone, but it is doubtful if many people would recognise the native article as sago, or sagu, to call it by its native name—sargoo as the Malay pronounces it. Neither appearance nor taste have much in common with the sago one buys in England. The brick or cake sago we did not appreciate, though the Malay children gnaw it with great satisfaction, and it is so hard and tough that it lasts for hours and requires splendid teeth—and probably a first-class digestion—to tackle it; a cake looks and feels very much like gray or pinky-white sawdust, strongly compressed. When boiled, however, it is of a darkish-brown colour and gelatinous, and very nice when eaten with native sugar syrup, made from another species of palm and resembling thin, burnt guish four varieties of palm, viz.: *Sagu duri* and *S. makanaru*, which are both thorny, the young trees being armed on trunk and leaf-sheaths with immense, strong slender spines, sharp as needles; and *S. tuni* and *S. mollea*, which are thornless. The amount of sago produced from these palms varies from about ten packages of finished sago from *S. makanaru* to eighteen or twenty from the other trees, each package weighing about twenty-five catties (say eighty pounds). The life of a palm is said to be about ten years before it is ready for felling; this is done as soon as the flower-spike appears, and the tree is always cut down before it is in full flower, otherwise much of the pith is spoilt.

The palm is first of all chopped down close to the ground with parangs, or native swords, and the leaf-stalks lopped off; a transverse cut is made half-way through the trunk about its mid-length, and wooden wedges driven with a heavy wooden mallet in a longitudinal line from both sides, thus splitting off the upper part, which is rolled over

alongside. Each half-trunk now has the pith exposed; strong and fibrous and intimately mixed with the starchy substance, and of a rusty or reddish-white; this is gradually chipped away with a bamboo adze, the operator meanwhile sitting astride the trunk at one end on a piece of leaf-sheath, and slowly cutting his way to the other end, whilst the broken-down pith—like coarse pinky-white sawdust—accumulates behind him in the hollowed-out trunk; for the rind is tough and hard, about an inch thick, and forms an excellent trough. The pith is then thrown into palm-leaf baskets or dumped on the ground; the hollowed half-trunk is fixed up with a few pieces of leaf-stem underneath and stakes along each side, the latter usually lashed together with rattan across the trough, the sides of which are often heightened by the addition of a split piece of trunk each side. Two large leaf-sheaths are now cut to form the basket of pith into the strainer-trough along with a few buckets of water from the nearest pool or stream—one has not far to wander for water in a sago-swamp, and the native is not particular as to its purity. Then, grasping the cord of the strainer and bending down the spring with his left hand, he mixes up the mass in the trough with his right, and presses a handful against the strainer. The white, starchy liquid flows out into the settling-trough, fresh pith is added and the refuse thrown out from time to time; the starch in the milky fluid of the settling-trough soon settles to the bottom, and the surplus water slowly flows away from the spout at the end; here it is often caught in a second settling-trough at a little lower level, so as to recover more of the starch. As soon as the bed of starch—like thick plaster of Paris—nearly fills up the trough, it is scooped out in masses with the hands, rolled on the left fore-arm



WASHING THE PITH.

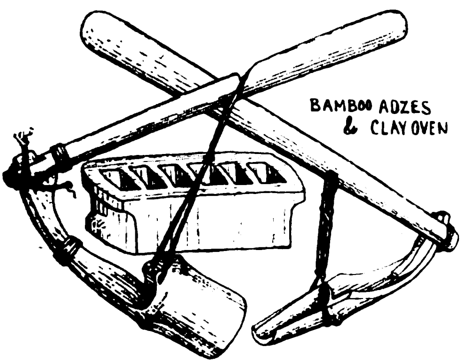
strainer-trough at one end of the main or settling-trough, and the overflow spout at the other. The strainer-trough is supported by stakes at a convenient height to work at; the small end is blocked with a piece of leaf-sheath, and a strainer is fixed at the large end. This strainer is made of segments of the reticulated fibre swathing the bases of the leaf-sheaths of the coco-nut (something like very coarse cloth or sieve-net), neatly sewn together with twine made from thin strips of sago-leaf; the edge of the strainer is turned up or flanged and sewn to the interior of the trough, just inside the large end. The upper end of the strainer is attached to a piece of leaf-cord, and kept stretched by means of a couple of springs made of bamboo or split leaf-stem. A small piece of leaf-sheath is usually placed beneath the strainer-trough to serve as a spout to the settling-trough. The whole apparatus is called the *gutti* or *gouti*, pronounced *gooty* by the natives.

The *gutti* being erected, the operator dumps a into rough sausages, and dropped into sago-leaf jars, in which a little pith refuse has been placed; a little more refuse is plastered on the top, and more leaves are then sewn on and bound over the whole package with rings of leaf-strip. The remainder of the tree is then attacked and converted into sago; the reason why the whole tree is not split at once being that if the pith is exposed too long to the weather, it soon deteriorates—besides, the Malay likes to do things leisurely.

The ground, or rather morass, in which the sago-makers work, is chiefly composed of refuse pith, which smells pestilently as it becomes sour. In this half-liquid, yellowish refuse, and the black sludge of the forest, the natives trudge about, knee-deep in mire, and of course bare-legged, often badly wounded in the feet with the great spines of the leaf-sheaths, which are scattered all around. The swamp in the neighbourhood of the sago-makers is generally thick with palms overgrown with huge creepers; dark and gloomy, except

where the felling of a palm or two lets in the fierce sun, when the native works under shelter of a palm-frond supported on stakes. The atmosphere is hot and steamy, and most days there are heavy showers, whilst the mosquitoes are very troublesome, as the writer found when making these sketches; and they seemed to annoy the natives equally.

The whole apparatus of the sago-makers is wonderfully rude, and yet remarkably effective. There is nothing used in its construction but what grows at hand in the forest. The conical water bucket is made of a piece of leaf-sheath of the sago-palm softened by soaking in water, and sewn together with split rattan. The baskets for pith and jars for finished sago are made of young sago-leaves sewn together with little strips of the leaf-ribs and hooped with the same useful fibre. The adze with which the pith is scooped out of the trunk is of bamboo, strengthened with rattan bindings, and cut squarely across so that the cutting edge is blunt, not V shaped; it therefore keeps its edge longer than a steel tool would, besides rendering



Sago-makers' Tools.

the pith in just the proper condition for extracting the starch. In other parts of Ceram, stone adzes with wooden hafts are in use to-day as they were when Wallace wrote on sago-making in his "Malay Archipelago."

Once built, the *gutti* lasts a long time, and it is very common to see the various stakes and poles used in the rude structure sending forth vigorous shoots and leaves.

The prepared sago is usually baked into small cakes about four by three inches and an inch thick, in a little clay oven with about half-a-dozen slits; the powdered sago is dried and deodorised in the sun for a day or two, then sieved, and again spread out to dry. The powder is then filled into the slits of the oven, which has been previously heated almost to a dull red, face down over a wood fire. The upper side is then covered with plantain leaves, and in a few minutes the cakes are ready. They cost a cent each (about a farthing) in the Malay markets, and keep indefinitely, and are therefore much used on the Malay praus for their long sea voyages. J. C. K.

THE MAIZE PLANT.

Professor F. L. Stewart, of Murrysville, Pa., has been for many years studying the possibilities of the maize plant. Ten years ago it was demonstrated that, with suitable treatment, the plant takes equal rank with the sugar cane and the beet as a sugar producer. Professor Stewart's theory was that, as the maize plant belongs to the same botanical family as the sugar cane, and contains a fair amount of sucrose in its normal condition, it might be cultivated so as to increase its sucrose content up to the point where it would become profitable to work. He discovered, in the course of his experiments, that if the ears were removed at a certain period before the plant would normally cease growing, the period of growth would be increased by from four to six weeks, and during that time the anatomical structure became radically changed. The plant increased in size and weight; the saccharine content increased to more than double its normal amount, with a purity far above that of the natural juice, while the fibre or bagasse furnished material for paper-making of a very high grade. Experiments conducted in some twenty different States during the last few years have confirmed the results obtained at Murrysville.

In a recently-issued statement Professor Stewart estimates the products of maize treated according to his process as follows:—

A ton (2,000 lbs.) of corn cane produced under the Stewart patents, contains an average of 570 lbs. perfectly dry solid matter, and of this, 270 lbs. are in solution in the juice. Of this dissolved matter an average of 240 lbs. per ton is sucrose, 20 lbs. uncrystallisable sugar, and 10 lbs. organic matter not sugar. The average yield of dry crystallised sugar is—

First sugar 96° centrifugal . . .	160 lbs.
Second sugar 89° centrifugal . . .	30 lbs.
Total . .	190 lbs.

About six gallons of molasses, containing about 70 lbs. of uncrystallisable sugar, remain as a by-product which is converted into ethyl spirits producing 5·18 gallons of 95 per cent. alcohol.

A ton of trimmed stalks produces also, when milled and dried, about 300 lbs. of air-dry fibre, which gives about 200 lbs. of dry bleached paper pulp. The average weight of the leaves per acre is approximately one ton, and contains about 300 lbs. of air-dry fibre, or 200 lbs. of finished paper pulp.

In one ton of green ear and husk product there is about 580 lbs. of dry substance, of which 420 lbs. is fermentable matter, 85 lbs. of dry pulp and about 30 lbs. of corn gluten. The fermentable matter will yield half its weight (210 lbs.) for 31·1 gallons of 95 per cent. alcohol. In that portion of the corn belt where a suitable climate and soil can be secured, an average of twenty-five tons, gross weight, of several varieties of corn can ordinarily be grown per acre. Of this fifteen tons are stalks and ten tons green ears and husks.

To summarise, the yield of all products is as follows:—

SUGAR.

First sugar 96°—	
160 lbs. × 15 tons per acre . . =	2,400 lbs.
Second sugar 89°—	
30 lbs. × 15 tons per acre . . =	450 lbs.
Total . .	2,850 lbs.

ALCOHOL.

From ear and husk, fermentable matter—	
210 lbs., or 31·1 galls., 95 per cent. alcohol × 10 tons per acre. . =	311 galls.
From molasses produced from one ton of corn cane—	
35 lbs., or 5·18 galls., of 95 per cent. alcohol × 15 tons per acre. . =	77 galls.
Total . .	388 galls.

PAPER PULP.

Stalk and leaf product—	
213⅓ lbs. per ton × 15 tons per acre . . . . =	3,200 lbs.
Ear and husk pulp, 85 lbs. × 10 tons per acre . . . . . =	850 lbs.
Total . .	4,050 lbs.

The large amount and value of the by-products, the low cost of producing the corn crop, and the extent of territory adapted to its cultivation, all point to the conclusion that the United States can secure from this source all the sugar and paper pulp needed for domestic consumption.

During the past season demonstration tests have been conducted on the Hungarian State Experimental Station, in the extreme north of the country, and the results were so satisfactory that the Chief Chemist of the Agricultural Department is to deliver a special lecture on the new treatment at Buda-Pesth. Even better results may, of course, be expected further south, and in tropical and subtropical countries generally.

PREVENTION OF FLOODS IN THE LAKE OF LUGANO.

An important scheme for regulating the discharge of the flood waters of the Lake of Lugano will shortly be carried out, under the auspices of the Italian and Swiss Governments, who have agreed to defray the cost of the undertaking.

Considerable damage is frequently done by floods to the low-lying lands on the shores of the lake, while serious inconvenience is also caused to the traffic at these times by the roads being in places under water, and communication between the various towns and villages interrupted.

Even the St. Gothard Railway in places is at times under water. This line crosses the lake between Melide and Bissone, on a stone viaduct about half a mile in length. In floods the headway of the arches is so reduced as to stop navigation. With a flood level of two metres (six feet six inches) above the zero on the gauge, even the quays at Lugano are under water, whilst access to the various steamboat-piers is impracticable.

The Lake of Lugano, which has an area of about twenty square miles, is situated partly in Swiss and partly in Italian territory, at a level of 250 feet above the Lago Maggiore, into which it discharges near Luino by means of the River Tresa, at a distance of about eight miles from Ponte Tresa, situated near the western arm of the first-mentioned lake.

The maximum discharge from the lake during the flood of 1896 (the highest recorded) was 600 cubic metres (132,071 gallons) per second, and the minimum falls sometimes as low as four cubic metres (880 gallons) per second.

The level of the highest flood was two metres eighty centimetres above zero on the gauge, whilst the lowest level reached during droughts has been fifteen centimetres below zero, showing a range of three metres five centimetres (ten feet) between flood and drought levels.

In order to remedy this state of things, and to utilise the volume of water for motive power, it is proposed to build a weir at Ponte Tresa, provided with the necessary sluices for controlling the flow of water into the River Tresa, the channel of which will be widened and rectified.

By means of this weir the surface of the lake will be maintained between the levels of ten centimetres and one metre eighty centimetres above zero, allowing thus a range of one metre seventy centimetres (five feet eight inches) for storage purposes, whilst the maximum high-water level will be kept one metre below the highest flood level that has ever been reached.

The regulation of the floods in the Lago Maggiore and Lake of Como is also contemplated by the Italian Government at some future date.

HOME INDUSTRIES.

Anthrax Sterilization.—For many years the terrible scourge of anthrax has levied toll of human and animal life, and until recently it was believed to be an incurable disease. Now, however, it seems permissible to hope that human beings may, to a certain extent, be saved even when in the actual grip of the malady. It is claimed that by the Symons-Jones anthrax sterilization method the anthrax-infected materials imported into this country may be disinfected without impairing their usefulness for the various manufacturing processes which they subsequently undergo. The difficulty in solving the problem of anthrax sterilization has rested hitherto in discovering a method of sterilizing the anthrax spore when embedded in a gelatinous, albuminous, or other colloid body, without injury to the material or fabric to be disinfected. The materials which act as carriers of anthrax are: hides and skins (especially when dry), wool, horse-hair, mohair, rags, etc. Any process which sterilizes

hides and skins will naturally be applicable to their products, so that the adoption of a satisfactory method for the former may be assumed to solve the difficulties in the latter and all other similar cases. But the method must not interfere with any subsequent operation through which the disinfected material has to pass. The usual place of secretion of anthrax spores is on the surface of and immediate inside of a colloidal albuminous mass, such as a blood clot, and the outer "skin" of the spore consists of similar albuminoid matter. The difficulty up to the present has been to obtain a disinfecting solution which would penetrate firstly the dried blood clot, and secondly the hard "skin" (cell wall) of the spore. The treatment with acid solution provides a way out of this difficulty, for it causes the clot and the spore to swell, absorb water, and become very soft and tender. The acid itself has a deleterious effect on the spores, but sterilization by it alone is not sufficient. The process provides for this by treating swollen and tender material with a very dilute solution of a most powerful bactericide.

Railway Accidents.—Recent railway accidents have deepened the impression that the railway companies have been over-slow in adopting up-to-date means of control. In many signal-boxes the instruments which control the trains are said to have been in use a good many years, and to have been put in when railways were very different from what they are to-day. It cannot be well that the lives of passengers should be in the hands of one man who, however competent he may be, is not immune from human failings, when there are means by which he can be automatically protected from the possibility of error. A correspondent recalls that in America, in Australia, and on the London Underground, the signalman in some cases does not see the trains during the time he is on duty; yet not only are they safe, the signalman is absolutely prevented from making a mistake, for the train controls the man, and not the man the train, as far as the possibility of a wrong movement is concerned, by means of what is known as the track circuit. Had this system been in operation in the Willesden case, and the signalling instruments under track circuit control, and coil locks on the signal levers, controlled through the same track, it would have been impossible for the signalman to have admitted the other train, or have moved the wrong signal lever. In the Hawes Junction case, had the instruments been under the same control, and the signals put to danger by the engines by means of a mechanical contrivance, not only would the signal have been at danger for the express, but the fact of the engines being on the line would have prevented the signalman from accepting the express, or with a coil lock track controlled he would have been unable to pull the lever off again till the engines were clear of the section. There is one way to prevent these accidents, that is to have power-worked signals at all junctions, track circuit controlled throughout and where signals are mechanically operated, track circuit control of the instruments, and coil locks which should be fixed on all signal levers, with mechanical replacer on all main line signals.

Raw Cotton.—The expectation that the present high price of cotton will lead to a great extension of the cotton acreage in the southern states of America does not seem to rest on any solid foundation. In fact, the production of cotton there is not keeping pace with the increased demand for cotton goods. On the contrary, the growth of maize is rather encroaching on the growth of cotton in America. At current prices it pays the farmer in the southern States better to grow maize than to grow cotton. It becomes, therefore, increasingly important to encourage the cultivation of cotton elsewhere. Last week Sir Percy Girouard, the Governor of the British East Africa Protectorate, addressed a special meeting of the Council of the British Cotton-Growing Association at Manchester on the subject of cotton-growing in East Africa and Uganda, but more especially in the Protectorate. We are promised from Uganda in a short number of years something like 15,000 bales of upland American variety, whilst in the Protectorate there are large areas of land apparently eminently suitable for cotton-growing, but there are practically no natives on the land. Sir Percy Girouard says that the valleys of the Juba and Tana rivers are specially suitable for cotton-growing, and that on the British side of the Juba, which is the frontier line between British and Italian territory, there are about half a million acres suitable for irrigation. The Governor does not think that the labour question will be a very difficult one. At present the plantations on the coast have no difficulty in obtaining labour at very reasonable rates from the highlands of East Africa, where there are several million natives. But cotton-growing in the Protectorate cannot be developed properly by small men, and the Governor suggests that it should be made the subject of a scheme by means of irrigation on a large scale, such as has been suggested for the Sudan. The British Cotton-Growing Association is ready to render all possible assistance, and they have promised to join in experimental work. Assuming such work supports the conclusion that cotton-growing in the Protectorate can be made commercially successful, it will be for the general investor to find the large capital that will be required to utilize the whole of the cotton area. Obviously it would be unreasonable to expect Lancashire, with her immense and expanding industries, to finance, unaided, great schemes of cotton development in distant dependencies.

Iron-Ore Deposits.—It is stated that a strong English company has secured large iron-ore deposits in Brazil with the object of mining and shipping them to this country on a big scale. The

property so secured is at Itabiro do Matto Dentro, in the State of Minas Geraes, and it is said to contain some 60 to 70 million tons of ore, and will, in the opinion of experts, be found eventually to contain anything from 500 million to 1,000 million tons of ore. As to the quality of ore, it is said that "many millions of tons run from 69·3 to 69·8 per cent. of iron, 0·10 per cent. of silica, 0·004 to 0·01 per cent. of phosphorus, and 0·016 per cent. of sulphur, with almost no moisture. This is practically pure iron oxide." The extension of the railway to the mines, a distance of about thirty miles, has already been arranged, and the contract for the electrification and the equipment of the line, to carry a minimum of two million tons a year to the coast, has been given to a British firm. Estimates of the cost of landing the ore here are much lower than present quotations for ordinary 50 per cent. Spanish rubio. It is said that the quarrying of the ore, anyway for some time to come, will be a very simple work, and the estimated cost of putting it on waggons is between 1*s.* and 1*s.* 9*d.* per ton.

The Year's Trade.—The figures of our foreign trade in 1910 are a very agreeable study. Although the internal trade of the country is of much greater value and magnitude than the foreign trade, without the foreign trade the internal trade would not be large, for the expansion of the internal trade of the country is largely governed by the volume of our foreign trade. Expansion of our foreign trade means that the people are better able to obtain from abroad the food and raw materials required for their maintenance and prosperity. In 1910, the value of the net imports reached £574,664,000, or nearly £13 per head of the population. In an interesting article on our foreign commerce, the *Statist* points out how greatly the improvement that has come over the country is due to the renewed enterprise of our investors in using their capital for increasing the world's supplies of food and raw materials. In 1900, the value of the exports of British goods was £291,000,000; in 1910, it reached £430,000,000, an expansion in a single decade of £139,000,000, or 47 per cent. And this increase in value is not due to a rise in the price of our products, for prices in 1910 were slightly lower than prices in 1900. The increase in the quantity of British goods exported in 1910 in comparison with 1900 was 48 per cent. This great increase in the export trade of the country would have been impossible had not a great deal of capital been invested in British industries as well as an unprecedented investment of British capital in other countries for increasing the world's supplies of food and raw materials. "It cannot," says the *Statist*, "be too clearly understood that when we do not invest abroad we not only make no provision for our future supplies of food and raw materials, but we also make relatively little provision for an increased output of manufactured goods in this country, and that we use our new capital for the provision of luxuries which tend to diminish rather than to increase the well-being of the nation."

The Miners' Eight Hours Act.—It is understood that the Home Secretary will receive a deputation, representing the Miners' Federation of Great Britain, for the purpose of discussing the working of the Eight Hours Act. It is complained that in some districts there is a systematic evasion of the Act, and the Home Secretary will be urged to take legal proceedings against the offenders. The Welsh miners will urge upon Mr. Churchill the necessity for an amendment of the Act in directions where it has been found to cause dissatisfaction amongst the men employed on "shifts." It is perhaps too soon to speak with confidence upon the working of the Act, but, whether right or wrong, in the opinion of many well competent and placed to express an opinion, it is doing more harm than good.

GENERAL NOTES.

INTERNATIONAL HYGIENE EXHIBITION, DRESDEN, 1911.—Probably in no direction have greater strides been made than in the science of hygiene in the time which has elapsed since the "Exposition Internationale d'Hygiène et de Sauvetage" was held at Brussels in 1876; and it is expected that the Exhibition, to be opened in Dresden in May next, will present a complete record of the achievement of hygiene up to the present day. In view of the importance of the occasion —arrangements having already been made for over two hundred conferences and congresses in which all the great sanitary experts of the world will take part—a special interest attaches to the appeal, signed by Sir Thomas Barlow, President of the Royal College of Physicians, and Lord Ilkeston, on behalf of the British Executive Committee of the Exhibition, in which the sum of £10,000 is asked for, in order to secure the proper representation of this country at Dresden. In the spring of 1910 the German Government issued an invitation to the Governments of all the chief States of the world to take part in the Exhibition, and Great Britain is the only important Power by whom the invitation was not officially accepted. There is, therefore, a grave danger that this country, the admitted leader in hygienic science, may be the only nation of importance which is not represented. The Governments of France and Russia have each voted £20,000, while the Japanese Government has allocated £35,000 for the purpose; and it is earnestly to be hoped that the British Executive Committee will receive the sum for which they ask at the earliest possible date. Subscriptions should be sent to the Secretary of the Committee, 47, Victoria-street, S.W.

UNIVERSAL RACES CONGRESS.—The first Universal Races Congress will be held in the central building of the University of London, South Kensington, from July 26th–29th, 1911. The object of the Congress will be to discuss "the general relations subsisting between the peoples of the

East and those of the West, between so-called white and so-called coloured peoples, with a view to encouraging between them a fuller understanding, the most friendly feelings, and a heartier co-operation." Papers will be read and discussions held on the following subjects:—1. Fundamental Considerations — Meaning of Race and Nation. 2. General Conditions of Progress. 3. Peaceful Contact between Civilisations. 4. Special Problems in Inter-Racial Economics. 5. The Modern Conscience in Relation to Racial Questions. 6. Positive Suggestions for Promoting Inter-Racial Friendliness. The Congress has already aroused widespread interest. Among its supporters, who represent some fifty countries, are twenty-five Presidents of Parliaments, the majority of the Members of the Permanent Court of Arbitration and of the Delegates to the Second Hague Conference, twelve British Governors, and eight British Premiers, some hundred and thirty Professors of International Law, and the leading Anthropologists and Sociologists. The Council of the Royal Society of Arts have also intimated their willingness to promote in any way in their power the objects of the Congress. Further particulars may be obtained of Mr. G. Spiller, Hon. General Secretary, 63, South Hill Park, London, N.W.

PROCEEDINGS OF THE PHYSICAL SOCIETY.—In order to secure the more prompt publication of papers read before the Physical Society of London, the Council have decided henceforth to issue the "Proceedings" in five parts, at two-monthly intervals, during each session, and they hope it may be possible later on to issue ten parts at monthly intervals. The publications will be on sale at the Publishers to the Society, *The Electrician* Printing and Publishing Co., Ltd., 1, 2, 3, Salisbury-court, Fleet-street, London, E.C.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 25.—HORACE M. WYATT, "Motor Transport in Great Britain and the Colonies." The Hon. RICHARD CLERE PARSONS, M.A., Vice-President of the Society, will preside.

FEBRUARY 1.—PHILIP JOSEPH HARTOG, M.A., B.Sc., "Examinations and their bearing on National Efficiency." The EARL OF CROMER, G.C.B., O.M., G.C.M.G., K.C.S.I., C.I.E., Vice-President of the Society, will preside.

FEBRUARY 8.—Captain A. J. N. TREMEARNE, B.A., D.Anth., "Some Nigerian Head-Hunters."

FEBRUARY 15.—GEORGE A. STEPHEN, "Modern Machine Book-binding." JOHN MURRAY, J.P., D.L., F.S.A., will preside.

FEBRUARY 22.—Professor J. WERTHEIMER, B.Sc., B.A., "Water-Finders."

MARCH 1.—Dr. LEONARD HILL, F.R.S., "Caisson Sickness and Compressed Air."

MARCH 8.—JAMES CANTLIE, M.A., M.B., C.M., D.P.H., "Plague and its Dissemination." Sir SHIRLEY FORSTER MURPHY, M.R.C.S., will preside.

Wednesday afternoon, at 4.30 o'clock:—

MARCH 15.—Colonel CHARLES EDWARD CASSAL, V.D., F.I.C., "The Adulteration of Food." The Right Hon. the Lord Mayor of London will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 9.—R. A. LESLIE MOORE, I.C.S. (retd.), "Indian Superstitions." Lord LAMINGTON, G.C.M.G., G.C.I.E., will preside.

MARCH 16.—CLAUDE HAMILTON ARCHER HILL, I.C.S., C.S.I., C.I.E., "Education in India."

APRIL 27.—Sir THOMAS HENRY HOLLAND, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord AVEBURY, D.C.L., LL.D., F.R.S., will preside.

MAY 25.—W. R. H. MERK, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

JANUARY 31.—F. DOUGLAS OSBORNE, M.Inst.M.M., "The Tin Resources of the Empire." Sir WILLIAM HOOD TREACHER, K.C.M.G., will preside.

FEBRUARY 28.—The HON. SIR RICHARD SOLOMON, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "The Resources and Problems of the Union of South Africa."

APRIL 4.—Captain R. MUIRHEAD COLLINS, C.M.G., "Australia and her Resources."

MAY 9.—F. WILLIAMS TAYLOR, "Canadian Banking."

CANTOR LECTURES.

Monday Evenings, at 8 o'clock:—

FREDERICK WEDMORE, "Etching." Two Lectures.

Syllabus.

LECTURE I.—JANUARY 23.—"The Old Masters." The Cradle of great Etching—Rembrandt's place—Ostade and Bega—Vandyke—Landscape and Animal Subjects in the Low Countries—The Classic Landscape — Claude — Links with the Moderns—Etching no "Minor Art."

LECTURE II.—JANUARY 30.—"Modern Etching." Goya—Wilkie and Geddes—The Silence before the Revival—The great French Outburst—Méryon, Bracquemond and Jacquemart — Haden and Whistler—Themes mainly Landscape, Portraiture, Architecture—The Etching of To-day.

Professor ADRIAN J. BROWN, M.Sc., "Brewing and Modern Science." Four Lectures.

Syllabus.

LECTURE I. — FEBRUARY 6. — Introduction. Dr. Graham's Lectures Thirty-seven Years Ago—The Brewing Process a succession of Complex Bio-chemical Changes—Barley: Classification of types used by the Maltster—Barley from the Agriculturist's and Brewer's Points of View—Present Position of Knowledge regarding Characteristics of Malting Barley—Results of recent Experiments on Barley Cultivation in Ireland, etc.

LECTURE II.—FEBRUARY 13.—"Malting." Constitution of the Barleycorn — Character of Changes during Germination—Investigations of the Biochemistry of Germination—The Barleycorn a highly-specialised seed, etc.

LECTURE III.—FEBRUARY 20.—"The Mashing Process." The Chemistry of Starch and its Transformation Products—Protein Changes during the Mashing Process.

LECTURE IV.—FEBRUARY 27.—"The Fermentation Process." Previous Treatment of the subject by Dr. G. Salamon in 1888—The Pure Yeast Question in Brewing—Zymase and Modern Views of Alcoholic Fermentation—Nitrogen Assimilation—The so-called "secondary" products of Fermentation, etc.—Conclusion.

Professor J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

March 6, 13, 20, 27.

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

Dates to be hereafter announced:—

FRANK M. ANDREWS, "Architecture in America."

ARTHUR CHARLES DAVIS, F.C.S., Assoc.Inst.C.E., "The Manufacture and Testing of Portland Cement."

GEORGE B. HEMING, "Art Education in Jewellery and Goldsmithing."

Professor RAOUL PICTET, "Les Basses Températures."

Sir WILLIAM ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

HAL WILLIAMS, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

NOEL HEATON, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 23...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. F. Wedmore, "Etching." Lecture I.—"The Old Masters."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. W. R. Baldwin-Wiseman, "The Conservation of our National Water Resources."

Victoria Institute, 1, Adelphi-terrace, W.C., 4.30 p.m. Rev. A. R. Whately, "The Demand for a Christian Philosophy."

London Institution, Finsbury-circus, E.C., 5 p.m. Professor Walter Raleigh, "Hazlitt."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. T. Fyfe, "Germany and the Germans."

British Decorators, Painters' Hall, Little Trinity-lane, E.C., 8 p.m. Mr. J. Sibthorpe, "Our Visit to the Rhineland."

TUESDAY, JANUARY 24...Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. W. Mott, "Heredity." (Lecture II.)

Brewing, Institute of (Scottish Section), Caledonian Station Hotel, Edinburgh, 7.45 p.m. Mr. H. W. Harman, "Practical Notes upon (1) Influence of Air upon Malting and Brewing, and (2) Brewing Value of Hops."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. C. W. King, "Sand-Movements at Newcastle Entrance, N.S.W." 2. Mr. C. S. R. Palmer, "Fremantle Harbour-Works, Western Australia." 3. Mr. G. H. Halligan, "The Bar Harbours of New South Wales."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. F. Stanley, "The Photography of Spectra, with Notes on the New Féry Spectrograph."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. The Hon. J. G. Jenkins, "Papua and the Papuans."

WEDNESDAY, JANUARY 25...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. H. M. Wyatt, "Motor Transport in Great Britain and the Colonies."

Geological, Burlington House, W., 8 p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Mr. W. Cobb, "The Nelson Touch."

Royal Society of Literature, 20, Hanover-square, W., 5 p.m. Professor M. A. Gerothwohl, "The Englishman in the Eighteenth Century French Drama."

Mining and Metallurgy, at the Institution of Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. 1. Discussion on Mr. H. C. Bayldon's paper, "Notes on Chilian Mills in Russia." 2. Mr. N. A. Loggin, "Notes on Placer Mining, with Special Reference to Hydraulic Sluicing."

THURSDAY, JANUARY 26...Electrical Engineers, Victoria Embankment, W.C., 8 p.m. 1. Mr. W. T. Taylor, "Long Distance Transmission of Electrical Energy." 2. Messrs. R. Borlase Matthews and C. T. Wilkinson, "Extra High Pressure Transmission Lines."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Child Study, 90, Buckingham Palace-road, S.W., 7.30 p.m. Mrs. M. Scharlieb, "Recreational Activities of Girls during Adolescence."

London Chamber of Commerce, Skinners' Hall, Dowgate-hill, E.C., 2.30 p.m. Address by Sir George H. Reid, "Australia—the 123rd Birthday of the Empire's only Continent."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. O. Bradley, "Mignon's Song."

Royal Institution, Albemarle-street, W., 3 p.m. The Astronomer-Royal, "Recent Progress in Astronomy." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. A. H. Blake, "History in Caricature and Satire."

Brewing, Institute of (Midland Counties Section), White Horse Hotel, Congreve-street, Birmingham, 7 p.m. Dr. A. Slator, "The Rate of Alcoholic Fermentation."

FRIDAY, JANUARY 27...Royal Institution, Albemarle-street, W., 9 p.m. Professor W. H. Bragg, "Radioactivity as a Kinetic Theory of a Fourth State of Matter."

North-East Coast Institution of Engineers and Shipbuilders, Newcastle-on-Tyne, 7.30 p.m.

Physical, University College, Gower-st., W.C. (Physics Lecture Theatre), 5 p.m. 1. Professor F. T. Trouton, "A Demonstration of Phase Difference between the Primary and Secondary Currents of a Transformer by means of a Simple Apparatus." 2. Professor J. A. Fleming, "A Note on the Experimental Measurement of the High Frequency Resistance of Wires." 3. Professor J. A. Fleming and Mr. G. B. Dyke, (a) "The Measurement of Energy Losses in Condensers traversed by High Frequency Oscillations." (b) "Some Resonance Curves taken with Impact and Spark Discharges."

SATURDAY, JANUARY 28...Royal Institution, Albemarle-street, W., 3 p.m. Mr. Arthur Hassall, "Problems in the Career of the Great Napoleon." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,036. VOL. LIX.

FRIDAY, JANUARY 27, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 30th, 8 p.m. (Cantor Lecture.) FREDERICK WEDMORE, "Etching." (Lecture II.—"Modern Etching.")

TUESDAY, JANUARY 31st, 4.30 p.m. (Colonial Section.) F. DOUGLAS OSBORNE, M.Inst.M.M., "The Tin Resources of the Empire." Sir WILLIAM HOOD TREACHER, K.C.M.G., will preside.

WEDNESDAY, FEBRUARY 1st, 8 p.m. (Ordinary Meeting.) PHILIP JOSEPH HARTOG, M.A., B.Sc., "Examinations and their bearing on National Efficiency." The EARL OF CROMER, G.C.B., O.M., G.C.M.G., K.C.S.I., C.I.E., Vice-President of the Society, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday Evening, the 23rd inst., Mr. FREDERICK WEDMORE delivered the first lecture of his course on "Etching."

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, January 19th; Sir FELIX SCHUSTER, Bart., in the chair. A paper on "Banking in India" was read by Mr. REGINALD MURRAY, formerly Manager of the Chartered Mercantile Bank of India, London and China, in the Straits Settlements and India.

The paper and discussion will be published in a subsequent number of the *Journal*.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

SEVENTH ORDINARY MEETING.

Wednesday, January 25th, 1911; The Hon. RICHARD CLERE PARSONS, M.A., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Daneff, St., LL.D., Sofia, Bulgaria.

Forman, Robert Brodie, High Pastures, Elmswood-road, Aigburth, Liverpool.

Gunn, Donald, Hogtrow, Hook Heath, Woking.

Hudson, Philip Reginald, A.R.S.M., 807, Majestic-building, Denver, Colorado, U.S.A.

Lal, Pyarai, Zamindar of Burotha, Aligarh, India.

Schoenfeld, L. S., 807, Majestic-building, Denver, Colorado, U.S.A.

Shamasastry, R., B.A., Government Oriental Library, Mysore, India.

Simkins, Arthur C., M.E., 807, Majestic-building, Denver, Colorado, U.S.A.

Tattersall, Alfred Rishworth, 75, Mark-lane, E.C.

Vernon, Arthur Longley, 10, Abbey-road, St. John's Wood, N.W.

Whiteley, Richard H., National State Bank Block, Boulder, Colorado, U.S.A.

Worsham, Ernest Lee, State Board of Entomology, Atlanta, Georgia, U.S.A.

The following candidates were balloted for and duly elected members of the Society:—

Borthwick, Miss Jessica, 33, Rue du Jardin, Ostend, Belgium.

Eastburn, Mrs. Adelaide, 14, Ravenscourt-mansions, Hamlet-gardens, Ravenscourt-park, W.

Haslehust, Ernest W., 72, Burnt Ash-hill, Lee, S.E.

King, Alexander Freeman, C.B., 44, Foxgrove-road, Beckenham.

Miles, George W., 29, Central-street, Boston, Massachusetts, U.S.A.

Mylcrist, Captain Stanley, 560, Sunder-road, Karachi, India.

Wigram, Reginald, J.P., M.Inst.C.E., Chapel Allerton, Leeds.

The paper read was—

MOTOR TRANSPORT AT HOME AND IN THE COLONIES.

By Horace M. Wyatt,
Editor of "Motor Traction."

In the course of this paper the author will attempt to indicate more particularly the enormous field which exists in Greater Britain for the mechanically-propelled road vehicle, and the influences which have operated, and will operate, for or against the more extensive use of motor traction, not only in this country, but throughout the Empire. In order to deal with this complex subject without unnecessary confusion, the paper is divided into sections treating of different phases of development and prospects.

In the first place, it is abundantly necessary to explain, more especially for the benefit of those resident in distant countries, how outside causes, not intimately connected with the design of the vehicles themselves, contributed towards those early failures which were undoubtedly very numerous. We, who are on the spot, are in a position to realise quickly enough when failure has turned to success, but such realisation comes but slowly to those who have to depend largely for their information on visitors from this country, and on rumour which percolates to them through sources not invariably reliable. In tracing the progress that has been made and the causes which have assisted in overcoming prejudices against motor vehicles for business purposes, and in establishing them as an essential of the traffic of the future, it may be advisable to treat of certain specific instances of a typical nature.

After having shown how satisfactory is the position which the industrial motor vehicle is now steadily attaining in this country, the next step is to consider what modifications in design are usually needed to fit the products for the markets of Greater Britain. In this section it is necessary to touch on the relations between the British manufacturer and the colonial buyer. These relations, unfortunately, do not always show as much mutual respect and good feeling as might be wished. That faults exist must be admitted, but I shall hope to show that such faults are not all on one side, and that much of the attitude of the British manufacturer, which is often made to appear as unduly conservative and unprogressive, will, in fact, be seen, if given broad consideration, to be of real benefit to progress.

It is, of course, useless to consider the production of vehicles specially suited for use in the colonies unless there is a likelihood of a real demand sufficient to justify the standardisation of types. The question of local demand throughout the Empire is therefore dealt with in an appendix, for the contents of which the author is almost wholly dependent on information received from a very large number of correspondents resident in Greater Britain.

Lastly, it seems advisable to consider not only how the trade between the Mother Country and the colonies may be allowed to grow, but how that growth might be accelerated in a legitimate and useful manner, and under this heading a few suggestions are put forward, which, it is hoped, will at least be thought worthy of consideration, and possibly of discussion.

With these prefatory remarks, I will now turn to the first section of my paper, and attempt to deal as completely as possible in the limited time at my disposal with the matters outlined above.

Section I.—Early Failures and Recent Successes.

Those who trifle with the laws of Nature always find sooner or later that they must pay the penalty. One of these laws is that growth and progress shall be gradual, and that, though they may be accelerated by artificial means, any such acceleration leads to weakness or early decay. A good example of this is afforded by the produce of the land. Admittedly, earlier fruits can be obtained by means of hot-houses or intensive culture, but plants which have been so treated will undoubtedly suffer in hardiness and in their capacity to stand the normal climatic conditions of the country. The law holds good equally in the case of a new industry, and in almost every phase of progress those who have pushed ahead too fast have found this out to their cost.

The fact that the motor vehicle might be made into a really practical implement for more heavy work than mere touring and enjoyment was realised so suddenly that it almost amounted to a revolutionary discovery. No sooner had it been shown that mechanical haulage might be employed for omnibuses, for vans, and for lorries, than there was an indiscriminate rush to be amongst the first to reap the benefits, which it was rightly foreseen must sooner or later accrue. As is usual in such a case, the result was that the new implement was put to uses for which it was totally unsuited, and was designed

constructed, or adapted with a haste which prohibited thoroughness.

The Progress of the Public-Service Motor.—To trace the causes of early troubles in the motor traction movement with any fairness, it is essential to separate the various classes of vehicle and to consider them individually. Motor omnibuses afford, perhaps, the most striking example of recovery from early troubles. So soon as it was demonstrated that these machines were economically possible, there was a mad scramble to place them upon the streets before competitors could do likewise. Even then a few, but very few, manufacturers had studied the question sufficiently to produce a sound chassis. These were bought up almost instantaneously, and orders for scores and even hundreds went begging in the open market. The result was inevitable. Manufacturers with insufficient experience saw opportunities for quick sales and substantial profits. Continental firms were very willing to step into the breach left by the rather deliberate but eminently responsible British manufacturer. The streets were flooded with the first thing on which the company promoters could lay their hands. Many of these gentlemen themselves, concerned not at all with the mechanical aspect of the question, and to no great extent with the ultimate welfare of the ordinary shareholders, saw in the motor omnibus simply an opportunity for a "boom," which might well leave promoters the better off, whatever its effect on all others concerned. In many cases the vehicles, unsuitable in themselves and difficult enough to run with any satisfaction, were put into the charge of engineers who did not understand the problem with which they were faced, and who had behind them the doubtful support of directors who could not realise that a mechanical vehicle, like any other machine, requires regular supervision and adequate attention. Garages and repair shops were poorly staffed and insufficiently equipped, and the vehicles were wanted upon the road at every conceivable moment to earn the maximum of money in the minimum of time. For the moment the public rejoiced in the increased speed of the new conveyances, laughed in a good-humoured way at their failings, and bore them no particular ill-will for their defects.

Temporary Unpopularity.—Presently, however, people had time to look at the development of the new traffic more carefully. They realised that if the thing were to exist at all it would sooner or later become universal, and that whatever drawbacks it might bring with it would have to be considered seriously, and not merely as fit subjects for humorous drawings. Public opinion is always inclined towards extremes, and from an enthusiastic welcome it veered round somewhat suddenly, and—influenced perhaps a by few unfortunate accidents—changed from friendliness to disgust. In so doing it was helped by the fact that, by this time, many of the cars had been on the road long enough to become exceedingly noisy, and drivers had grown sufficiently sure of themselves to cultivate a contempt for other forms of traffic and a desire to out-do their competitors in the matter of speed. Thus it came about that, just when operating companies had begun to realise that their work was hardly as simple as they had expected, and that they had to find the solution of many mechanical problems before their vehicles would be perfectly reliable, they were faced with further difficulties imposed through the medium of the licensing authorities. As a result, too, of their excess of zeal, competition became too severe, and fares were cut down to a basis on which it was almost impossible to show a profit. It was at this time that the impression began to get about that the motor omnibus was a failure, and, judging from letters which the writer has received even recently, the idea is still fairly rooted in many parts of the world, more especially in distant countries, to which general impressions, as distinct from mere statements, take some time to spread.

What has gone before applies perhaps more directly to London than to the country generally, but small services in provincial towns often reproduced on a lesser scale the state of affairs briefly outlined above. More especially did the promoters of these local services err owing to the belief that mechanical vehicles might be run without any adequate overhaul or attention. Many of these little concerns, possessing only small financial support, realised too late that a punctual and regular service possessed the elements of success which would not result from a haphazard and variable supply of vehicles, even though they might be more or less available for some sixteen hours of the day.

Not the least among the troubles of those interested in motor omnibuses has been the opposition of tramway interests generally and of municipal authorities in particular. There seems to be no adequate reason why the tram, as opposed to the road vehicle, should be inseparably connected with municipal enterprise. This is, however, very frequently the case, and thus the motor omnibus company found itself obliged to apply for licences to its own

competitors for traffic. With all these influences working together it is not surprising that some operating companies failed entirely, while others struggled for a bare existence instead of showing the substantial profits which had been fondly anticipated.

The Turn of the Tide.—In the last two years, however, matters have improved very materially. Companies, finding it impossible to compete so fiercely with one another, resorted to amalgamation. This not only allowed of some increase in fares, but did away with racing, which was at once a danger to the public and the cause of rapid depreciation of the mechanism of the vehicles. The companies which had not attempted too much and were properly managed and equipped began to show, beyond a doubt, that failure was not caused by the system but by its misapplication. Individuals and small concerns in town and country began to see the possibilities of profit in vehicles of the char-à-banc class, and showed that mechanically-propelled public-service carriages might be profitably worked even singly or in small numbers. The public became more and more converted to the utility of the motor omnibus, and the efforts of the licensing authorities, whilst bearing hardly upon the operating companies for a time, undoubtedly tended towards the production of a more agreeable class of vehicle.

In its annual report, published at the end of the year 1909, the London General Omnibus Co. showed a profit on the lines worked by motor omnibuses and a loss where horses were employed, and announced its intention of doing away definitely with animal traction. That this statement of policy was a genuine one has been shown by the progress which has been made since that time.

Official Confirmation of Progress.—The present state of affairs was well expressed in the report of the London Traffic Branch of the Board of Trade for 1909:—"Worn-out horse omnibuses are not being replaced; further wastage will be made good and additional demands supplied largely by adding to the number of motors. The expense of maintaining and running the latter has been reduced, and they now pay better than the others."

The experience of London has been corroborated by that of Paris. When the concessions possessed by the big operating companies of that city terminated early in 1910 they were renewed only on condition that the whole of the horsed vehicles should be replaced by motors within a limited period.

It is not only when compared with the horse that the motor omnibus is now capable of showing itself a strong claimant for notice. In certain provincial towns, as for example Eastbourne and Folkestone, the local passenger traffic demands are now met entirely, or to a very great extent, by motor vehicles, which are preferred to trams. In the report which is quoted above the following significant sentences appear:—"As rivals to tramways, motor omnibuses are likely to become more formidable than they have been hitherto. As an instrument of locomotion the omnibus is in its infancy, whereas the tramway has come to maturity. Even in the imperfect conditions that have prevailed hitherto, omnibus competition has been so effective that municipal authorities have been induced to appeal to the ratepayers to patronise their own tramways. There is, indeed much in the present aspect of the motor industry that may give pause to the promoters of tramways."

Operating Companies their Own Manufacturers.—Before considering special cases, there is one other point which deserves mention. This is the tendency of some of the large operating concerns to manufacture their own vehicles in their own works. It has certainly been shown that successful results may under certain conditions be obtained in this way, but it is necessary to warn those who may contemplate following the lead of the big companies as to certain dangers which beset their path. In the course of some five or six years' experience with a large fleet of vehicles of various types, it stands to reason that the engineers of a big operating concern gain an enormous amount of useful experience in constructional details which may well fit them to superintend the complete work of design and construction, provided that their shops are adequately equipped for the purpose. It would, however, be suicidal for an operating company without such experience to attempt its own building. For example, if a company were formed to run a large number of omnibuses in a British colony, it would be madness for it to attempt to dispense with the services of the experienced manufacturer. His experience has only been bought at a high price, both in time and money, and however clever the designers and managers of an absolutely new concern may be, the first productions cannot be made to embody all the apparently trifling and sometimes invisible results of the study and experiment of years. Operating companies which were among the pioneers in the motor traction movement had facilities which could hardly be duplicated at

the present moment for studying the strong and weak points of numerous designs, and perforce gained much bitter but valuable experience, which they can now reasonably utilise for their own benefit. New companies, if wisely directed, would not at the present day purchase mixed fleets containing a large variety of types and makes, and consequently their experience would never be so complete as that of the concerns which have gone through the mill during the most discouraging stages of development.

The London General Omnibus Co.—In taking one or two concrete examples of progress, one naturally turns first to the London General Omnibus Co., with its fleet of motor omnibuses running into four figures. In the year ending June, 1908, the separate companies which are now combined together under the title of the London General showed an aggregate loss of something over a quarter of a million, and consequently the report for the ensuing fifteen months, which showed a debit balance of £33,400, could not be held to be altogether unsatisfactory. The chairman of the premier company, when this report was issued, stated clearly that a considerable profit had been shown on the working of the motor omnibuses, and a corresponding loss on the operation of horsed vehicles, and announced that the policy of the company from that time onward would be to replace horses by motors until the whole fleet depended solely on mechanical traction. An unsatisfactory feature of the report was that no allowance had been made for depreciation, the auditors calling attention to this omission. During the last fifteen months or so, the company has continued to make progress in the reduction of the running expenses of its vehicles, and it is satisfactory to be able to record the fact that this economy in maintenance is to a large extent responsible for the satisfactory report for the year ending September, 1910. The improvement shown is certainly remarkable, a deficit of £33,400 being turned into a profit of £61,135. This allowed of the payment of full arrears of dividend on the preference shares, and had it not been for the tax on petrol, which hits the company very hard, some dividend might also have been paid on the ordinary shares. Even as it is, the steady advance which has followed the more extensive use of motor vehicles is a full justification of the motor omnibus in general, and of the policy of the company in particular. The present report is rendered all the more satisfactory by the fact that the auditors have not, as on previous occasions, called attention to any lack of allowance for depreciation or any other regular charges.

Other London Companies.—Smaller companies operating in London, as for example the Great Eastern and the Central Omnibus Companies, have been financial successes from the start, this being partly due, no doubt, to the fact that they exercised great caution during the most trying stage of the industry. The Scottish Motor Traction Co., operating in Edinburgh, has also given satisfactory results, paying a regular and reasonable dividend to its shareholders.

Provincial and Colonial Examples.—As an example of a service in a provincial town one may take the Motor Omnibus Department of the Corporation of Eastbourne. Ever since this concern came under its present management it has shown a profit on each year's working. The last report has shown a balance of some £660 as against £250 in the previous year. The latest result is the best up to date, and this fact is noteworthy, since it (and many others like it) shows that the life of a motor omnibus is longer than was anticipated in many quarters, and that the costs of operation need not go up from year to year. In Eastbourne the services are not run under ideal conditions, since the traffic receipts are very low in the winter months, and the loss then incurred has to be made up before the summer traffic can show a net profit. The winter running is to a great extent responsible for the fact that the total operating costs per mile work out to about 1*s*. 1*d*., whereas in London they can be kept down to something like 9*d*., inclusive of all possible charges.

As a final example, the motor omnibus service of the Federated Malay States Railway may be mentioned. Exclusive of depreciation, the aggregate cost per mile comes out at just over 1*s*., although the fleet is not kept really fully employed. This figure of cost shows a margin of profit of about 2*d*. per mile, of which 1*d*. might reasonably be set aside for depreciation. As a matter of fact, the company has gone to extremes in this respect, and has made a big and abnormal allowance, which gives an unfairly bad impression of the results of the year's work. It is at least interesting to note that the Federated Malay States Railway's fleet numbers almost fifty vehicles, which in itself gives some idea of the possibilities of development of road traction in connection with railways throughout the Empire.

At home many of the largest railways have very substantial fleets of motor vehicles, the

Great Western Railway being the largest users of this class. At first almost all the vehicles owned by railways were of the char-à-banc or omnibus type, but recently there has been a satisfactory tendency towards the purchase of goods vehicles, while internal-combustion rail motors are used on light railways and in districts where traffic is not fully developed or comparatively small conveyances are required. These will doubtless soon be employed, especially on colonial railways, far more extensively than they are at present.

The Char-à-banc and Waggonette.—In dealing at some length with motor omnibuses it must be pointed out that the statements made are not only applicable to the double-deck motor omnibus of the ordinary type, but, generally speaking, to all motor conveyances designed for the carriage of passengers in considerable numbers. The services of the Federated Malay States Railway, and many of those of the home railways, are worked with single-deck vehicles, as are also numerous other services, such as those in the neighbourhood of Folkestone; and, generally speaking, the demand for public-service vehicles in the colonies will be in the direction of the char-à-banc, waggonette, or single-deck omnibus, rather than the double-deck type, which is suited especially for town work. In Great Britain itself there are an enormous number of motor chars-à-bancs owned singly or in twos and threes by jobmasters, hotel proprietors, and others, and working for the most part very regularly, and with considerable profit to their owners.

The Motor Cab.—I have devoted some little time to the motor omnibus, as this class of vehicle is called upon to perform work of unexampled severity, and I think it is a foregone conclusion that if, as is actually the case, the motor omnibus is a proved success, other vehicles, such as motor cabs, vans, lorries, and all classes of trade vehicles, may be to some extent taken for granted. Before leaving the public-service vehicle altogether a few moments may, however, be given to the motor cab. The growth of this class of vehicle in the last six years has been extraordinary. At the end of 1904 there were two motor cabs in London; now there are well over 6,000, and this progress has been accompanied by an almost exactly corresponding decrease in the number of horsed cabs. In Paris the same rapid change has been taking place, and although the complete abolition of the horsed cab in provincial towns and also in colonial cities may not be quite so rapid, it is none the less certain. The period of apprenticeship of the motor cab was not as trying as that of the motor omnibus. The former, for the most part, is only a reasonable modification of the moderate-powered touring car, and there were not many new mechanical problems to be faced in its production. Neither does it seem likely that any very distinct type must be evolved for colonial use. It is undeniable that the rapid success of the motor cab is closely linked with the use of the taximeter, and it may fairly be said that the refusal of the horsed cabdrivers to adopt a reliable machine for registering the fare was a great assistance towards the progress of the motor. Naturally, there have been a certain number of complaints against taximeters on the grounds of accuracy. These, however, are in a great majority of cases unfounded. The writer has made a considerable number of road tests of taximeters of all the recognised makes, and the conclusion reached has been that, if the registration is not absolutely accurate, any error existing favours the public rather than the cab proprietor. This statement may be proved by taking journeys over distances which have been measured by the Metropolitan Police. It will be found that not infrequently the fare charged on the taximeter, registering both by time and by distance, is actually lower than the fare which would be paid if the measured distance only were considered, and the charge reckoned at 8*d*. per mile.

Vans and Lorries.—Turning to the trade vehicle proper, we find that progress has been arrested, more especially in certain districts, by reason of early failures. In many cases lack of success was due to the adaptation of unsuitable touring-car chassis to purposes for which they were never constructed. Even now one occasionally hears recommendations which will lead almost certainly to failure. Only a few weeks ago I read advice to the effect that second-hand touring cars fitted with suitable bodies would make good motor vans. In isolated instances, such experiments may have been attended with results which were far better than they deserved, but any so-called expert who could give general advice of this kind is fit only for an asylum or a reformatory, according to whether his expressed opinion is the result of sheer folly or of fraudulent intent.

Another factor which has tended to hold back the business motor vehicle was the formation of haulage and delivery companies, either operating with unsuitable vehicles or under inefficient management. Such concerns were not uncommon

in the early days of the industry, and a considerable amount of money was lost in them. Consequently we find deep-rooted prejudices still existing in certain defined areas. We are still not absolutely free from this kind of danger, for it is sometimes possible to formulate schemes which appear for the moment to be very attractive and far more likely to draw public support than more honest but less showy ventures. There is, of course, an enormous future for the genuine motor haulage and delivery contractor, and it is probable that the time will come when a very large percentage of the delivery work of great cities will be done by firms of this kind.

So far as the present position of the motor van and lorry is concerned, it will suffice to point out that huge fleets are operated by all the biggest retail stores in London and elsewhere in this country; that considerable numbers of vans are used for the carriage of mails, for which absolute reliability is the first essential; and that the motor ambulance, which must be at once smooth-running, speedy, and safe, bids fair to oust altogether the horse-drawn conveyance of the same class. It is doubtful whether there is a single well-known trade in which motor vehicles are not now employed, and the extent of their use is such that a variety of imaginary disadvantages—such as fears that perishable provisions would be injured by smell, or that fragile goods would be damaged by vibration—have died a natural death.

The Steam Lorry and Tractor.—The steam lorry and tractor have found their own spheres of usefulness almost entirely by a steady development along sound business lines. The satisfactory experience of one buyer has led to purchases by others in the same trade, and each vehicle has formed a centre around which business has grown up at a moderate rate, but none the less with certainty. The steam lorry is eminently suited for the carriage of loads of some five tons, with the addition of drawing, say, an extra three tons on its trailer. The tractor, while it has to depend entirely on its own weight for the adhesion necessary to draw its load, has the advantage that the load and the engine can be readily connected and disconnected. Thus, the engine itself can, by proper management, be kept almost constantly at work, while loading and unloading are still proceeding in the various depôts. The most recent development of the steam vehicle is in the direction of the smaller sizes. Whereas the petrol van has developed up from the light to the heavy, the steam lorry has made progress in the other direction, and the success of the five- or six-tonner has induced makers to turn their attention to the production of smaller machines, usually running on rubber tyres, and carrying two to three tons. About two and a half tons appears to be the lowest limit at which this class of machine can be advantageously employed. The steam lorry and tractor are essentially British productions, being to a great extent a natural development from the heavy road engine. So pre-eminent are British manufacturers in this particular branch, that steam lorries of English make are actually beginning to find a good market in France, where it might have been expected that the petrol vehicle would reign unchallenged. So far as economy is concerned, the steam lorry and tractor compare very favourably with any other class of motor vehicle, and—with the exception of weight of load—practically the only limitation to their use lies in the fact that they cannot carry a supply of fuel and water adequate for a very lengthy journey. In Great Britain itself this is of little consequence, but in some districts in the colonies it becomes important, and renders the production of a really economical and efficient internal-combustion tractor very essential.

General-Purpose and Agricultural Tractors.—It is a curious thing that while petrol-engined vehicles are to be found in all trades, and are in extensive use by fire brigades, municipal authorities, hospitals, and Government departments, their employment in connection with agriculture has up to the present been considerably restricted. This country is not ideal for the development of the agricultural motor and general-purpose farm tractor, which would find a readier market where land is not cut up into such small divisions. The great difficulty appears to be that a tractor with sufficient power to conduct ploughing operations at a reasonable speed in heavy land must necessarily be unduly powerful when applied to certain other subsequent operations, and it is extremely likely that its weight may be such as to make it undesirable to put it upon the land during the later stages of cultivation. The lighter class of agricultural motor is of considerable general use for farm purposes, and for driving stationary machinery, but its power is, of course, somewhat limited. Very diverse opinions reach this country as to what would really be the most suitable type of agricultural motor to meet the bulk of the colonial demand, and most British manufacturers hesitate to take up the proposition on a sufficient scale to lead to economical production

until they feel more sure of their ground. Up to the present the United States has favoured the heavier class of agricultural machine, but here, again, reports as to the actual results obtained are very conflicting. It would, I am sure, be of great interest to the British manufacturing trade if those who know the conditions of our great colonies well from personal experience would give their views on this question. For myself, I feel that, though some progress has been made, agriculture is the industry in connection with which the mechanical transport vehicle has at present reached the least satisfactory stage in its development. In saying this I do not refer specifically to the products of British makers, as I have reason to suppose that the attempts made on the Continent and on the other side of the Atlantic to solve this somewhat intricate problem have not been by any means wholly successful.

Section II.—Requirements of the Colonial Markets.

The question of special requirements is very closely linked with that of the relations between the buyer in the colonies and the manufacturer at home. As already mentioned, these relations have not always been of the sweetest, and it may be that traders in some branches have every right to complain of the dilatory methods of this country. However that may be, I cannot find sufficient evidence to show that it holds good to any reasonable extent in the particular industry under discussion. There have no doubt been a certain number of instances in which inquiries have not been treated with the full attention that they deserve, and in the early days of the industry there have doubtless been cases in which, owing to the rapid changes in design, manufacturers have been unable to supply promptly spare parts required for earlier models. We have, however, now reached a point of development when this last-mentioned difficulty should be practically non-existent.

The chief cause of ill-feeling appears to be that manufacturers are not disposed to produce a single vehicle embodying many features distinguishing it from their standard models. In some cases they may be wrong to discourage new business along new lines, but it is not always financially possible to deal with special requirements, and it is not unnatural that a manufacturer should attempt to meet peculiar demands by encouraging the purchase of more ordinary vehicles. In so doing, he is not merely consulting his own convenience, but the ultimate benefit of the purchaser. The standard model, though it may lack certain attributes, rendering it absolutely suitable for the work to which it is to be put, is at least the result of considerable experience and experiment. Every part of it has been tried and found good, and, though its utility may be limited in certain directions, it is probable that it will give better and more profitable service than a specially-constructed vehicle containing a number of purely experimental features.

Careless Correspondence.—If the manufacturer fails anywhere it is, in the opinion of the writer, in the details of his correspondence. To take a concrete example, a resident in British East Africa was recently anxiously inquiring for a suitable internal-combustion tractor for use in his district, and he was able to show that the demand for such a machine would almost certainly be very considerable. He was, however, troubled on one point, this being the question of whether special carburetter adjustment or design would be necessary if the tractor were obliged to work at very high altitudes above sea level. He laid particular stress on his wish for information on this point, but, in spite of carefully-worded inquiries, the replies received from home manufacturers universally neglected the one feature as to which he had doubts. This neglect is probably explained by the fact that the manufacturers themselves realised that the detail was comparatively an unimportant one, and that no real difficulty would arise in connection with it. Even so, the neglect to supply the information is inexcusable, and in this instance at least has led to the loss of the order, the purchaser having, somewhat against his will, decided upon a steam vehicle, which in many other respects he does not consider to be so suitable for his work. Instances of this kind seem to show that manufacturers sometimes devote the whole of their attention to the production of a first-class product, and allow the details of their sales department to be handled by inexperienced clerks, who are possibly only too anxious to get through their work in the minimum of time.

Quality of British Goods.—So far as the quality of British engineering products is concerned, there can be little or no cause for complaint in any branch of engineering, and in the motor traction industry there is absolutely no question whatever that the British market can supply the very best in all classes of industrial vehicle. Engineers who have ample experience of other countries as well as of Great Britain, and who are not biassed in any way, corroborate the view

that, so far as design and construction are concerned, this country has little or nothing to learn from the Continent, while the United States may for the present be regarded as altogether unproductive. This state of affairs will not, of course, continue; for the leading firms in the States are even now turning their serious attention to the heavier branches of the industry, and since they do not scruple to learn and adapt from British design, it is probable that, with their enormous outputs, they will become very real and serious competitors in the course of a few years. Even now the energetic business methods of American manufacturers suffice to plant cheap and generally shoddy American-built vans and lorries in many British colonies, and there is a distinct risk that the whole of the trade of Canada and the West Indies may ultimately go to the States on this account. It is, however, impossible to emphasise too strongly the real superiority of British-built vehicles over those of American origin.

Where the Buyer is at Fault.—Looking at the other side of the question, it will be seen that the potential buyer in the colonies is not altogether blameless if friction arises between him and the manufacturer. Certainly he knows something of his local conditions, but at the same time he generally knows little or nothing of the difficulties of engineering design. Consequently, he is only too apt to specify for an absolutely impossible combination of mechanical features, and to blame the manufacturer who will not quote him a reasonable price—or, still more likely, will not quote him at all—for a composite conglomeration of excellent designs and inventions which, considered as a whole, would be destined to immediate and undoubted failure when the vehicle is put into service. The British manufacturer, would as a rule, rather not do trade at all than do it in such a way as to create a bad impression of his products. He prefers to build up his business slowly and steadily by sound methods. To take an example on this side of the question, the corporation of a large town in a British colony invited tenders for a fire engine. The specification included diameter of driving wheels, ground clearance of mechanism, and a stipulation that the drive should be through a cardan-shaft and worm-gearing. The dimensions were such that a straight axle between the two driving-wheels would only just have had the necessary clearance from the ground, and no space whatever was allowed for the worm-gear and differential-gear and the casing containing them.

Buyers in distant countries should realise that a feature which may be good in itself is not necessarily good when it is imported into a design which was never intended to receive it. A Roman nose, in itself, is a more beautiful and possibly a more serviceable thing than a snub nose, but if it be put on to a face which was intended for the latter, the most beautiful Roman nose in existence will only be an æsthetic and practical failure. The same reasoning applies to the question under consideration.

Summing the matter up, the author would urge upon manufacturers at home to arrange that their correspondence should be fully and carefully dealt with by really competent men, who take proper trouble to study the letters for which their replies are intended. On the other side, he would beg all colonial buyers not to magnify the peculiarities of their requirements, which in ninety-nine cases out of a hundred are not really so different from those of other districts as to necessitate the construction of a special type of vehicle, or the embodiment of alterations very expensive both in time and in money.

Ground Clearance.—One of the principal points in which deviation from standard design is necessary, in order to cater successfully for colonial trade, is ground clearance. A clearance of, say, ten, or even eight, inches may be ample for a three-ton lorry or passenger conveyance for use at home, working exclusively—or almost exclusively—on made roads of fairly good quality. In younger countries, however, this is often insufficient in view of the rocks and tree-stumps projecting above the surface of the track. This track consisting frequently of little more than two deep ruts, the effective height of such obstructions is increased, and they become very dangerous to the mechanism. Further, it often happens that at certain seasons the ground becomes very soft, while in other districts sand abounds. In either case wheels sink deep, reducing the ground clearance of the mechanism. Then again, fords may have to be crossed, so that the engine must be placed high.

Big Wheels—Clearly, the simplest way of overcoming the difficulty from a mechanical point of view is by the adoption of big wheels with wide treads. The latter assist in preventing the vehicle from sinking in soft or sandy places, and at the same time reduce the loss of power, which is always an important factor when the wheels are perpetually climbing uphill out of the cavities into which they have sunk. The increased width gives a larger area of contact with the ground, and reduces the intensity of

pressure, and consequently the depth of the rut formed.

An increased diameter of wheel has a similar effect, but at the same time it levels out the smaller depressions in the road surface, and makes for easier riding, so rendering higher speeds possible without undue jolting, which is a source not only of discomfort to passengers, but of damage to mechanism.

In a self-contained vehicle the provision of big wheels is not, however, quite so simple a matter as might be imagined. For one thing it entails a further gear reduction between engine and driving-wheels, and this may not be compatible with sound design without the introduction of an extra reduction gear. There are limits to the reduction which can be advantageously effected in one step. For example, in the case of a chain-driven machine the maximum size of the chain-wheel is limited by the necessity for keeping the chain well clear of the ground. This limit being reached, the reduction between the sprockets on the cross-shaft and the chain-wheels can only be increased by reducing the size of the sprockets and the number of teeth upon them. If this reduction be taken too far the effect of the action of the rear springs is to cause uneven propulsion, rapid wear of sprockets and chains, and even undesirable stresses as far forward as the clutch and possibly the engine itself. This difficulty of gear reduction is, however, not insuperable, since a modification of differential or change-speed gears, and possibly the introduction of an extra reduction gear, will attain the desired object. The example is given rather to show that when extra big wheels are specified the manufacturer has not merely got to take off his standard wheels and put on larger ones, but may very likely be put to expense never contemplated by the intending user, who naturally enough resents any considerable increase in the price of the vehicle.

Loading and Unloading.—Assuming, however, that the difficulty of gear reduction has been overcome, the manufacturer is still liable to get himself into trouble in his efforts to please, for the purchaser—if the vehicle is for the carriage of goods—has almost certainly stipulated for ample platform area or body capacity. This can, of course, be provided, but a four-inch rise of the axles and mechanism—giving a clearance of fourteen instead of ten inches—means an eight-inch increase in the height of the wheels. Thus, if the platform or body floor has to be kept low, it must be sunk between the wheels and its width is much curtailed, while the lost space cannot be made up in length without producing an unwieldy and possibly dangerous vehicle. For this reason the platform is probably extended over the wheels at a much greater height than usual, and when the waggon reaches the purchaser the maker is blamed for supplying a vehicle which is by no means convenient for loading and unloading. A van body may be recessed over the big wheels without sacrificing a great deal of space and without raising the floor more than enough to clear the mechanism, but even in that case the centre of gravity of the loaded vehicle has been raised, and it may become top heavy and unsafe on winding and hilly roads.

Passenger vehicles of the char-à-banc or waggonette type can be provided with big wheels without these disadvantages making themselves severely felt. In the waggonette or omnibus the wheels may occupy part of the space beneath the seats, and in the char-à-banc the body usually tilts upwards towards the back to give the passengers a better outlook, and large driving-wheels are consequently no great inconvenience, while they certainly contribute enormously to comfort at fairly high speeds.

In the goods vehicle, as has been indicated, it is far more difficult to reconcile the various requirements, and it is best to compromise as far as possible. In other words, the clearance stipulated should not be in excess of that actually needed, and it is better to avoid one or two bad routes and incur additional mileage than to suffer continual inconvenience in loading, or to put up with a greatly-reduced platform area.

Good results may in some cases be obtained by stipulating for big wheels and high platform, with some mechanical means of assisting loading by the power of the engine, or with detachable bodies which can be slung into place on the platform when fully loaded.

In extreme cases, where very large and wide wheels are absolutely essential, the independent tractor is the only possible solution.

Water Supply.—Of no less importance as a feature of colonial vehicles is adequate provision for completing long journeys without taking water. A well-known expert on military transport once gave the author a South African traction driver's definition of water:—

"If you put stuff into a bucket, and if you turn the bucket over, and it falls out, it's water; if it doesn't, it's mud."

The same authority advised on watering tractions as follows:—

"Stuff of the consistency of tea or cocoa is

very welcome. Green, stagnant water is to be avoided. Most of the other colours can be passed."

In many districts the shortage of water at certain periods of the year, or the lack of an available supply convenient to the roads at suitable intervals, constitutes a serious bar against the use of steam lorries or tractors of standard types. The difficulty can be partially, but not completely, overcome by the fitting of specially large water-tanks, but these cannot at the best be of such dimensions as to remove altogether the risk of shortage. This, together with the bulkiness of coal or wood fuel, is the principal incentive to the production of the internal-combustion tractor for agricultural, general, and military purposes. Such a machine can be designed to run, say, a hundred miles under full load without replenishment of tanks.

In connection with the internal-combustion engine, water plays a minor but still an important part, and the climate of tropical countries makes it frequently necessary to introduce modifications in design, with a view to increasing the efficiency of the cooling system. Radiators, pipes, and cylinder jackets must be of very ample dimensions, and the thermo-syphon system of circulation, which is often quite adequate in temperate countries, will not suffice—at least for the heavier classes of vehicle—in very hot climates. To get high thermal efficiency, the water must not be too cool when it leaves the engine, and for this reason it would not be advisable to make standard models suitable, in this respect, for use in the tropics.

Other Modifications.—Colonial buyers may reasonably be very firm in their stipulations for high ground clearance, and for efficient cooling or adequate water-tanks, as the case may be. Other changes from standard models introduce further additions to the price of the vehicle, but may occasionally be necessary or worth the extra cost. For example, the right wheel gauge, and equal gauge of front and of back wheels, are important where roads consist mainly of tracks with two deep ruts worn by a certain class of traffic. Then, again, where sand is abundant the mechanism must be very effectively protected, and a transmission adapting itself to this is to be preferred.

Some buyers may insist upon two entirely distinct ignition systems; others may feel that a winding gear and wire rope is an essential; others, again, may want special mechanical devices to assist in rapid loading and unloading. The real utility of every such desirable feature or adjunct should be carefully considered in relation to its additional cost. From an economical standpoint it is foolish to draw up a kind of ideal specification to which no manufacturer can tender, except at an abnormal price. The spirit of compromise must enter into this, as into other matters of business, and a good deal of confidence may be placed in the fact that a really first-class manufacturer prefers ultimate success and increase of business to quick profits and final failure, and so will always endeavour to supply what will really give satisfaction.

Wheels and Tyres.—Steel wheels are more suitable than wood in tropical climates, but the latter have more "give" in them, and provide a softer drive and a certain amount of immunity from vibration. Solid rubber tyres do not wear so well in very hot countries, but in temperate climates—leaving legal restrictions out of the question—they are a positive economy, owing to the protection which they afford to the mechanism. For very light and fast vehicles even the pneumatic may be justified for the same reason.

High speeds without some resilience in tyre or wheel mean high repair bills, and there certainly seems to be a big field in tropical countries for an efficient and reliable resilient wheel. In cold climates, where snow abounds, winter wheels with composite treads should always be kept available for use on waggons or tractors which run normally on steel tyres. It is doubtful whether the solid rubber tyre can be used with economy when the load is drawn instead of carried, but its employment can be confidently recommended under anything approaching normal conditions on all self-contained vehicles carrying loads up to about six tons. Buyers who stipulate for big wheels should remember that the first cost of their rubber tyres will probably be considerably higher, but this does not imply that the tyre cost per mile will be increased. In fact, tyres of big section, or big diameter, or both, generally prove the most economical in the long run.

The Question of Fuel.—For steam vehicles the best fuel is a thoroughly good grade of steam coal, but cheaper grades of coal and also coke may be used with perfectly satisfactory results on steam waggons and tractors. In districts where coal is not available, or only obtainable at an exorbitant price, wood may be quite easily used, provided that the fire-box is specially constructed for the purpose. The author does not at present recommend the use of oil fuels on standard steam waggons and tractors. Various

systems have been worked out, but have not yet reached a point where they can be advantageously put into the hands of drivers with no great mechanical experience.

As regards the fuel for internal-combustion engines, petrol is undoubtedly the most suitable, wherever it can be obtained at a reasonable price. The cheaper and heavier grades of petrol are absolutely satisfactory, and in many countries the price of these spirits is so near to that of paraffin that there is no reason to consider the use of the latter. Benzol would undoubtedly be a real competitor of petrol if it were available in sufficient quantities, but it does not seem likely that alcohol will be of great service for a considerable time to come, experience pointing to the conclusion that it must be used only in a mixture with benzol or some other fuel, and that the more alcohol is present in the mixture the less satisfactory are the results obtained. Paraffin is very little used in Great Britain, or any other temperate countries. It is difficult to get an engine to start up from cold on paraffin, and the fuel undoubtedly soots up the cylinders rather rapidly. In tropical countries, paraffin is very successfully used without any very expensive means of adapting the engine for the purpose. There are plenty of examples of motor vans, driven by natives, using paraffin and giving very reliable service.

Section III.—Suggestions for Accelerating Trade.

Colonial and Military Transport.—Up to this point I have endeavoured to show that there is an enormous field for the development of motor traction in Greater Britain, and I have also attempted to dissipate some of those misunderstandings which I believe tend to hold back the inevitable increase of trade. It is desirable, however, that something more should be done than merely to give the trade a reasonable chance of growth, and, if possible, it would certainly be well to afford it some measure of active encouragement. With this object in view, I propose finally to outline one or two suggestions which, I think, are worthy of consideration.

Those who are substantially in agreement with me as to the nature of colonial requirements will probably also agree that, to a great extent, a compliance with these requirements would produce a vehicle eminently suited for military service in connection with transport and supply. Both in France and Germany extensive schemes are in operation, under which trials of industrial motor vehicles are held annually under Government auspices and supervision. As the result of these trials certain types are stated to be suitable for military use, and purchasers of vehicles of these types are granted very substantial subsidies, both at the time of purchase and also annually, for a certain period. In Germany £200 is allowed towards the purchase price of a vehicle of a type duly tested and approved, and this is followed by an annual payment of £50 for five years, provided that the vehicle is maintained in first-class condition. The lorries favoured in Germany are of considerable power, and carry loads of about five tons.

In France the three-tonner is specially favoured. An initial subsidy of £100 is paid on purchase, this being followed by payments of £50 per annum for three years, subject to proper maintenance. The subsidies payable on two-tonners are £80 on purchase and £40 per annum. Somewhat similar schemes have been completed, or are under consideration, by the War Offices of other countries, as, for example, Austria.

In Great Britain some attempt has been made to work on rather similar lines, but up to the present the Treasury has not sanctioned any sufficient grant to the Mechanical Transport Committee to allow of a reasonable subsidy being paid to the owners of suitable vehicles. Consequently, the annual payment is at present merely nominal, though it is augmented to a slight extent by payments for hire at a moderate rate while the vehicles are in actual service.

That the whole scheme requires revision has been proved beyond a doubt, as has also the extreme utility of motor traction in connection with the transport and supply of armies in the field. At the conclusion of the recent military manœuvres in this country, Sir John French, in his official capacity, said:—"The present system of supply and transport will soon be greatly modified by the introduction of mechanical transport on a larger scale." Then again, the military correspondent of the *Times*, after a careful study of the conduct of the manœuvres in France, wrote:—"The supply of the Third Army Corps by a service of motor lorries formed one of the most interesting features of the Picardy Manœuvres. The time has now fully come for drastic reorganisation of transport and supply between armies and their rail-heads. The French, foremost as usual with new ideas, have given us a clear indication of what we have to do."

Subsidies for Colonial Models: a Suggestion.—In view of the urgent need for the production

of a large number of vehicles suitable for military use, the question naturally arises whether the similarity between colonial and military requirements cannot be in some way utilised to assist toward the desired end. The subsidy, if it is to be attractive, must be sufficient to cover all additional expense entailed by the owner of the vehicle and to leave him with a margin of profit. If, in order to obtain the subsidy, he must purchase a vehicle which is not of a standard type, and is therefore expensive, the subsidy itself must be increased to cover the extra cost. By encouraging the demand throughout the British Empire for vehicles of suitable types, a supply of these vehicles will automatically become available at a moderate cost, and all their parts will be standardised, and spare parts readily obtainable in quantity. When this point has been reached, it is probable that many users in Great Britain itself would have no objection to employing the colonial type of vehicle, if the War Office could offer them some return in the event of their doing so. Thus a home demand might be brought into existence which would give an increased output of these types and still further decrease their cost. Finally, the subsidy which would have to be paid would not be very great, and a really suitable and adequate fleet would be at the disposal of the British War Office whenever it might be required for operations in or near this country. Such a fleet would also, if necessity arose, be capable of being effectively used in almost all parts of the globe, and even in countries in which the road system is by no means fully developed.

It seems, however, that it would certainly be extremely useful if a nucleus of a suitable fleet were available locally in each of our more important colonies. There is at present a strong tendency throughout Greater Britain towards some form of national service, and colonial Governments are willing and even anxious to assist in the defence of the Empire as a whole. Would it not then be a wise action on the part of these Governments if they were to consider offering a reasonable subsidy to encourage the use of suitable motor vehicles in their territories, these vehicles being available for manœuvres, and also in case of war? The cost of carrying out such a scheme on a sufficient scale would not be at all high, and the result would be not only the production of a mechanical transport column for military purposes, but it would also constitute a powerful incentive to the general development of mechanical transport, and consequently would tend towards the material improvement of the internal communications of those colonies the Governments of which saw fit to adopt a subsidy scheme. The matter is one for the discussion of which the next few months will offer unrivalled opportunities.

If this suggestion be deemed worthy of consideration, I think it will be found that there are not many real difficulties in the way. The subsidy would, of course, only be granted to vehicles obtainable from the British market, or manufactured in the colonies themselves. Periodical organised trials might be held in Great Britain if it seemed desirable, but in all probability this course would not be necessary, as certificates could be granted to makers in respect of certain suitable types after individual trial and inspection by a committee, which might with advantage be composed partly of military and partly of civil experts. If it were understood that the vehicles of types subsidised by colonial Governments would be given first claim to subsidy by the British War Office itself, there would be a powerful inducement to manufacturers to turn their attention to the production of suitable types in sufficient quantities to ensure distribution at reasonable prices, and adequate standardisation and interchangeability of parts.

As things are at present, it cannot be expected that a user in Great Britain would, for example, go to the expense of fitting extra tanks, or incur the inconvenience following upon an exceptionally high ground clearance, unless he could see some definite advantage following naturally upon the expenditure or trouble. Consequently the colonial demand stands alone, and, so long as it is insufficient to provide for considerable outputs by manufacturers, the price of special vehicles must necessarily remain rather high, and the number of machines really suitable for military use must continue to be comparatively small.

It seems to me that, by adopting the suggestion outlined above, colonial Governments might afford real assistance towards the defence of the Empire, while at the same time benefiting both in the matter of their own local defence and also in the general development of their trade and territory. These possibilities should not be forgotten by Government officials when questions arise as to the establishment of light railways, tramways, or road motor services. The last-named are adequate for moderate traffic, and when they have been the cause of extending that traffic to sufficient dimensions, light

railways can be constructed and the road vehicles can be transferred to other less developed districts. By this process the roads grow almost automatically, and an essential element of progress is thus assured, while the colonial Government is continually in possession of the valuable asset of military transport, not limited in its use—as is a railway or tramway—to the specific district in which it chances to be usually located.

A "Coronation Review."—In conclusion, I should like to put forward one more suggestion which may, perhaps, be considered trivial, but which at the same time is another means towards the desired end. In view of coming events, London will, in the course of the next few months, see an influx of an enormous number of very influential legislators and business men from every territory in the British Empire. Many of these visitors, while business may not be the first object of their stay in this country, will not neglect any real opportunity of learning more of any means which may be offered to assist in the development of Greater Britain. Consequently it would, I think, be well worth while to organise a review of a representative collection of industrial motor vehicles from the British market, and to arrange for this review to take place on a day during, or as near as possible to, the week of the Coronation. An event of this kind would be most effective if it were judiciously limited both as to time and also as to extent. I do not for a moment suggest that a heterogeneous collection of all sorts and conditions of motor vehicles should be gathered together from every available quarter. The fact that mechanical traction is used in all trades will be obvious enough to visitors who keep their eyes open in the London streets. What would, I think, appeal to them far more would be a carefully-organised exhibit in which all the leading types were represented in strictly moderate numbers, special prominence being given to designs which appear to be, or have already shown themselves to be, suitable for use in countries where the road systems are not as yet fully developed. The review would not be limited in its interest to the mechanism of the vehicles, as by careful organisation it would be possible to ensure that the coachwork, the wheels and tyres, and even the fittings and accessories, were representative of a wide range of utility, and of the latest improvements and refinements. It would be possible, in a gathering of not more than forty or fifty vehicles, to show very clearly and concisely what the British market has to offer Greater Britain as an aid to the improvement of internal communications. An hour or so spent even in a merely casual inspection of the vehicles reviewed would leave a lasting impression of the ability of this young industry in Great Britain alone to meet all the requirements of the British Empire, and would help to counteract any false impressions which may exist, and any tendency to neglect the Mother Country in favour of others which, in point of fact, have not reached anything approaching the same point in the development of the utility motor vehicle. I have little doubt that, given the support of the leading firms in the manufacturing trade, it would be possible to get together a committee of very great influence, which would ensure that proper publicity should be given to the whole scheme, and that very many of the more prominent visitors to London should avail themselves of the opportunity of inspection offered. The author has already taken steps privately to obtain opinions as to this proposal, and up to the present his suggestions have, on the whole, been very favourably received.

Until the horse has been ousted from the streets altogether, a really adequate impression of the tremendous progress made by motor traction will not be obtainable in a convenient and impressive form, except by some such demonstration as that suggested, and it would, I think, be most unfortunate if we were to allow all these visitors from our colonies—men whose influence will be widely felt in their own territories—to leave this country without being shown that, in the all-important matter of road transport, Great Britain is fully prepared to meet their needs. This proposal for what might be called a Coronation review of industrial motor vehicles has already made some real steps towards fulfilment, and the author would welcome suggestions and support from those who are able and willing to help in the furtherance of the scheme.

In concluding what I fear has been an unduly lengthy paper, the only apology I can offer for so far taxing the patience of my audience is that I have attempted to touch upon a subject the importance of which I feel very deeply. It is impossible to overrate the value of facilities for communication. They are at the bottom of the whole fabric of civilisation, and constitute a power which, if it is properly applied, can help in no small measure to consolidate the British Empire, to strengthen its defences, and to augment its trade.

APPENDIX.

NOTES ON TRADE OPENINGS IN GREATER BRITAIN.

ASIA.

The Indian Empire.—The principal factors operating against the development of mechanical transport in India are officialdom and native lack of enterprise. As regards the first, it is frequently difficult to further any new project without abnormal delay and complicated correspondence. The other difficulty is due to the fact that the natives do not set much value on time, and are quite satisfied with the speed of their primitive forms of transport, which can be operated at a very low cost. There is also a disinclination to subscribe capital for progressive ventures, and foreign capital consequently has to be employed in most cases where schemes of any size are contemplated.

From a series of reports prepared by executive engineers and other qualified residents, and subsequently transmitted to the Colonial Office, it appears that motor traction would be beneficial to a great part of India. Generally speaking, one gathers that the districts where a demand is most likely to spring up are those within a radius of some 400 miles of Bombay. At the same time numerous favourable reports are received from districts in the Punjab, the United Provinces, the Southern portions of Madras, and the neighbourhood of Calcutta. Up to the present, development has been arrested by the failure of early experiments, which were frequently made with unsuitable second-hand vehicles quite unfit for the work, or else with touring cars carrying excessive loads of goods or passengers. There has been a recovery during the last year or so, and prospects of development have improved.

If it were possible, one of the best ways of developing motor transport in India would be through the medium of the railway companies. There are many districts where traffic is insufficient to justify a branch line, and where a motor service would yield a good return independent of any benefit to the railway itself. The whole scheme might with advantage be developed in conjunction with military transport. In addition to road vehicles, the railways would probably find it advantageous to adopt rail motors for light traffic and also for inspection work. In the towns, motor traction might well be used for the cartage of refuse and for the watering of streets. In some districts passenger motor services might be made to pay if catering for European traffic. The rates at which natives travel are so low that ordinary passenger vehicles would not pay if run for their benefit. The only possibility in this direction appears to be the use of tractors, drawing one or two trailers with ample seating accommodation. These would not give a high speed, but from the natives' point of view the defect is of little consequence. Touring cars might be extensively adopted by Government officials as a means of saving travelling expenses and economising time on cross-country routes.

As regards fuel, the price of coal varies very much in different districts. It is extremely cheap near the mines, but may be very expensive in more or less inaccessible districts. The quality of the coal is also variable. Water is usually abundant, so that there is no bar to the use of steam vehicles. Both petrol and paraffin are available, the price of the latter being distinctly low. Internal-combustion vehicles should have large radiators and adequate cooling systems on account of the hot season.

On the subject of the possibility of the general use of motor traction in India, Captain E. N. Manley, R.E., in a report on "Mechanical Road Transport for India," published by the Royal Engineers' Institute, wrote:—"As regards climbing steep roads, the modern motor vehicle can go wherever a horse or bullock-drawn cart can work . . . For haulage of loads not requiring a greater speed than five miles per hour, the cheapest form of motor is the steam lorry, tractor, or traction engine . . . Many traffic routes, such as are worked by the railways as out-agencies with bullock-cart services, should be workable by mechanical means."

Calcutta.—Turning to specific districts, the development of mechanical traction in the neighbourhood of Calcutta has not, up to the present, been rapid. The Calcutta Port Commissioners use petrol vans, and the East Indian Railway have several steam and petrol vehicles. Various mills have also been experimenting. A motor omnibus service was tried in Calcutta, but without success, and it is too early at present to predict the future of the taxicab movement in that city. Up country there are a certain number of internal-combustion lorries and passenger vehicles generally giving satisfaction, and there is little doubt that a considerable demand for fairly light vehicles of this class is bound to arise sooner or later, both for passenger work and also for the carriage of goods.

Bombay.—As the whole district around Bombay appears to be suitable for mechanical transport it may be worth while to deal at some length with this centre. As elsewhere, early attempts were made to utilise pleasure cars for commercial purposes, and unsuitable vehicles were tried for omnibus services, and subsequently for goods work. The repeated failures of these vehicles, which changed hands from time to time, gave the impression of a large number of unsuccessful machines, where, as a matter of fact, only a few existed. Many of the cars were second-hand when they reached Bombay. During

the last two years steady progress has been made. Both the railways serving Bombay use parcel delivery vans, and a service of petrol electric omnibuses has recently been started in the Poona district. Petrol lorries are also used to a certain extent by private concerns. Up to the present the principal difficulty has been the maintenance of tyres. The cab services of the Indian Taxicab Co., and of Messrs. Hill, Sawyer and Co., are well patronised, but nothing definite can be said yet as to their ultimate financial success. Steam lorries and tractors are finding increased favour for the transport of goods. In Bombay itself there are now about a dozen steam lorries of various makes in service. The municipality and others employ steam tractors. There are also one or two traction trains, but it is stated that there are complaints against the noise and vibration of the heavier machines. There is undeniably a good opening both for passenger and for goods services. The light railways cannot cover the ground completely, and many of the towns are more suitable for road vehicles than for electric tramways. For passenger purposes, bodies of the single-deck omnibus type with accommodation for as many passengers as possible, and with divisions into classes, would probably prove most suitable. The price of commercial petrol is so near that of the better grades of kerosene that it does not seem necessary to attempt to use any but the former as fuel. Petrol was recently quoted at 12 annas to 1 rupee per gallon in various parts of the Presidency; high-grade paraffin at about the same price. In Bombay itself commercial petrol costs 10 annas, and the ordinary kerosene 8 annas per gallon.

For goods services, steam vehicles seem to be very suitable. The price of coal varies in the Presidency from 12 to 20 rupees per ton. Wood costs from 5 to 10 rupees, according to quality. Near the mines coal can be obtained at a ridiculously low price. There is plenty of water, except in a few very mountainous districts. The town roads are in good condition, but the district roads, though metalled, are not very suitable for heavy traffic. The principal difficulty is in the existence of bridges and culverts, which are only safe for quite light roads. When existing bridges are strengthened, most of the roads will be suitable for all kinds of motor traffic, at least in the dry season. Gradients are easy in the northern parts of the Presidency, but steep in the southern parts, where the roads, however, are harder and better. As regards local requirements, engine power should be ample, as also should be ground clearance. Wide tyres are advisable on steel-tyred vehicles. Native drivers of steam or petrol vehicles can be obtained at 50 to 80 rupees per month, but these men would not generally be capable of undertaking serious repairs. At present there are no adequate repair shops except in Bombay City, and even there the charges are, as a rule, very high. This difficulty will decrease automatically as the number of vehicles in service goes up. It is stated that at present local capitalists are shy of motor transport schemes, while Government favours light railway and tramway projects.

Ceylon.—It appears that road and other conditions make Ceylon very suitable for mechanical transport, but that the attitude of the Government has up to the present retarded development to no slight extent. The Government has contemplated starting services itself, but this intention appears to have been almost abandoned. Meanwhile, private enterprise is not given a free hand. A suggestion has been made that the money which was to have been devoted by Government to the purchase of vehicles should go to the improvement of the roads, and that a charge should be levied for every ton of produce carried by motor traction over the roads where the improvements have been made. It also seems that the Government may retain control over the rates charged for goods and luggage. As there appears to be an admirable field for motor traction in the island, it is to be hoped that all obstacles to development will be removed in the near future.

The Federated Malay States.—The Federated Malay States Railway owns a large fleet of motor vehicles mainly used for the carriage of passengers. The fleet appears to be, at present, in excess of the requirements of the services, and consequently only a comparatively small percentage of the vehicles are kept regularly running. In spite of this, the services would show a profit if it were not that an enormous allowance is made for depreciation. With reasonable allowance under this head the venture would certainly be a financial success, considered independently, and without allowing for the beneficial effect which it must have upon the railway passenger service.

There are also a number of private companies running passenger vehicles, principally used by coolies. These vehicles number perhaps twenty or thirty. There is an opening for a few taxicabs in the larger towns. At present ordinary touring cars are used for hire purposes. European engineering firms and also mineral water manufacturers already use motor lorries and vans. Petrol is produced in Sumatra, and costs about 1*s.* 6*d.* per gallon when purchased in large quantities. Paraffin is cheap and obtainable anywhere. Coal is dear and mostly imported; wood is obtainable anywhere. An engine using paraffin as fuel would be very suitable in the Malay States, but there is no difficulty about operating steam lorries, etc., provided they use wood fuel, as water is plentiful.

The roads are good, but somewhat narrow. The country in the interior is mountainous, but the gradients are not severe, being generally about one in thirty for long stretches. The

corners are very sharp. Standard English cars are used in the Federated Malay States, and there do not appear to be any special local requirements in the matter of design. Native drivers are available at £3 to £5 a month. There is at present a scarcity of good mechanics for repair work, but garages are gradually being started under European supervision. Charges for repairs should be reckoned as somewhat higher than in England.

In comparison with many Continental countries, including France and Austria, the Federated Malay States are ranging well to the front in matters relating to mechanical traction, although bullock haulage is very cheap.

Aden.—The territory of Aden offers a very limited field for motor traction. There is a service of single-decked passenger vehicles in use on what is probably the only possible route. Owing to the great heat, the upkeep of wheels and tyres is an expensive matter. Drivers and mechanics have to be brought from Bombay. There is no water except that which is condensed, and sold at about 3*s*. per 100 gallons.

AFRICA.

The requirements of British possessions in Africa cannot be dealt with in the lump, owing to the difference of conditions in the various colonies. Generally speaking, on the West Coast of Africa, and also in Uganda and British East Africa, there are a very limited number of roads, but where roads exist at all they are of reasonably good quality. The opening for motor services is almost entirely for the carriage of produce from the interior to the coast or to rivers. In Southern Nigeria there is a motor service operated on a considerable scale by the Government. No difficulty is found in using paraffin fuel, which can be obtained at something under 1*s*. per gallon, while petrol is extremely expensive. This use of paraffin is particularly interesting, as the vans are all handled by natives, who are not only cheaper than Europeans, but are able to stand a reasonable day's work, whereas European drivers are very rapidly tired out by the climate. Throughout the East and West African colonies there are many districts which do not justify the construction of railways, where motor services are now operated, and will doubtless be used to a much greater extent than at present. These services are responsible for the mails as well as for the carriage of goods. In East Africa there is also a demand for a really good internal combustion tractor for general agricultural and haulage work. Here, as in many other parts of Africa, cultivators are very dependent upon their beasts, and any epidemic among the animals is consequently liable to prove very ruinous. A great part of South Africa has similar requirements in the matter of agricultural motors, and many of the less developed districts are not sufficiently advanced to encourage motor traction in any other form at present. This does not apply to the principal towns in United South Africa, where the usual developments may be expected. Probably the best centre from which to distribute through British South Africa generally, and which would also be reasonably convenient in view of the probable extensive demand for improved road transport from the mining districts, would be either Johannesburg or Pretoria. Consequently some detailed particulars are given as to the local conditions prevailing in these two towns.

Johannesburg.—In Johannesburg itself the South African Railways use steam waggons extensively for the haulage of general merchandise, and several cartage contractors own similar vehicles. Many of these waggons are used principally for hauling instead of carrying, taking very heavy loads on two trailers with excellent results. Motor cabs are used to a considerable extent in Johannesburg, about seventy-five being licensed. They are, in fact, rapidly taking their place in all the principal towns of South Africa. There appears to be a very good opening for all classes of trade vehicles, and there are numerous inquiries for agricultural motors, a certain number of which have reached the district lately.

Some correspondents recommend paraffin as the most suitable fuel, as coal and wood are stated to be scarce and dear in many parts. Paraffin costs 12*s*. 6*d*. or 13*s*. per case of eight imperial gallons. In Johannesburg itself coal is obtainable at about £1 per ton, but in outlying districts it is very much dearer. In the neighbourhood of the town itself there is plenty of water, but in some districts it is very scarce during the summer. There is, however, generally enough to make the use of steam vehicles possible. The roads round the principal towns are generally good. The roads in the veldt are merely bullock-waggon tracks across country which is sandy in places and clay elsewhere. In some districts the tracks are very level, but in places gradients up to one in five are encountered.

As regards local requirements, there should be ample margin of power to negotiate bad places. The ground clearance should be as high as possible, eighteen inches being advised for the outside districts. The steering lock should be ample, and chain steerage is recommended for the steam waggons and tractors. For the heavier classes of vehicle, metal tyres are generally the most suitable, and solid rubber for express work.

As regards labour, there is plenty of raw material, and a sufficiency of skilled drivers is to be had round the towns. There are plenty of repairing shops in the towns, but drivers are generally expected to do their own repairs. In the country districts repair shops are very scarce. The wages of trained drivers are somewhat high.

Touring cars are well represented in the district, but representatives capable of pushing the sale of industrial vehicles are very scarce. Actual demonstration on the spot will have more effect on the development of the industry than any other method.

Pretoria.—It is stated that there is a great future in the neighbourhood of Pretoria for lorries carrying about two tons, and it is suggested that road trains of suitable design would also be successful. Prejudices exist against traction engines, which might also operate against steam tractors, but steam lorries would do well, provided that their boilers are adapted to use water of bad quality. The roads are good in the town, but indifferent in the suburbs and very bad outside. In some places there are patches of black turf which, after rain, sticks to the wheels, completely clogging them. Even the ox waggons sink up to the axles in these places and have to be dug out. These conditions only prevail between the months of November and March. There are also patches of sand often six inches deep, the sand being very loose and shifting. The road clearance should be as great as possible, fifteen inches being none too much on account of boulders in the roads. Also rivers two feet deep may have to be crossed. Round Pretoria the roads are fairly level, but on account of the dongas (dry rivers) occasionally encountered, all vehicles should if possible be fitted with rope-winding gears. Large radiators are advisable, and these should be amply protected, as native drivers of horse traffic are very careless and collisions are not infrequent. Ignition should be by magneto, and might be duplicated. Paraffin costs about the same as in Johannesburg, but petrol is about 50 per cent. more expensive. Arrangements should be made for extra air supply to carburetters, owing to the high level of the land, both Pretoria and Johannesburg being over 4,000 feet above sea level. Steel wheels should be fitted, and, owing to the difficult pieces of ground encountered, a very low first speed and reverse are recommended.

AMERICA.

Canada.—Leaving on one side the enormous potential demand for agricultural implements throughout a wide area of Canada, the most promising fields for motor traction vehicles of various classes lie on the one side in the Provinces of Quebec and Ontario, and on the other in British Columbia. There is already a big demand, which will increase still further, in the Canadian cities on and near the St. Lawrence, and the greatest obstacle to British trade in this district is likely to be the severe competition of American products, which, though not of the same quality, are obtainable at a low price. Both here and in the neighbourhood of Vancouver a limited number of British manufacturers have cultivated trade with admirable results, and their example might well be followed by others, prompt action being necessary if this very valuable territory is to be available for the output of British trade.

Ottawa.—As examples of which some particulars may be given, we may take Ottawa and Vancouver as typical of the leading Canadian towns. The possibilities of trade in Ottawa are very great. There is room for a quantity of taxicabs, a number of large omnibuses or chars-à-bancs for sight-seeing purposes, and also for smaller omnibuses running country services, and combining the duties of a passenger carrier with those of a Royal mail. Services of this sort can operate from city to city, and the same applies to vehicles for the carriage of light merchandise. There is also a demand for vans or lorries, from one to five tons, for use by traders of all sorts, and the general demand, already big, is rapidly increasing.

The price of petrol varies from 15 to 20 cents per gallon, and this fuel is almost exclusively used, though there appears to be nothing to prevent steam tractors and lorries from being also employed with advantage. In the Province of Ontario the roads are mainly macadam, the remainder being gravel, and the surface is on the whole fairly good. In the Province of Quebec the chances of development are not so good, as there are fewer roads, and these of a lower quality, making them unfit for heavy traction except in the height of summer. There is, however, a strong movement in favour of better roads, and the next few years will doubtless see great improvements.

As regards special requirements, ground clearance should be not less than twelve inches, and wheel-gauge should preferably be the standard 4 feet 8½ inches. Drivers and mechanics are available, but wages are high, and there are good openings for responsible and sober men from Great Britain. Drivers get from 12 to 25 dollars per week and repair men from 20 to 25 cents per hour. Good mechanics get as much as 30 to 35 cents per hour. Generally speaking, British manufacturers, with the assistance of the preferential duty, should be able to hold the field for the higher classes of mechanically-propelled vehicle.

Vancouver.—In British Columbia the demand is principally in the district of Vancouver and Victoria. In the neighbourhood of the latter there are steep gradients and rough roads, and many of the bridges will not carry more than about three tons. The principal haulage is lumber and cord wood.

Quite a number of industrial motor vehicles are in use in Vancouver, and their employment is increasing rapidly. These vehicles are of all kinds for light and heavy loads, and are used by retail and wholesale firms, and also by the city scavenging and fire departments. Those of the best makes have proved very economical.

Vancouver is stated to have more motor cars in proportion to the population than any other city. These include chars-à-bancs, hotel omnibuses, taxicabs, lorries, and vans of all kinds. Petrol-driven vehicles are principally employed, but water would be available for steamers. The roads are not good at present, but are being gradually improved, and gradients are not exceptional.

As regards local requirements, a good clearance is favoured, but is not absolutely essential. A low-built waggon for heavy work is in demand. This would have the floor of the body brought down very low to avoid lifting of heavy goods. Efficient labour is available for driving and repairs.

The trade in British vehicles is greatly affected by the cheapness of some of those supplied from the United States. Consequently first cost is an important consideration.

WEST INDIES.

There are several good openings for mechanical transport in the West Indies. Without attempting to deal separately and completely with every British possession in that part of the world, it may be said that motor traction is already finding a footing in British Guiana, Jamaica, Trinidad, and Barbados, and the near future should show good trade in these quarters, and possibly also in other islands.

Jamaica.—In Jamaica the country is of a mountainous character, but many of the roads are quite good and are excellently maintained. Internal-combustion engined vehicles appear to be most suitable, as kerosene is obtainable anywhere, but coal is comparatively scarce. For general purposes, vehicles of about two tons would meet requirements, as these would not be too heavy for the roads. Sufficient power would be required to negotiate severe gradients, but excessive power would be undesirable if the vehicles are to be handled by native drivers, unless the maximum speed is very definitely limited. Natives who will train into good drivers should be obtainable for about 4*s*. per day. On many roads there are rivers to be forded, but if these are impassable it is generally possible to complete the journey by a detour, as the rivers are bridged. In Kingston there should be a good opening for vans carrying about one ton, for the use of tradesmen generally, and cold storage vehicles should be useful in several trades.

Trinidad.—There are a certain number of British-built lorries and vans in service in Trinidad, and results up to the present have been satisfactory. There are good openings for omnibuses, lorries, and private vehicles. Petrol is obtainable at 1*s*. 7*d*. per gallon, paraffin at 1*s*. 3*d*., coal at 30*s*. per ton, and wood at 10*s*. per cord. There is a sufficient general supply of water for steam vehicles. Roads are macadamised and of good surface. Gradients are only moderate, nothing much worse than one in ten being met. Ground clearance should be high, and solid rubber tyres of large section should be fitted. Native labour is available at prices varying from £1 to 75*s*. per week, but trained drivers are not obtainable on the spot. There are in all between fifty and sixty mechanically-propelled vehicles in the island.

British Guiana.—In British Guiana the roads are good, but there are some short sharp gradients and numerous abrupt turns over bridges. Generally speaking, the country is flat. There are no rivers to be forded, and the rates obtainable for the carriage of goods from the plantations are quite high enough to allow a margin of profit if motor vehicles are used. The quality of the water along the roadside is not very suitable for steam vehicles, but suitable water is available at sufficient intervals, and coal is also obtainable.

Bermuda.—An interesting example of the possibilities of road transport is to be found in Bermuda, but the name of this colony has not been mentioned as a likely field for motor traction, owing to the existence of prohibitive legislation against motor cars. At the moment of writing it is not certain how the rapidly-increasing tourist traffic in the colony will be dealt with, as rival proposals involving the use of either electric trams or motor vehicles have recently been under consideration. It is quite possible that a long monopoly may be granted to a tramway company, in which case the prohibition against road motors will probably continue in operation.

AUSTRALASIA.

There is a certain similarity in the demand for mechanical transport throughout Australia and New Zealand, though the latter is in general far more hilly. In the large cities, requirements do not of course differ very much from those of Great Britain itself, with the exception that a very adequate water-circulation system is necessary, owing to the climate, and that vehicles running out on to country roads require a high clearance. In all the big cities there is an increasing demand for taxicabs, and these are to be found in considerable numbers. For example, in July last there were forty-three motor cabs licensed in Sydney, and notice of registration of a further twenty-five had been given. The great majority of these cabs are of British make. The principal towns are taking up motor fire appliances and municipal motors very readily, and with good results. In many country districts there is a big demand for a suitable type of agricultural motor, and, generally speaking, for a tractor capable of negotiating unmade roads. There is also a big field for motor mail services in very many districts.

Naturally the principal towns form the chief centres from which the employment of motor

transport is likely to spread. Consequently, the following notes refer to the conditions in districts around some of the most important centres.

New South Wales: Sydney.—Motor vehicles are already extensively employed in Sydney for business purposes. The most popular type of vehicle at present appears to be the light petrol waggon for delivery purposes, designed to carry from 15 cwt. to two tons. The passenger-carrying vehicle is, comparatively speaking, a negligible quantity. Motor vans and lorries are already used in almost every conceivable trade. It is stated, however, that Sydney is behind Melbourne in the development of the new method of transport. If this be so, the topographical conditions may have something to do with the facts, Melbourne being built on flat land undivided by any expanse of water incapable of being bridged, whereas Sydney is replete with hills and inlets. Many streets are narrow and rough of surface. They are paved with hard wood blocks except on the most severe gradients. The most popular fuel is petrol, which costs about 1*s.* 4*d.* per gallon wholesale. Steam lorries have been used to some extent, but appear to be giving place to internal-combustion vehicles. Water is generally of poor quality.

Special requirements are not remarkable. Adequate clearance is, of course, necessary, and the same applies to the steering lock. Tyres should be of wide section. Bodies of all vehicles are generally built locally. Chain-driven vehicles should have their chains encased on account of sandy roads. Carburetters built for use in Great Britain are frequently incapable of taking as much air as is required in some districts in Australia. A reliable correspondent lays great stress on this point as deserving of the attention of makers. As regards drivers, labour is available in ample quantities, at 30 to 50 per cent. above English rates. Repairs are at present expensive. There are good openings for reliable driver-mechanics.

Queensland: Brisbane.—Mechanical transport has not yet developed as far in Brisbane as in Sydney, but, generally speaking, requirements are fairly similar, and during the last eighteen months cars have been imported at an increasing rate, and these appear to give general satisfaction. Only recently, the first "penny section" motor omnibus service to run in Australia was started in Brisbane by Mr. C. A. Wood. On the whole, motor omnibuses have not found favour to the same extent as goods-carrying vehicles.

Victoria: Melbourne.—The most popular type of motor vehicle in Melbourne at present is the 15 to 25 cwt. van or lorry for quick suburban delivery of goods. The large warehouses have been the principal buyers, and a certain number of two-ton and three-ton vehicles have also been put into service. Unless an enactment has been passed within the last month or so, Melbourne has as yet no licensed taxicabs, vehicles of this type being hired by arrangement from the garages. Generally speaking, there is a fairly good opening in Victoria for industrial motors, though horses are cheap, and it is consequently difficult to introduce a new method of transport. There are a certain number of motor tractors in use in agricultural districts, but this development has not yet expanded fully.

All fuels for petrol or steam vehicles are available. Petrol costs about 1*s.* 4½*d.* per gallon wholesale, kerosene about 10½*d.*, and coal about 24*s.* per ton. The use of steam vehicles is, however, restricted, owing to the scarcity of water in some parts of the country. The roads are chiefly macadam, but are rough and uneven on the surface, and there is generally a good deal of loose metal lying about. Gradients are not severe. As regards design, the usual colonial requirements hold good. At present it is somewhat difficult to obtain locally replacements of some of the best makes of rubber tyres. Labour is scarce and dear, and drivers have to be trained. The labour market is not at present in a satisfactory condition, but there are a fair number of concerns capable of dealing adequately with repair work.

South Australia: Adelaide.—Motor traction is not yet extensively employed in South Australia, but motor lorries of from one to five tons' capacity are just beginning to find favour. There are now about twenty in and around Adelaide, in the service of carrying companies, market gardeners, and merchants. About five lorries are fitted with seating accommodation and are used for picnic parties and passenger traffic. The Electric Light Company uses a six-ton petrol lorry for carrying coal. Reports generally are very favourable, and there is likelihood of a good deal of business being done in the near future. Most of the lorries in use have as yet been run less than twelve months. A Renard road train and a twenty-ton traction engine are in use in adjacent mining districts.

There is undoubtedly a big future for the motor tractor and motor lorry, as the country is very extensive and is not well served by railways. Agricultural motors are not yet used to any great extent, but a good machine of this type, easily manipulated and capable of ploughing about thirty acres a day, would find a ready market. The immediate demand will be, however, principally for lorries of from one to five tons.

Petrol costs about 1*s.* 4½*d.* per gallon. Paraffin is not at present used as fuel for motor vehicles in the district. Water is scarce in many parts, and steam vehicles are handicapped accordingly. Macadamised roads are, as a rule, only of moderate quality. Adelaide itself is on a plain with very few gradients. To the south and east there are hills with gradients of one in eight or nine, and occasionally one in five. In South Australia generally there are all sorts and

conditions of roads, many unmade, and situated in sandy and hilly country.

The principal local requirement is ample ground clearance, which should not be less than twelve inches in order to escape stumps, stones, and boulders. The wheel gauge should preferably be the same as that of farmers' waggons, say, from sixty to seventy inches. A good steering lock is an advantage in some cases. Rubber tyres are best for city use, and on the macadamised roads, but for agricultural or country work steel tyres with cross-bars should be fitted. Springs and axles should be strong. The bodies of the vehicles are nearly all made locally.

The average Australian, being very intellectual and resourceful, readily masters details of mechanism and makes a good driver. There are some well-equipped shops where repairs can be effected equal to the best British work, but at a higher cost owing to the rate of wages and cost of raw materials. A first-class motor mechanic will get 11*s*. a day of eight hours.

Any firm wishing to get hold of the trade in this district should send out a really good man to study the requirements on the spot.

Western Australia: Perth.—The roads for a radius of about twenty-five to thirty miles around Perth are suitable for fairly heavy motor work, the principal route being to Fremantle and to Midland Junction. There is here an opening for a parcels delivery service. Roads are somewhat sandy, but gradients are not severe. Between Fremantle and Perth there is a good route for a parcel and heavy goods service. The cartage of goods from Fremantle either by rail or by barge to Perth is accompanied by a good deal of tedious and annoying formality, and goods are not infrequently damaged on the way. Five-ton petrol lorries could operate the service for the heavier goods. A low fourth-speed may be useful for emergencies, and the water-circulating system should be thoroughly effective. For parcels delivery two-tonners would be suitable. Coal is dear, and water is scarce in places; consequently steam vehicles are at a great disadvantage. There is an opening for a passenger service between Perth and Guildford, a distance of about seven miles. There should also be room for a few motor chars-à-bancs for pleasure trips from Perth, especially to Mundaring Weir. Business houses in Perth could advantageously adopt vans carrying one to two tons. Early experiments in motor traction failed owing to incompetent management or faulty selection of vehicles.

Solid rubber tyres must be detachable without a press, road clearance must be ample, and large diameter road wheels would be an advantage. With the features mentioned, and with a very low fourth speed, the requirements of most reasonable districts in Western Australia should be well met. There is also an opening for a good agricultural petrol motor with the right type of wheel for sandy country.

New Zealand: North Island.—In Auckland there is an opening for a certain number of trade vans and also for a few cabs. A motor omnibus service has been tried, but was not well operated and was discontinued. It seems, however, as if there might be an opening in this direction. In the immediate neighbourhood there is not a very large field for agricultural or general-purpose tractors, but in the Waikato district there is stated to be a potential demand for an enormous number of engines of this type. These should preferably be fitted with internal-combustion engines, as petrol and paraffin are obtained at moderate rates, but coal and wood are both expensive, and water, though found in considerable quantities, is not always convenient to the roads. The road surface in the town is fair, but outside poor. The gradients, on the other hand, are heavy in Auckland itself, but very moderate in the country round about. In this district, as in the others mentioned above, special requirements are not exceptional. Moderately high engine power is needed, together with a reasonable ground clearance.

As regards labour, there is plenty of raw material available for drivers. Rates are, however, high, being from £2 15*s*. to £3 per week, with an eight-hour day. There is a scarcity of mechanics properly qualified by training to deal with the repairs of motor vehicles.

Going further south, Wellington is not very dissimilar in requirements from Auckland. Motor cabs are likely to be extensively used, and there is an opening for light vans for delivery work in the immediate vicinity of the town. Tram services work wherever the streets allow them to be safely operated, so there is probably no opening for motor omnibuses. The nature of the country round about is such as to restrict the use of the heavier type of lorry and tractor. The roads outside the town are bad; those inside are of good quality, but very frequently heavy gradients are found. The streets being in many places narrow, a sharp steering lock is advisable, and some form of non-skid tyre is to be recommended on the clay roads in the district, which get very greasy at times.

New Zealand: South Island.—Christchurch probably offers as good a field for the development of mechanical transport as any town or district in New Zealand. There is a good opening for vans, lorries, and cabs, and also for motor omnibuses feeding the tram systems and operating in less thickly populated districts. There will also be a big demand for agricultural motors and general-purpose tractors. These should preferably be fitted with internal-combustion engines, since, though all fuels are available at reasonable prices, water has to be obtained from artesian wells, and the supply cannot be depended upon in the country districts. The roads all about are

of good quality, and gradients are negligible. Conditions of labour are similar to those at Auckland.

In Dunedin there are again limited openings for vans and cabs. There is a very big field for agricultural tractors in Southland and along the east coast of the South Island. Either steam or petrol engines can be conveniently employed, as the cost of fuel is reasonable, and there is a sufficiency of water. The roads about Dunedin are of good quality, but newly formed, and consequently rather soft and heavy.

There are a few steam vehicles in use. Coke and good coal are obtainable at about 25*s*. a ton, and lignite at 9*s*. to 15*s*. a ton.

Powerful engines and wide tyres are desirable, and high clearance is essential. Weights should not be excessive. A complete set of spare parts should accompany every vehicle sent out. Pumps should be made with a good margin, as consumption of coal and water is high.

[NOTE.—For the information contained in the Appendix the writer is indebted to the following, and to a large number of other correspondents, who have taken considerable pains to give him the benefit of their intimate knowledge of local conditions :—

Mr. L. M. Dave, B.A., Managing Director of the Gujarat Automobile Transport Co., Bombay; Mr. J. H. M. Robson, Federated Malay States.

Messrs. Smith Bros. & Co., Users and Agents of Motor Vehicles, Port of Spain, Trinidad, B.W.I.; Messrs. MacDonald & Co., Concessionaires for "Albion" Cars, 80, Queen Street, Ottawa, Ontario; Messrs. Walter Hayes & Co., Vancouver, British Columbia.

Mr. Richard Ruben, Importer, Johannesburg; Mr. C. E. S. King, Cartage Superintendent, South African Railways.

Mr. G. Hamilton Grapes, A.I.A.E., Consulting Engineer, 160, Lambton Quay, Wellington, New Zealand; Mr. G. Canton, formerly of New Zealand; Mr. T. D. Chapman, Agent, Kenneth-street, Longueville, N.S.W.; Mr. Herbert Filmer, Editor of "The Motor in Australia," Sydney, N.S.W.; The Tarrant Motor Co., Melbourne, Victoria; Messrs. Duncan & Fraser, Motor Agents, 46, Franklin-street, Adelaide, South Australia; Mr. A. Adams, Perth Motor House, Hay-street, Perth, Western Australia.]

DISCUSSION.

The CHAIRMAN, in opening the discussion, said the audience had listened to a most interesting and comprehensive paper. It touched on a great many subjects; it foreshadowed what might take place in the motor trade, and he thought that the author was not very far wrong in his prognostications. In bygone days, when the railways were first being made, it was prophesied that they would be failures, because the wealthier classes would keep to the road in the old stage coach, but those prognostications were absolutely wrong. Now, the roads were being used again, and motors were carrying a very considerable number of passengers, as well as goods, which were previously carried by the railways. He did not think the motor trade on the road had in any way reached a climax; on the contrary it would very considerably increase. In the colonies the motor trade at the present moment was in its infancy, but before long he thought there would be a great increase there, and that our motor manufacturing trade in this country would depend very largely upon the number of motors that were sent to the colonies. He himself made his first road motor in the year 1869, since when he had devoted very considerable attention to the manufacture of steam tramway engines. He ran a very large number of these at the mileage rate, and made money out of them. He then came face to face with the heavy repairs which were necessary in those steam tramway engines. It might be interesting if he mentioned that where only a small number of tramway engines — a small fleet, as the author had expressed it—was possible in a town, it was very seldom that that fleet of tramway or motor engines could be worked at a remunerative rate, because first of all it was necessary to have a really competent manager, without whom it was impossible to have the repairs properly done. A competent manager required a competent salary, and a competent salary could not be paid unless the company owned a considerable number of motors, which in their turn required first-class people to do the repairs, because from the moment the motors started repairs became necessary. The motto, "A stitch in time saves nine," applied with particular force to motors. The motor required to be run a very large number of miles per day in order to work it remuneratively. His tramway engines each ran 100 miles a day, and he was never satisfied unless they accomplished that distance. He made it the practice to have a temporary overhaul one day a week, and a thorough overhaul one day a month. In that way the repairs were kept reasonably low, and the cost of running only amounted to sixpence a mile, running for ten years. That was only done by keeping the tramway engines in good condition. He was borne out in his contention by the success which the large London motor companies had achieved. They had competent managers, competent workmen, and, above all, every part was in duplicate. The author had referred to the question of Government subsidies in connection with motor vehicles, and he quite agreed with Mr. Wyatt in regard to that matter. Turning to the question of motor cabs, these could only be run by large companies at a profit; small companies could not run them at a profit, as they could not pay the expenses of the necessary high-class staff to keep the cars in repair. That was the reason why the large companies had prospered. With regard to sending out motors to the colonies, in order to be

successful they should be sent out in large batches, unless there were a very considerable number of motors already in the centres to which they were being sent, so as to be able to maintain the necessary repairing staff. If a garage was opened in those centres, then a competent staff could be maintained, and the motors could then be worked successfully. He did not think that without such a system of garages the scheme of sending out motors to the colonies would be successful, but when such a scheme did come into force, he thought the author's suggestions would be eminently practicable.

Mr. HOWARD D'EGVILLE said that he had devoted very considerable study and attention to the defensive aspects of Imperial questions, and it was only in that connection that he ventured to offer some comments on the paper. He had been very much interested in the remarks which the author had made with reference to co-operation betweeen the dominions and the United Kingdom in relation to the supply of motor vehicles for military purposes. In regard to the question of subsidising motor vehicles, he took it Mr. Wyatt referred to the necessity of Dominion Governments undertaking those subsidies, because, as was quite well known, the great over-sea dominions were now attaining independent positions, and, in any question of co-operation for mutual defence, the War Office at home could not be expected to undertake subsidies in regard to the self-governing dominions, although of course it would undertake them in connection with colonies in East and West Africa, and other parts of the world. He quite agreed with the author when he said that the extent of the motor industry in this country was not at present adequately grasped by the over-sea dominions, and he cordially supported the suggestion of demonstrating to colonial visitors at the Coronation the true facts of the case. In that connection he thought the Festival of Empire would afford a splendid opportunity of showing to the colonies the great possibilities of the motor industry in this country, and would also be a guide as to what was possible to be done at the great Imperial Exhibition which was to be held in 1915. Referring to the appendix, he saw the author mentioned Ottawa as a typical Canadian town for the motor industry. He did not agree with that; he thought there would be better opportunities in towns of greater population. There were, in fact, tremendous possibilities in the west of Canada, and also in the maritime provinces which were not referred to. Mr. Wyatt, however, had made a most useful and suggestive contribution to the study of the question in which he himself was most interested—that of Imperial military organisation.

Sir PIETER STEWART-BAM said the author had touched on a question which could not be but familiar to everybody who had anything to do with the colonies, namely, that better attention should be paid to orders which were sent from the colonies to the Mother Country. He also thought that manufacturers in this country should advertise their wares more extensively. With regard to what was being done by motor power in the colonies, only a few months ago he saw his friend Mr. Dean, the Minister of Agriculture in Natal, at Cape Town on his way to England with the object of buying additional agricultural traction engines for use in Natal, as they had done such excellent work in that colony. That showed that even in agriculture motors were beginning to take a prominent part. And not only in agriculture, but in travelling. Motors were now in use all over South Africa, so much so that one wondered how people twenty or thirty years ago could have got over the country without them. He thought the author's suggestion as to making a subsidy in connection with motors, with a view to using them in time of war, was an excellent one. Just as horses had been useful in time of war so, he thought, motors would be. But, speaking generally, not only in the case of motors but of everything else, those in the colonies, as Britishers, had the feeling that they wanted to do as much trade with the Mother Country as they possibly could. In that connection, however, he thought the people of the Empire did not push themselves forward enough. He did not wish to touch on politics, yet he wished to point out that, despite the 10 per cent. preference on all British goods going into South Africa, the Americans and Germans got the business. He believed the British manufacturer did his best, but it ought to be better known what could be manufactured in the British colonies. That was why the Imperial Exhibition was going to be held in 1915, in order to show not only to colonials but to people in this country what could be manufactured and produced in this country. Exhibitions had been held for the last twenty years showing what foreign countries could accomplish, and it was high time that stock should be taken of what the Empire could do. But there was no need to wait till 1915; and he threw out the suggestion to Mr. Wyatt that he should get into communication with the Committee of the Festival of Empire to see whether the scheme he had put forward could not be carried out under their auspices.

Mr. W. WORBY BEAUMONT said the great difference between the author's valuable paper and most of those which had been read more or less on the subject in that room for some years was that, having now arrived at something approaching perfection with certain kinds of motor vehicles, manufacturers were now looking out for an extension of the trade in those vehicles, and the most interesting part of the paper was indicative of the directions that should be taken and of the methods to be avoided in obtaining that trade, and in obtaining the kinds of vehicles necessary in other countries. Manufacturers had come to the point where they wanted to extend the use of the

vehicles that had been made, rather than to create new types; and the author particularly referred to a type which, if suitable for much of the colonial use, would be, more or less, or perhaps wholly, suitable for military purposes. Agreeing with him to a very large extent on that point, he (Mr. Beaumont) was bound to say that the struggle to produce vehicles of the kind Mr. Wyatt was referring to, other than of the traction engine type, was a struggle which seemed perhaps to be inevitable for a time, but one which should be considered, and would, he thought, hereafter be considered only as a struggle to get over temporary difficulties, difficulties that at all events ought to be considered as temporary; for instance, improvement and extension of the roads. One of the great difficulties the author referred to with regard to the colonies was that of clearance, the distance between the lowest part of the machinery, etc., and the ground. Wherever the author referred to that, of course, he meant that a vehicle was wanted which should be capable of working satisfactorily where roads either were not, or were bad. Taking that as an indication of what had to be done, mostly in the future perhaps, the question arose: What kind of vehicles, tractors, or others could possibly be made at the present time which would satisfy colonial requirements? Most of those requirements could be satisfied at present with the type of lighter powerful traction engines which were being made by several firms in this country—by people who had had very great experience in the production and use of such engines. There were, however, certain regions, both at home and abroad, where the conditions were such that no one type of vehicle could possibly be equally useful or equally good in either different colonies or different parts of colonies. So it came to a selection of vehicles that would suit particular districts and particular kinds of work. Hence, although the author had referred to details, he had referred to those which would pertain, or which pertained, to different kinds; almost, if he might be allowed to say it, as though those details were all referring to one kind of vehicle. He would like the author to make it a little clearer that it was several types, at least, of vehicles that really were wanted, and, with reference to that, the proposed exhibition should be carried out so as not only to show the different types of the really useful, practical, and durable things that were made in this country, but to enable visitors to see that there were those different types, and that they could apportion them, as he might call it, to the different purposes and places that they had in mind. Some, however, of the types now being called for would become unnecessary, and would be replaced by others far more useful and profitable when the need for more and better roads was attended to. Referring to that part of the paper which dealt with the early failures and successes, the maintenance question — the examination and proper overhauling of the machine—was of the greatest importance. It mattered not how good the vehicles were, whether traction engines or tractors, steam or oil engines, or motor omnibuses, all must fail unless those who owned them recognised that the machines included in their structure parts which were of the most delicate construction, and parts which had to be attended to, not only when defects showed themselves, but before defects showed themselves. There must be proper workshops available, so that men capable of doing the work should be in sufficient comfort to do it properly, and to do not only that which was obvious, but that which had to be discovered. In saying that he was repeating what he had insisted upon in that very room in his series of Cantor Lectures in 1903, but he mentioned it again because even in this country, owners of vehicles costing hundreds of pounds allowed their motors to get into such a condition that the nine stitches became necessary where one would have been sufficient. If that sort of policy were allowed to continue, no perfection of construction or of material would be good enough to make an otherwise successful motor vehicle a profitable thing either in this country or in the colonies.

Mr. Dugald Clerk, F.R.S., said, as one who had been concerned with internal-combustion engines for some thirty years, it was a matter of no inconsiderable interest to him to find the internal-combustion motor applied to every variety of possible usefulness. So far as the heaviest of all traction was concerned, steam traction still held the first place, by means of the heavy traction engines which were famous all over the world as English engines, notwithstanding tariffs and everything else. He had great hopes, however, that even in the heaviest of traction work, the internal-combustion engine would take its place. At present the internal-combustion engine, especially in the form of a petrol motor, had been more applied to cases where the power was not so great as was required in those heavier engines, apparently because the petrol engine became, for very heavy power, somewhat expensive in its fuel. It was possible, however, to see a way to applying internal-combustion motors to those heavy traction purposes by the addition of a fuel which had not been mentioned by the author; it was quite possible to use in countries where there was no coal, wood charcoal and also anthracite, and it was possible to make a heavy traction motor with an internal-combustion engine requiring only coal or wood charcoal. There was as much experimental work going on in England as in any other part of the world in every possible line, whether in steam turbines or internal-combustion motors, and he hoped that, in the heavy traction movement, this country might keep as well to the front as she had succeeded in doing in the lighter traction movement. He wished to say one word in support of the British manufacturers. He did not believe people quite gave them the credit for the amount of advertising and the amount of searching that they undertook in order to get work in the colonies

The firms he was connected with had people all over the world, and they had no difficulty whatever in getting custom. Of course, some people asked for a special article, but in modern manufacture the great secret of success was standardisation and manufacture on a large scale. England need not fear entering all markets, protected or unprotected, because her manufacturers had paid great attention to cheapness of production and to the manufacture of goods of first-class quality.

Mr. WYATT, in reply, said the discussion had amplified and explained points which he had possibly slurred over, or had failed to make sufficiently clear, and for that reason he had listened to it with the greatest possible interest. The discussion, also, had given the audience an opportunity of listening to men who had had experience over an extent of country of which he himself could not claim to know even a small part. With regard to the particulars which he gave in the appendix, he had been dependent in almost every case on correspondents resident in those places, and that was the case with regard to Ottawa, which Mr. D'Egville mentioned. Several speakers had referred to the prime importance of full facilities of repair and maintenance, and there, he supposed, all were in absolute agreement. He thought that rather strengthened the case for his suggestion of subsidising vehicles which were in many respects suitable for colonial and also for military use. Those vehicles, in his view, would be of several types, and the preponderance of certain types would depend upon the district in which the fleet was being collected. If the subsidies were granted by the Governments of the dominions, the result would be that in each dominion the fleet would be of a kind most suitable for operating in that dominion, and at the same time would become valuable in response to similar subsidies offered in this country by the British War Office; there would be a combination of the various fleets available in the dominions, and a great percentage of it would be suitable for war in any part of the world. With regard to Mr. Dugald Clerk's remarks, he seemed to agree with him (the author) that the British manufacturer was not solely to blame. He did not say for a moment that he was not to a certain extent to blame, but, if he might say so, when it came to the point it would be found that where he was to blame was that when a customer came in and asked for something which he could not sell him, he did not sell the customer something else. It had been said that any salesman could sell a man what he wanted, but only a good salesman could sell him what he did not want, and he believed that was how the Americans got in front of Englishmen in a great many British possessions over seas. He was very much obliged to the speakers for supporting his suggestions. The first of these—the motor subsidies—was a matter which must be left on the knees of the gods; possibly something of the kind might materialise in the future. With regard to the second suggestion, he had got a more concrete, though a far smaller proposal. He had ascertained that a large proportion of the leading manufacturers in the industrial vehicle motor trade in this country would support some such proposal as that which he had attempted to outline. He thought the difficulty of inviting the co-operation of the promoters of the Festival of Empire would be that it would not be worth their while to go to the trouble of assisting in any way which would be of any great value, unless the Exhibition was a far more permanent thing than he himself proposed. They would not use their influence to bring really practical and valuable men down to see the vehicles. In that connection he was very fortunate indeed to have the advantage of the presence and the opinion of Sir Pieter Stewart-Bam. To ask him to take anything more than a passing interest in a matter of the sort under discussion was really like using a sledge hammer to crack a nut, but if Sir Pieter would do so, the success of the thing would be absolutely assured. With regard to the experiences detailed by the Chairman, there was one remark which he felt he might comment upon. The Chairman referred to the fact that motor cabs could be run by large companies, but rather implied momentarily that the small man or individual owner could not make his living out of it. He thought the Chairman meant that the small man, if he were isolated and had to depend upon himself for repairs and maintenance, could not make a living, but the remark might be misunderstood to mean that the individual owner in a big city such as London would not be able to make a living against the big company. He, the author, believed, as a matter of fact, that although the individual owner must pay for his repairs and maintenance more than the big companies paid for the repairs and maintenance of one vehicle, the personality of the man, if he used it properly, and his power of working up a connection, and his personal interest in his own business, would balance any disadvantages, and he would make a good living out of his cab as things stood at the present time.

On the motion of the Chairman, a vote of thank to the author was carried, and the meetin terminated.

THE INTRODUCTION OF PHOTOGRAPHIC TRANSPARENCIES AS LANTERN SLIDES.

By SIMON H. GAGE,

Emeritus Professor of Histology and Embryology, Cornell University.

It is hardly possible for the multitudes of the younger generation of professional and amateur photographers to comprehend that the entire development of photography, as a useful art, lies in the period between 1839 and the present; and that many men are now living whose activities include

this entire period, and who successively witnessed the rise of the daguerreotype (1839), the calotype (1841), the albumen picture on glass (1847), the collodion picture on glass (1851), and finally the gelatino-bromide dry plates of the present.

It is also difficult to appreciate, when viewing the successive scenes of the magic-lantern and of the moving-picture machine, that a very much greater number of men living at the present time have witnessed the entire development of the photographic processes necessary to make such an exhibition possible.

From the first the wonderful, almost magical art of photography fascinated a multitude of workers in all Western nations. Many of the processes and much of the apparatus were repeatedly and independently devised or invented by many individuals. It is natural therefore that, although a man may have lived during the entire development of the art, he would have exact knowledge about only those parts with which he has been personally connected. At least this was found to be the case in the effort to trace the origin of the now almost universally employed photographic transparencies for lantern slides in place of the hand-painted pictures first used in the magic-lantern by Walgenstein as early as 1665.

As finally worked out it was found that photographic lantern slides were introduced by at least two different parties working independently and entirely unknown to each other. One utilised the albumen process of Niepce de Saint-Victor, and the other the collodion process of Scott Archer.

I. *Magic-Lantern Slides by the Albumen Process*, 1850.—Two brothers, W. and F. Langenheim, daguerreotypists and owners of Fox Talbot's patents in America for negative and positive pictures on paper, were successful artists in Philadelphia. In 1850 the brothers issued a catalogue of photographic lantern slides made by the albumen dry plate process of Niepce de Saint-Victor in which the positives as well as the negatives were made on glass.

The first published account which I have found concerning these photographic lantern slides is by the physicist, Robert Hunt, in the *Art Journal* of London, Vol. III., N.S., April 1st, 1851, pp. 105, 107. Hunt says: "In the original French photographs on glass, the negatives only were received on that substance, the positive copies being received on paper . . . In the *Hyalotype* both the positive and the negative impressions are obtained on glass, and the result is as near an approach to perfection as we can imagine. The *Hyalotype* is the invention of Messrs. W. and F. Langenheim, of Philadelphia . . . the proprietors of Mr. Fox Talbot's American patent. These gentleman state of their process that . . . 'the distinguishing feature consists in the material on which the impressions are taken. We have substituted plate-glass for the paper in the negative and also in the positive, altering the process to suit the new material' " . . . Robert Hunt continues: "The most interesting application of this discovery is the construction of magic-lantern slides from nature by the camera obscura without the pencil or brush . . . We have now before us a series of these magic-lantern slides—the *Hyalotypes*—and we feel bound to declare that their delicacy and the perfection of the details cannot be overstated. In a view of Spring Garden Hall, Philadelphia . . . the delineation of the details is marvellous . . . A view of the United States Custom House in Philadelphia is in every respect equally perfect . . . In this picture, for the purpose of showing the facilities afforded by this process, a slight transparent tinting has been given to the trees, a neighbouring house, and the sky; and thus by the magic-lantern is produced a picture faithful in all its details, with the beauty of colours superadded . . . Already these photographic artists have published 126 views around Philadelphia, Washington, and New York, including Mount Vernon, and the Capitol at Washington."

Many of these photographic lantern slides were sent by the Langenheims to the first International Exposition—"Exhibition of the Works of Industry of all Nations," held in London in 1851. The official report of the jurors of this Exposition, p. 227, has this to say: "Langenheim (U.S. No. 62) . . . This artist also exhibits a series of subjects designated by him under the name of *Hyalotypes*, being delicate miniatures excellently adapted for magic-lanthorn subjects. The material would appear to be collodion, albumen, or some similar preparation forming a film on glass, capable of receiving the impression."

In the illustrated catalogue of the Exposition issued by th: London *Art Journal*, p. xii., this is said: "The *Hyalotypes*, or photographs on glass, both positive and negative (many of the pictures being coloured for magic-lantern slides), are pleasing applications of the [photographic] art."

The *Athenæum* for June 14th, 1851, pp. 631-2, in discussing "Photography in the Palace of Glass," says, concerning the matter in hand: "The *Hyalotypes*, or glass pictures, are of a remarkable character. They are but a modification of the process of Mr. Talbot and of M. Evrard as applied to glass; but the idea of copying Nature on this material—and having obtained a fixed picture of the shadowed image, of magnifying it by means of the magic-lantern, and thus producing a truthful representation of the original—is certainly due to the artist of Philadelphia. Many beautiful views of the Smithsonian Institution, of the Custom House in Philadelphia, and of churches in several cities of the United States, show the minuteness of detail which can be obtained by the use of the albumenised glass."

II. *Magic-Lantern Slides by the Collodion Process*, 1851-2.—Every new process in photography was especially welcomed and enthusiastically practised in America, hence almost immediately after the publication of the *collodion process* by Scott Archer in the *Chemist*, in 1851, the photographers of the United States were making use of it for the production of *ambrotype* portraits, and it soon became applied to the production of lantern

slides as follows: A young physician near Boston, Daniel H. Briggs, like so many of the New England physicians, wishing to aid in the education and improvement of the community in which he lived by giving public lectures, and having skill in drawing and painting, put this to use in making hand-painted lantern slides to illustrate the lectures he gave on anatomy and geology. Hearing of picture-making on glass by photography, it occurred to him to apply the method to making lantern slides. After receiving some hints from Whipple, of Boston, who was making *ambrotype* portraits, he succeeded in making lantern slides by photography of the subjects upon which he was lecturing. These he coloured to give them the natural appearance.

Dr. Briggs was so successful with his lantern slides that he taught his son the art. In 1872 they moved to Philadelphia. The son, Mr. C. W. Briggs, who still continues the lantern-slide business in Philadelphia, has kindly given the following: "The process of the Langenheims, I find upon comparison of dates with my father's first work, 1851-2, was entirely different. They coated the glass with albumen and used a dry plate in exposing, while my father used a wet collodion plate. Each party worked entirely unknown to the other." Finally, in 1875, the Langenheims sold out their entire business, including negatives, etc., to Mr. C. W. Briggs.

It is thus seen that photographic transparencies were applied as magic-lantern slides almost as soon as the albumen and collodion methods with glass plates were devised. Both methods lent themselves to the production of perfect slides, and the first makers applied colours, as had been done with hand-painted slides. In a word, photographic lantern slides were perfected in the very beginning.

It is interesting also that Dr. Briggs used his first slides for illustrating lectures upon anatomy and geology, that is, for instruction in these subjects which are so largely illustrated by lantern slides in lecture courses of the present day. The first slides of the Langenheims were of buildings and natural scenery, portraits, engravings, and of war scenes. In the very beginning, then, photographic lantern slides included the whole field of illustration.

NOTE.—The writer wishes to acknowledge the aid rendered in gaining the information given above. First to Mr. F. D. Langenheim, of Philadelphia, son of W. Langenheim, who gave many references and much information concerning his father and uncle. Fortunately the evidence of the work of the Langenheims is in print and accessible to everyone, as noted in the text above. Second, to Mr. C. W. Briggs, who gave me the information concerning the part played by his father, Dr. Daniel H. Briggs, in introducing lantern slides made by the collodion process. So far as known to me this information is now first printed. Third, it is with pleasure also that I acknowledge the numerous courtesies of the Secretary of the Royal Society of Arts, Sir Henry Trueman Wood, in making inquiries and forwarding information to me upon this subject.—S. H. G.

HOME INDUSTRIES.

Shipbuilding in 1910.—The most striking fact connected with the shipbuilding figures for 1910 is that while British shipbuilders increased their output of new tonnage, other countries show decreases. The shipbuilding output of the United Kingdom last year was prejudicially affected by the lock-out; but, notwithstanding this, the total of vessels built in the United Kingdom in 1910 was 1,163 against 1,097 in 1909, with a tonnage of 1,339,488, as against 1,181,528 in the previous year. On the other hand, the returns show that the foreign output of vessels in 1909 was 1,403, in 1910 it was only 1,236, with a tonnage of 1,094,569 in 1909, as against 1,012,170 only in 1910. Taking the 1910 figures, they show that the output of tonnage in the United Kingdom in 1910 exceeded by 327,318 tons the whole of the foreign output, and if the Colonial output is included in the British returns, the British superiority is still more marked. In 1910 the British increase in output was about 158,000 tons, while the foreign decrease amounted to 82,000. The decreases abroad are mostly in Germany, Holland, and France, the German output having decreased by about 60,000 tons, the Dutch by about 50,000 tons, and the French by about 12,500 tons. There was an increase in the tonnage output of the United States of about 70,000 tons, partly due to the launching of a battleship in New York dockyard, but principally to the building of more tonnage of cargo steamers on the Great Lakes. America ranks next in tonnage output to Great Britain, but not in ocean tonnage. It is a remarkable feature of American shipbuilding that it is almost entirely confined to vessels for lake and coasting services. In the seaboard yards there were hardly any vessels built of the tonnage of those turned out for the lakes. It must, however, be remembered that the figures quoted do not take into account any vessels of less than 100 tons gross. Also that while the warship tonnage launched in the United Kingdom was 8,415 tons displacement more than in 1909, the total for abroad in this respect registers a decrease of about 102,000 tons. It is also evident that the United Kingdom is year by year building less for other countries. The amount of such tonnage launched in 1910 was 223,463 tons, the lowest percentage of the total output since 1904. This remark does not apply to the British colonies, which remain our best customers for new ships. The sales in 1910 of United Kingdom vessels to colonial and foreign owners reached the record total of 513,618 tons.

Liverpool, the Shipping Industry, and Combines.—At the annual dinner of the Liverpool Shipping Staffs' Association, Mr. Thomas Royden dealt with the growth of Liverpool during the last two

centuries and the enterprise of Liverpool shipowners who took the lead in substituting steel for iron, and have been among the first to adopt every improvement devised by the engineer and naval architect, with the result that they have now the finest and fastest steamers in the world. In responding to the toast of "The Shipping Trade of Liverpool," Mr. R. D. Holt, M.P., made some observations upon recent absorptions which are well worth reproducing. He said he was not at all sure, as a Liverpool man, having the real interests of Liverpool at heart, that he liked to see the way the business of the port was being rolled up into gigantic concerns and combinations—some of them of a national and others of an international character. It was no good fighting against movements which had a solid economic foundation. If those combines did their work efficiently and economically it was not the slightest use kicking against them; they had to accept such conditions, but he confessed he did not like it. He did not like the tendency which deprived the town of a large number of independent persons, and there was no doubt it was a great misfortune. If they did not find an increase in the number of firms, independent people, and principals of firms, while at the same time the business of the port was increasing, it was really a misfortune to the town and district as a whole. He said that with some confidence, for he thought a great deal of the prosperity of Liverpool shipping, and the port of Liverpool had arisen from the fact—in the main—that the shipping had been controlled by Liverpool men born and bred in the town, living there most of their lives, and hoping to die there. He hoped when those combinations came about—if they had to come—that some of them would see that a fair portion of them were managed and controlled in the good old town.

Manchester and Australian Produce.—Mr. R. V. Billis, Mr. Hugh Mackenzie, and Dr. Elwood Mead recently visited England in order to find markets for Australian produce. They have now reported, and find that: (1) Other countries are doing their utmost to cater for the exact requirements of British buyers. (2) Under present conditions the Australian producer does not receive such good returns as he might. (3) One of the best markets in Great Britain is, so far, comparatively unexploited by Australia. Upon this last point the Report makes the following observations:—

"The undeveloped market is those densely populated counties Lancashire and Yorkshire, and indeed the whole of the west of England and Midlands and portions of Scotland, while the chief receiving and distributing centre for these parts should be Manchester. Undoubtedly a large portion of frozen meat, fresh fruit, and rabbits from Australia reaches Manchester and from there is distributed among the consumers of the west and north, but such produce comes *via* either London or Liverpool, and is subject to many handlings and to much unnecessary expense. The consuming population in the immediate vicinity of the Manchester Ship Canal is over 2,000,000. Within a radius of 75 miles, containing 177 important towns, there is a population of 12½ millions, and the Manchester docks are nearer to every one of these towns than any other port. Furthermore, it is the practice of buyers from more distant towns to visit the Manchester markets regularly, so that this city is in reality the mart or trading centre for an enormous population. Here is a community numbering quite twice the population of Australia and New Zealand, and it is a community possessing unusual purchasing capacity, still it cannot boast—or Australia cannot boast—a direct steamship service from Australia to it."

Railway Dividends.—The railway dividends already declared must be considered satisfactory. For the second half of 1910 the Great Eastern has declared a dividend at the rate of 4½ per cent., in comparison with 4 per cent. for the corresponding half of 1909, and with 3¾ per cent. for the second half of 1908. Great Eastern Stock may now be bought at about 70, which gives a yield of £4 12*s.* 3*d.* per cent. after allowing for accrued dividend. The Chatham dividend is also a good one, being at the full rate of 4½ per cent. on the first half year, with an increase of £32,700 in the carry forward, so that it is not unlikely that there will be a full 4½ per cent. for the year which ends on June 30th. An additional £41,000 received from the Joint Committee by the South-Eastern has enabled the resumption of dividends on South-Eastern Deferred. The Directors have announced a dividend at the rate of 6 per cent. per annum on the Undivided Ordinary in comparison with 5 per cent. a year ago. The dividend on the Undivided Ordinary for the whole of 1910 is 3½ per cent., which compares with 2¾ per cent. for 1909, and 2½ per cent. for both 1908 and 1907. The Central London Railway has done better. The dividend at the rate of 3 per cent. per annum on the Undivided Stock, giving 2 per cent. on the Deferred, is unchanged, but £8000 more is placed to reserve, and the balance carried forward shows a slight increase. The Metropolitan continues to show steady progress. Over 100,000,000 passengers used the line during the past year. In the past six months the gross receipts increased by £12,400, and a saving of £5,500 was effected in working expenses. The net profit has increased £20,800. A dividend at the rate of 1½ per cent. per annum is to be distributed as against only 1 per cent. for the corresponding period of 1909. The dividend for 1910 is 1⅜ per cent. against 1 per cent. in 1909, and ½ per cent. in 1908. The City and South London dividend is unchanged, namely at the rate of 1¼ per cent. per annum, but the balance carried forward has increased from £712 to £1788.

The British Silk Trade.—The expression of the

Queen's intention to use in her coronation robes silk made by British manufacturers has naturally given much satisfaction to the trade, and the Silk Association of Great Britain has just held a conference to consider the best means of increasing the trade in British silks. A good deal was said at this conference about the need for closer co-operation between the makers and the sellers. It is often said that it is difficult to get British silk, and that when obtained it is expensive and of inferior quality, but the truth of these statements is contested. It is not claimed that the British manufacturer can supply every kind of silk goods, but there is an increasing output of British silk which compares favourably in every way with foreign goods. What is wanted is the application of art and taste for design and colour to the technical processes of the trade. It was urged by more than one representative of the retail trade at the conference that the manufacturers should come direct to the retailer as foreigners do. Often the retailer does not know whether the goods brought to him are British or foreign. And the foreign maker seems to be more willing to study the requirements of the retailers. The merits of the spun silk in which the British firms excel should be more widely advertised. As it is, 90 per cent. of the silk supplied to the high-class dressmakers comes from France, Italy, and Switzerland. Patriotism is not sufficient to induce people to buy British silk. The manufacturers must pay greater attention to the wants of the public. The foreigner takes the greatest pains to find out where he is beaten in the English market, and to produce exactly what is wanted in finish and price. One of the difficulties of the business is that it depends on the varying demands of fashion, and the leaders of fashion go abroad for their ideas.

Tin.—At the end of 1909 tin was quoted at £153 per ton, at the end of last year it had risen to £174; it is now quoted at £190, and it may soon be up to £200 per ton. There was no substantial change in the visible supply of tin last year as compared with 1909 until December. At the end of November it was 20,500 tons, or much the same as a year earlier, but since then the visible supply has dropped to 17,910 tons, as compared with 21,385 tons a year ago, the shipments for December being much below the average, whilst those for December 1909 were unusually heavy. The probability is that prices will remain high and go somewhat higher than the present high quotation. Apart from market manipulations, there are two causes operating in favour of the producer. The tin plate industry, both in America and the United States, is remarkably active, and the falling off in the shipments from the Straits Settlements in 1910 was nearly 4,000 tons as compared with 1909 and 5,800 as compared with 1908, a shrinkage due to some extent to the scarcity of labour caused by the extension of rubber cultivation in Malaya. There is not much likelihood of other parts of the world supplying the deficiency.

OBITUARY.

Sir Francis Galton, D.C.L., Sc.D., F.R.S.—Sir Francis Galton died at Grayshott House, Haslemere, on the 17th inst., at the age of eighty-eight. A grandson of Erasmus Darwin and a cousin of Charles, it was natural and in accordance with his own theories that he should distinguish himself in a scientific career. Intending at first to enter the medical profession, he studied for a time at Birmingham General Hospital and at King's College, London, but in 1840 he proceeded to Trinity College, Cambridge, where, but for a breakdown in health, he would probably have gained a high place in the Mathematical Tripos. On leaving the University he spent several years in various parts of the then unknown Dark Continent, and in 1853 he published an account of his travels in the "Narrative of an Explorer in Tropical South Africa." For this work he received the Founder's Gold Medal of the Royal Geographical Society, and was elected a member of its Council.

Mr. Galton next turned his attention to the study of meteorology, and took a considerable part in devising the early weather charts which appeared in the *Times*. He also served as a member, and for some time as chairman, of the Managing Committee of Kew Observatory.

It was, however, in connection with anthropological science that his name is most widely known. In 1869 he published "Hereditary Genius: an Inquiry into its Laws and Consequences," in which his thesis was to show that genius is mainly a matter of ancestry. This was followed in 1874 by the appearance of "English Men of Science: their Nature and Nurture," which formed a statistical study of 180 men prominent in the English scientific world of that time, giving particulars of their ancestry, health, stature, size of head, etc., and in 1883 by "Inquiries into Human Faculty and its Development," in which he discussed the practicability of supplanting inefficient human stock by better strains, "thus exerting ourselves to further the ends of evolution more rapidly and with less distress than if events were left to their own course."

In 1895 Mr. Galton published his "Finger-Print Directories," and the system therein recommended for the purpose of identifying criminals has been adopted, with some modifications, by the Home Office.

Of late years most of Mr. Galton's attention was devoted to the problems of National Eugenics, defined by him as "the study of those agencies under social control that may improve or impair the racial qualities of future generations either physically or mentally." In 1904 he endowed a Research Fellowship in the University of London, and established a laboratory where an immense quantity of statistical information bearing on various lines of eugenic inquiry has been accumulated.

During the course of his long life Mr. Galton

received many honours in recognition of his scientific achievements. In 1855 he was elected a member of the Athenæum Club under Rule II. From 1857 to 1863 he was hon. secretary of the Royal Geographical Society; from 1863 to 1868 he acted as general secretary to the British Association; he was twice president of its Geographical Section and also of its Anthropological Section. In 1860 he was elected a Fellow of the Royal Society, which, in 1886, awarded him a Royal Medal in recognition of his statistical inquiries into biological phenomena, in 1902 the Darwin Medal, and in 1910 the Copley Medal. He also received the degree of D.C.L. from the University of Oxford in 1894, and that of Sc.D. from his own University in the following year, while in 1902 he was elected Honorary Fellow of Trinity College, Cambridge. In 1909 he received the honour of knighthood.

He joined the Royal Society of Arts in 1876, and read before it a paper on "Physical Tests in Competitive Examinations" in 1890. He also took the chair at several of the Ordinary Meetings.

Robert Forrester.—The death took place at Seattle, Washington, on the 19th December, of Mr. Robert Forrester, in his forty-seventh year. Born in Scotland, he graduated with honours from the University of Edinburgh, and shortly afterwards proceeded to America. In 1889, after studying the coal formations in the coal districts of Pennsylvania, he settled in Utah, of which territory he was appointed United States Coal Mining Inspector, and became well known throughout the States as one of the most reliable coal experts in the country. He also acted as Consulting Engineer to the Denver and Rio Grande and Western Pacific Railways. Mr. Forrester was a member of the Royal Geological Society of Edinburgh, the American Institute of Mining Engineers, and many other scientific bodies. He joined the Royal Society of Arts only last year.

Charles Letts.—Mr. Charles Letts, who died at the latter end of last year at the age of sixty-three, was a constant attendant at the meetings of the Society and took a lively interest in a variety of subjects. He was admitted as a solicitor in 1870, and was a member of the firm of Messrs. Letts Brothers. He possessed a large collection of London prints and other objects of literary and antiquarian interest, and was well informed on the history of the subjects to which he devoted his attention. He served on the Council of the London Topographical Society, and was a member of the Royal Institution, the Royal Society of Literature, and the Faraday Society. He joined the Royal Society of Arts in 1897.

Captain Thomas Bridges Heathorn, R.A.—The Society has lost an old member by the death of Captain Thomas Bridges Heathorn, which took place on the 23rd inst. at the age of eighty. He served through the Crimean War with the artillery of the Turkish contingent, and during the Indian Mutiny he commanded the mountain train at Kotah, and was afterward mentioned in despatches for the action at Chotah Oodeypore. In 1868 he served on the Committee of Armaments under the late Sir William Gordon. He was elected a member of the Society of Arts in 1862, and took part in the discussions on several occasions.

NOTES ON BOOKS.

Scientific Handicraft. London: J. J. Griffin and Sons, Ltd.

This bulky work of over a thousand pages, while professing to be a price list of the physical apparatus manufactured and sold by Messrs. Griffin, is really quite a useful textbook on the subject of such apparatus. The first edition of "Scientific Handicraft" was published in 1866, and was then a catalogue of the firm's chemical apparatus. The second edition, published in 1877, is in the library of the Society, and has constantly been used up to the present date as a very useful book of reference on the subject with which it specially deals. Later editions of their list of Chemical Apparatus have since been published by Messrs. Griffin, and the old book of 1877 is in many respects obsolete and out of date. But even now it contains a great deal of very valuable information, and is in frequent use. The present book, dealing only with physical apparatus, is more distinctly a catalogue than the earlier book, and it does not appear to contain the interesting notes with which the founder of the firm enriched his catalogue. But it nevertheless seems to be, like its predecessors, a very useful and convenient work.

The American Flag. Compiled and edited by Harlan Hoyt Horner. Albany: State of New York Education Department.

In this supplemental volume to the sixth annual report of the New York State Education Department, Mr. Horner gives a very complete and interesting account of the American flag. Its origin would appear to be wrapped in as much mystery as that of Mr. Yellowplush himself, for Mr. Horner dismisses as "pleasant tradition" the story of George Washington calling upon the young widow, Betsy Ross, at her upholstery shop in Philadelphia, and asking her if she could make a flag; and that thereupon they set to work together and devised a design of thirteen stripes and thirteen stars, which was the original form of the present banner. The flag's authentic history begins on June 14th, 1777, when the American Congress formally resolved: "That the flag of the thirteen United States be thirteen stripes, alternate red and white; that the Union be thirteen stars, white on a blue field, representing a new constellation." The flag appears

to have been first displayed on August 2nd at Fort Swanwix, which an American garrison was preparing to defend against the British forces. On that day the garrison was reinforced by a detachment of the Ninth Massachusetts Regiment, who brought news of the recently-enacted statute. It was determined, amid great enthusiasm, to make a flag at once. The fort was ransacked for the materials, which were finally found in a soldier's white shirt, a woman's red petticoat, and a piece of blue cloth from the cloak of a certain Captain Abraham Swartwout. This account is confirmed by a letter from the captain asking for cloth to replace that which was taken to make the flag. The steps by which the present design of the flag was evolved are carefully traced with the aid of numerous excellent illustrations. The book also includes a collection of songs celebrating the Stars and Stripes, which, if they do not always rise to the highest poetry, are never deficient in patriotic fire.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

February 1.—Philip Joseph Hartog, M.A., B.Sc., "Examinations and their bearing on National Efficiency." The Earl of Cromer, G.C.B., O.M., G.C.M.G., K.C.S.I., C.I.E., Vice-President of the Society, will preside.

February 8.—Captain A. J. N. Tremearne, B.A., D.Anth., "Some Nigerian Head-Hunters." Colonel Sir John Smith Young, C.V.O., will preside.

February 15.—George A. Stephen, "Modern Machine Book-binding." John Murray, J.P., D.L., F.S.A., will preside.

February 22.—Professor J. Wertheimer, B.Sc., B.A., "Water-Finders."

March 1.—Dr. Leonard Hill, F.R.S., "Caisson Sickness and Compressed Air."

March 8.—James Cantlie, M.A., M.B., C.M., D.P.H., "Plague and its Dissemination." Sir Shirley Forster Murphy, M.R.C.S., will preside.

Wednesday afternoon, at 4.30 o'clock:—

March 15.—Colonel Charles Edward Cassal, V.D., F.I.C., "The Adulteration of Food." The Right Hon. the Lord Mayor of London will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

February 9.—R. A. Leslie Moore, I.C.S. (retd.), "Indian Superstitions." Lord Lamington, G.C.M.G., G.C.I.E., will preside.

March 16.—Claude Hamilton Archer Hill, I.C.S., C.S.I., C.I.E., "Education in India."

April 27.—Sir Thomas Henry Holland, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord Avebury, D.C.L., LL.D., F.R.S., will preside.

May 25.—W. R. H. Merk, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

January 31.—F. Douglas Osborne, M.Inst.M.M., "The Tin Resources of the Empire." Sir William Hood Treacher, K.C.M.G., will preside.

February 28.—The Hon. Sir Richard Solomon, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "The Resources and Problems of the Union of South Africa."

April 4.—Captain R. Muirhead Collins, C.M.G., "Australia and her Resources."

May 9.—F. Williams Taylor, "Canadian Banking."

Cantor Lectures.

Monday Evenings, at 8 o'clock:—

Frederick Wedmore, "Etching." Two Lectures.

Syllabus.

Lecture II.—January 30.—"Modern Etching." Goya—Wilkie and Geddes—The Silence before the Revival—The great French Outburst—Méryon, Bracquemond and Jacquemart — Haden and Whistler—Themes mainly Landscape, Portraiture, Architecture—The Etching of To-day.

Professor Adrian J. Brown, M.Sc., "Brewing and Modern Science." Four Lectures.

Syllabus.

Lecture I. — February 6. — Introduction. Dr. Graham's Lectures Thirty-seven Years Ago—The Brewing Process a succession of Complex Biochemical Changes—Barley: Classification of types used by the Maltster—Barley from the Agriculturist's and Brewer's Points of View—Present Position of Knowledge regarding Characteristics of Malting Barley—Results of recent Experiments on Barley Cultivation in Ireland, etc.

Lecture II.—February 13. — "Malting." Constitution of the Barleycorn — Character of Changes during Germination—Investigations of the Biochemistry of Germination—The Barleycorn a highly-specialised seed, etc.

Lecture III.—February 20.—"The Mashing Process." The Chemistry of Starch and its Transformation Products—Protein Changes during the Mashing Process.

Lecture IV.—February 27.—"The Fermentation Process." Previous Treatment of the subject

by Dr. G. Salamon in 1888—The Pure Yeast Question in Brewing—Zymase and Modern Views of Alcoholic Fermentation—Nitrogen Assimilation—The so-called "secondary" products of Fermentation, etc.—Conclusion.

Professor J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

March 6, 13, 20, 27.

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

Dates to be hereafter announced:—

FRANK M. ANDREWS, "Architecture in America."

ARTHUR CHARLES DAVIS, F.C.S., Assoc.Inst.C.E., "The Manufacture and Testing of Portland Cement."

GEORGE B. HEMING, "Art Education in Jewellery and Goldsmithing."

Professor RAOUL PICTET, "Les Basses Températures."

Sir WILLIAM ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

HAL WILLIAMS, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

NOEL HEATON, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. F. Wedmore, "Etching." Lecture II. — "Modern Etching."

Geographical, Burlington-gardens, W., 8.30 p.m. Dr. H. A. Lorentz, "Recent Explorations in Dutch New Guinea."

British Architects, 9, Conduit-street, W., 8 p.m. President's Address to Students.

Actuaries, Staples Inn Hall, Holborn, W.C., 5 p.m. Mr. Henry William Manly, "Staff Pension Funds: The Progress of the Accumulation of the Funds; The Identity of a Valuation with the Future Progress of a Fund; The Manner of dealing with Funds which are Insolvent; and Sundry Observations."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. R. W. A. Brewer, "The Art of Aviation."

Engineers, Junior Institution of, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. L. W. G. Costello, "The Law Relating to Engineering." (Lecture VI.)

East India Association, Caxton Hall, Westminster, S.W., 5 p.m. Miss Hilda M. Howsin, "Race and Colour Prejudice."

TUESDAY, JANUARY 31...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. F. Douglas Osborne, "The Tin Resources of the Empire."

Illuminating Engineers, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Discussion on "Library Lighting."

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. W. Mott, "Heredity." (Lecture III.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Papers by—1. Mr. C. W. King, "Sand-Movements at Newcastle Entrance, N.S.W." 2. Mr. C. S. R. Palmer, "Fremantle Harbour-Works, Western Australia." 3. Mr. Gerald H. Halligan, "The Bar Harbours of New South Wales."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. T. G. Newmarsh, "Through Algeria to the Sahara."

WEDNESDAY, FEBRUARY 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m Mr. P. J. Hartog, "Examinations and their Bearing on National Efficiency."

Public Analysts, Chemical Society's Rooms, Burlington House, W., 8 p.m. 1. Annual General Meeting. 2. Dr. Philip Schidrowitz and Mr. H. A. Goldsbrough, "Note on the Detection and Estimation of Small Quantities of Antimony." 3. Messrs. G. E. Scott-Smith and John Evans, "The Analytical and Microscopical Examination of Compound Liquorice Powder." 4. Mr. Clarence A. Seyler, "Commercial Analysis and Arithmetic."

Builders, Koh-i-Noor House, Kingsway, W.C., 4 p.m. Professor Beresford Pite, "The Teaching of Building Construction and Architecture."

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. J. W. Willis Bund, "Ancient Bridges and their Impending Destruction."

THURSDAY, FEBRUARY 2...Women's Aerial League, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 3 p.m.

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m.

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. H. B. Baker and G. H. J. Adlam, "The Constancy of Water of Crystallisation in Hydrated Salts. Part I." 2. Messrs. H. Davies and F. S. Kipping, "Different Methods of Applying the Grignard Reagent." 3. Mr. A. H. Salway, "The Orientation of the Nitro Group in Nitromyristicinic Acid." 4. Mr. F. G. P. Remfry, "The Condensation of Aromatic Aldehydes with Nitromethane." 5. Messrs. A. Holt and J. E. Myers, "The Phosphoric Acids." 6. Mr. W. J. Jones, "The Determination of Solubility Coefficients by Aspiration." 7. Messrs. M. O. Forster and F. M. van Gelderen, "The Triazo Group. Part XVI. Interaction of Nitrosates and Sodium Azide."

London Chamber of Commerce, Savoy Hotel, Strand, W.C., 7.30 p.m. Dinner and Discussion on British East Africa, to be opened by Sir Percy Girouard.

London Institution, Finsbury-circus, E.C., 6 p.m. Professor Silvanus P. Thompson, "The Life and Work of Lord Kelvin."

Royal Institution, Albemarle-street, W., 3 p.m. The Astronomer-Royal, "Recent Progress in Astronomy." (Lecture III.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Rev. D. G. Cowan, "The Land of the Vikings, including the Island of Bornholme."

Roentgen Society, 19, Hanover-square, W., 8.15 p.m.

FRIDAY, FEBRUARY 3...Royal Institution, Albemarle-street, W., 9 p.m. Mr. A. E. Shipley, "Grouse Disease."

Civil Engineers, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. W. Henry Hunter, "Rivers and Estuaries." (Vernon-Harcourt Lecture.)

Geologists' Association, University College, Gower-street, W.C., 7.30 p.m. President's Address on "Flint and Chert."

SATURDAY, FEBRUARY 4...Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. Hassall, "Problems in the Career of the Great Napoleon." (Lecture III.)

Journal of the Royal Society of Arts.

No. 3,037. VOL. LIX.

FRIDAY, FEBRUARY 3, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

PUBLICATION OF THE "JOURNAL."

In consequence of the threatened strike in the printing trade, it has this week been found necessary to go to press at a much earlier date than usual, and therefore it has been impossible to include in this number a complete report of the discussion on Wednesday's paper. The portion omitted will appear in the next issue.

NEXT WEEK.

MONDAY, FEBRUARY 6th, 8 p.m. (Cantor Lecture.) Professor ADRIAN J. BROWN, M.Sc., "Brewing and Modern Science." (Lecture I.)

WEDNESDAY, FEBRUARY 8th, 8 p.m. (Ordinary Meeting.) Captain A. J. N. TREMEARNE, B.A., D.Anth., "Some Nigerian Head-Hunters." Colonel Sir JOHN SMITH YOUNG, C.V.O., will preside.

THURSDAY, FEBRUARY 9th, 4.30 p.m. (Indian Section.) R. A. LESLIE MOORE, I.C.S. (retd.), "Indian Superstitions." Lord LAMINGTON, G.C.M.G., G.C.I.E., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday Evening, the 30th inst., Mr. FREDERICK WEDMORE delivered the second and final lecture of his course on "Etching."

On the motion of the Chairman, Mr. ALAN S. COLE, C.B., a vote of thanks was accorded to Mr. WEDMORE for his course.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, January 31st, Sir WILLIAM HOOD TREACHER, K.C.M.G., in the chair. A paper on "The Tin Resources of the Empire" was read by Mr. F. DOUGLAS OSBORNE, M.Inst.M.M.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A Meeting of the Indian Section was held on Thursday, January 19th, 1910, Sir FELIX SCHUSTER, Bart., presiding.

The paper read was—

BANKING IN INDIA.

By REGINALD MURRAY.

In dealing with this ponderous though important subject I will first describe the conditions of trade finance in India before joint-stock banking became a prominent factor, and, as my own experience goes back sufficiently far for the purpose of such description, I will confine myself to facts which are within my own personal knowledge.

I will, then, refer to the various incidents which have contributed, during the last fifty years, to set back India's credit in the City of London, and why I consider that India as a field for investment offers much securer and more varied opportunities for investment of sterling capital than has been recognised hitherto by London capitalists.

Until the English system of banking was introduced in the interior as well as at the coast-ports of India, trade was financed chiefly by a class known as "banias," hailing for the most part from the Province of Marwar, who combined trading with money-lending and finance. In addition to these there were the Chetties of southern India, who were more money-lenders than traders, and the Bhattias and Parsis of Bombay and Guzerat, who were almost exclusively traders. It has also to be borne in mind

that nearly every native of India, more especially perhaps in Bengal, is a money-lender at high rates of interest to needy neighbours whenever he has more cash in hand than he requires for his own immediate wants. Money-lenders on a large scale are called Sahucars and Mahajans. All such money-lending continues, but the finance for the transport of merchandise from one part of the country to another is now passing more and more into the hands of the joint-stock banks, and the money-lenders themselves are making use of these banks for deposit and remittance. Where there are still no banks, as in the agricultural districts, the old money-bag system still prevails, a system which may be termed plutocratic. For by it the possession of money is individualised and distributed slowly within contracted circles, while the joint-stock banking system is democratic, collecting and distributing impartially from and to a large portion of the whole of India. Under the old system, if high rates of interest or some fancied form of security were not available, the money-lender would sit tight on his money-bags. At times he would be advised by his Jogi or Sunyasi, or holy ascetic, that it was an unpropitious time to invest. Some persons, especially large zemindars, believed it added to their importance and popularity to display huge piles of money-bags on rent days and festive occasions. One way and another, before the introduction of the joint-stock banking system, the total amount of currency lying idle must have often exceeded Rs. 50 crores, or five hundred million rupees (£33,000,000).

For holding or hoarding purposes coin and bullion were preferred, and it can therefore be easily understood how much time and trouble it took to count and weigh them when they were being taken in to the hoard, and how slow and laborious was the task of restoring them to circulation; consequently, how extremely inelastic was the finance of trade, and how the system encouraged—and still encourages, where it is continued—organised bands of dacoits or armed robbers.

With regard to set-backs of confidence which have done so much to discourage London capitalists from embarking in Indian enterprise, I would refer you to the serious collapse of India's credit produced in 1866 by the extraneous influence of the cessation of the American Civil War. I might have first mentioned the Indian Mutiny of 1857, but that was before my time, and the set-back was not so important, as trade at that time had not been opened up to large proportions by the construction of the Suez Canal, and the extension of Indian railways.

Still, notwithstanding the evidence of India's subsequent prosperity, it is apparent that either distance or the more attractive gilding of mining ventures elsewhere, or Chilian nitrates or rubber, or humanitarian exaggeration, have in some way contributed towards raising the mirage of another mutiny on the Indian horizon.

Though the temporary collapse of trade in 1866 caused a set-back, the previous few years of unexampled though adventitious prosperity had opened the eyes of all concerned to the potentialities of India. The Indians of the Western Province were quick to grasp the situation, and the great strides which have since been made in trade and industry in the Bombay Presidency have been largely due to the praiseworthy enterprise and business capacity of the Jewish, Bhattia and Parsi communities of Bombay and Guzerat. Indian enterprise in the Northern Provinces has also been very marked of late years; but the larger industries of wool, cotton and leather manufactures in the North, of jute and cotton manufacture in Bengal, of tea cultivation in Assam, Darjeeling, and, together with coffee in Southern India, of oil and coal-mining in Bengal and Burma, of gold-mining in Mysore, and the large fleets of coasting and river steamers were all initiated and are still for the most part supported by British money and control.

The next set-back to India's credit in London was the instability of the exchange between India and England. Up to the year 1870 exchange seldom fell below 1*s*. 10*d*. per rupee, the par being 2*s*. Thereafter, commencing with the demonetisation of silver in Germany, the price of silver began to fall. By 1876 the gold value of the rupee had fallen to 1*s*. 6*d*., in 1886 to 1*s*. 4*d*., in 1890 to 1*s*. 2*d*., and in 1893, about the time the mints were closed or a few months later, transactions were reported in the neighbourhood of 1*s*. 0¾*d*. During these years the United States made strenuous efforts to resist the fall of the metal which was so seriously affecting their own country, but the steps taken of buying up large quantities of silver had only the effect of disclosing supplies more than equal to the demand, and greater collapse ensued as soon as their buying ceased. The wide and violent fluctuation in the sterling rate of the rupee affected trade in India, by making it more subservient to exchange than responsive to supply and demand; it restrained sterling capital from flowing to India owing to the

prospect of redemption at a loss; and it made the fiscal policy of the Indian Government the sport of the elements. The remedy of closing the mints, and subsequent legislation upholding the value of the rupee at 1*s.* 4*d.*, has been completely successful, and owes its organisation in a large measure to the able and masterly advocacy of an Indian banker, the late Mr. A. M. Lindsay, of the Bank of Bengal.

The complete success of the reformed system of Indian currency was triumphantly proved during the crisis of 1907–8, and there is no longer any reason why fear of instability should deter the flow of sterling capital to India.

The third set-back was the Boer War. Why it should have been so is unexplainable, but there is the fact that while money was poured like water on to dust-heaps in Rhodesia, not only was Indian enterprise neglected, but it was, and I believe still is, a common instruction from investors to London brokers to avoid even Indian Government sterling securities for private investment, notwithstanding the comparative steadiness of rupee-loan paper in India.

This comparative steadiness is remarkable because the rupee loans issued in India since 1896 have been subscribed to almost entirely by Indian investors, and must have totalled over Rs. 20 crores, and in addition, according to the returns of the Public Debt Office in Calcutta, the holdings of rupee paper in London, which were represented as over Rs. 26 crores in 1896, now stand as under Rs. 14 crores, and the holdings of Indian investors have thus been further increased by Rs. 12 to 13 crores.

Now, when every cause of alarm engendered by previous circumstances should have been allayed, India is again set back by a catch-phrase derived from the headlines of newspapers, "Unrest in India." As a flare to distort the countenances of political adversaries such a phrase may be termed applicable, but if it is applied to the condition of India, and more especially to Indian trade and financial stability, there is no more tune in it than in a watchman's whistle.

It is sometimes said that the acts of violence and seditious propaganda of a few ill-balanced Indians are the result of western education. But what I am more sure of from my own experience of forty years in the East, spent mostly in India, is that western education and association with western people have taught them much better than they had realised before "what pays," and have taught them to appreciate a better style of living and freer opportunities of enjoyment. They have no ambition to go back to the days when famine was unrelieved, and when bands of freebooting sepoys spread over the land, looting as they went. The Indians are not fools. They are realising that however old and good a form of civilisation may have been it cannot stand still; that the world, linked up as it is now by rapid means of communication, cannot exist in sections; that they must join the universal throng or perish in solitude; that saintliness and respect for custom are excellent qualities when opposed to immorality and uncleanliness, but when opposed to honest and intelligent aspirations they exceed their mission. In aspiring to a larger share of government they are courting a democracy which could not endure amid the ancient forms of intense conservatism, and in the evolution towards more liberal and, I may add, less selfish and cramped ideals, the progress of banking is having a powerful and practical educative influence. As Mr. John Bright said in one of his famous speeches: "Is custom to be venerated because it is old, or ought we not rather to affirm with Cyprian that custom without truth is agedness of error?"

These, Mr. Chairman and gentlemen, are the preliminaries which I have desired to place before you, and which, after demonstrating the progress of banking, I may advert to briefly again at the end of this paper as claiming for India a fair meed of confidence and credit, and for the banks a share in having had a corrective and stimulating influence for the general weal.

Dealing now with the progress of banking, I will review shortly the history of the introduction of English banking into India.

Until 1809 there were no chartered or joint-stock banks on modern lines in India. The mercantile houses acted as private bankers for Europeans, and the Indian shroffs conducted the trade finance. Indians universally kept each his own money in his own house. The first chartered bank was the Bank of Bengal, which received its charter from the East India Company in 1809. The Governor-General at that time was Lord Minto, the distinguished grandfather of the Viceroy who has just retired, to enjoy, we may hope, many years of leisure and the well-merited thanks of his countrymen after five years of arduous and successful work under unusually difficult and almost exasperating circumstances. The fact that at least twelve new Indian banks were incorporated under the Act, and that there was such an extensive development of trade and finance, as I will presently show you,

during those five years is evidence of the confidence reposed in Lord Minto's administration, as is also the fact that the so-called "unrest in India" had no more effect upon local credit than it had upon his patience and unbiassed discretion.

The first Bank of Bombay was established under a similar charter in 1840, and the Bank of Madras in 1843. Under the early charters the Government was a shareholder to the extent of about one-tenth of the capital. The banks were authorised to issue notes against a proportion of Government securities lodged with the Accountant-General, and the Government exercised the right to nominate three officials on the board of directors. The circulation of notes up to 1862 appears never to have exceeded Rs. 2 crores in Bengal, Rs. 1½ crores in Bombay, and Rs. 20 lacs in Madras. In 1862 the privilege of issue was withdrawn from the banks, and the note circulation from and after that year has been issued solely and exclusively by the Government. At first the banks, now known as the Presidency Banks, were employed as the departments of issue and payment of the Government currency notes; but in 1867, after the commercial crisis, the Government set up a separate currency office where the entire control of the note circulation and of the reserves held against the same is separately administered. The total active note circulation, according to recently-published statements, is about Rs. 53 crores as against Rs. 13 crores in 1890, and Rs. 9 crores in 1870. The reserve held by the currency office at the present time is Rs. 41 crores in coin and bullion, Rs. 10 crores in Indian Government securities, and the equivalent of Rs. 2 crores in English Government securities.

Statements of the circulation and the reserves held are published weekly, and it is difficult to conceive a more perfect, more public, and more automatic system, one which bears constant evidence of redemption at call, and which contracts and expands exactly according to the requirements of the community, no more and no less.

About the same time—that is, in 1867—the Government ceased to be a shareholder, and in lieu of privileges withdrawn the new charters contained an undertaking on the part of the Government to keep with the Presidency Banks a minimum balance in cash from the civil treasuries, and to assign to the banks as a Government Department the management of the Public Debt. In consideration of this support the Government retained, and still retains, the right to nominate three members of the board of directors.

Of the banks with sterling and dollar capital and head offices in London and China, there are now existing only four of those which were existing in 1870 and earlier, and only one now existing was added up to the end of 1909, since which one more has commenced business. My progressive statement, presently to be shown, contains the figures of the first five banks only, and as regards deposits those in India only. Capitals and reserves are totalled in sterling and dollars, but, beyond showing a measure of prosperity, cannot be taken as money employed solely in India, as all the banks have branches in other countries. The deposits in India correctly or approximately show, so far as these banks are concerned, the growing popularity of banks as places of deposits in substitution for vaults and holes in the ground and other hiding-places. These banks have now thirty-two branches in India.

Forty years ago there was only one Continental or foreign bank represented by branch establishments in British India, now there are five. I have not included these in my progressive statements, as, although they do employ a considerable amount of capital in the Indian trade, it is improbable that they have many rupee deposits.

The Presidency banks had forty-six branches in 1870, thirty-eight in 1890, and fifty-three in 1910. The banks incorporated in India other than the Presidency banks have, with few exceptions, been established during the last twenty years. There were two with two branches in 1870, five with sixteen branches in 1890, and thirty-five with 220 branches in 1910. Of the last-named, sixteen had capitals of Rs. 5 lacs and upwards, with 161 branches, and nineteen had capitals of less than Rs. 5 lacs, with fifty-nine branches. I will now refer you to Appendix I.

The figures of this appendix are of banks now existing; nearly all have been kindly supplied to me by the banks themselves, and the others come from the India Office library, and should, therefore, be approximately correct. Numerous small banks may have been omitted, but none, I believe, whose figures would materially alter the result. Also it must be brought to notice that a few banks and banking concerns which held considerable deposits failed or closed between 1870 and 1890, and between 1890 and 1910. The actual increase in deposits between 1870 and 1890 was probably less than is shown in the appendix, as there was considerable

distrust occasioned by the continual fall in exchange during that period, and probably most of the deposits recovered from failed banks which are not included in the total of 1870 were remitted to England. Since 1890, and especially since 1900, I think it may be assumed that the deposits of banks which have closed business have, for the most part, been transferred to other banks, but even if we were to take deposits in 1890 as Rs. 1 crore more on account of banks which have closed, and whose figures are not shown in this appendix, it would still leave a colossal proportion of increase in 1910.

I have included in my Appendix I., Table B, foreign trade, and Table C, railways and canals, in order to show the concurrent progress in trade, in the means of communication, and in the aid to agriculture. The coasting trade, of which I have not given the figures, has increased from about Rs. 12 crores to about Rs. 50 crores during the period under review.

About thirteen years ago, and always before that time, the circulation of money in the chief cities of export did not keep pace with the advance of trade, industry and railway extension. At the end of 1897 the rate of interest in the Presidency towns jumped from 5 to 9 per cent. within a month, rose to 12 per cent. in February, 1898, and did not fall below 7 per cent. till July. The rains of 1896 had failed and caused famine in 1897, and consequently the warehouses in the Presidency towns overflowed, necessitating large advances from banks and others. There was not sufficient money in the Presidency towns to finance the produce which arrived after the succeeding good autumn harvests, and this insufficiency of money did not arise because money was not in the country, but because there was no machinery for moving it when wanted from the interior to the Presidency towns. In this connection, and as explaining the meaning I wish to convey in the figures of the appendix before you, I take the liberty to quote an extract from an article which I contributed to *Capital*, the leading financial paper of Calcutta, in 1900 or 1901.

"What we want is a gauge to the financial capabilities of India, both for the successful enterprise of trade, industry and agriculture, and for the true economy of Government administration. I have no hesitation in asserting that no truer gauge can be obtained than by the extension of the joint-stock banking system.

"Railways and canals . . . have gone ahead . . . steamers are increasing annually in size and speed . . . Progress has been very marked in the extension of tea and jute cultivation, and in all kinds of agricultural produce. Manufacturing industries have sprung up in all parts of India, and coal-mining has advanced with rapid strides.

"The only motive power which has not kept pace with the general progress of the country is the most important and, up to the present time, the most neglected. I refer to the machinery for attracting, economising, and distributing credit and money.

"That this factor has been neglected is apparent in the dearth of working capital. Hardly is there an industrial concern in India which is not frequently hampered by want of working capital. Hardly ever does a busy export season occur without finding the Presidency towns bare of loanable funds. The coasting and internal trade is chronically brought to a standstill from want of discounting facilities, and even municipal, port trust, and Government loan securities are occasionally unmarketable.

"All this has been recognised for some time past, and has seemed to point to a deficiency of capital in a poor country. The Government of India conceived that the best way of introducing capital would be a State bank with large capital. Obviously, however, the first thing to do is to exploit the capital within the country before resorting to the more expensive and less efficient method of borrowing from abroad. The best-known method of exploiting capital is by the extension of the joint-stock banking system, because it is only by this system that capital can be automatically concentrated and distributed. That the joint-stock banking system extends over a very contracted area in India is evident from the small aggregate amount of deposits held by the banks . . . This is not, as is often supposed, due wholly, or even chiefly, to the hoarding habits of the native population, but it is largely due to the fact that there are not bank offices, branches or agencies situated within convenient reach of would-be depositors."

This extract shows what heavy calls there were upon India, progressing in everything but financial facilities, and how the extension of banking was the obvious remedy.

The appendix proves the correctness of the diagnosis by showing that the remedy has been adopted with extraordinary readiness in all three Presidencies, and markedly in the Punjab. I remember receiving in 1903 a letter from a Punjabi, whom I did not know, saying that, after reading my pamphlet (one then published), he was determined to keep no money in his house

in future, but to open a deposit account. I think he may have been moved by what appeared upon the last page of the pamphlet, which I will exhibit to you. (*See* Appendix IV.)

The total increase of deposits during the last twenty years has been not less than Rs. 50 crores, and in addition the capital and reserves of local banks have increased over Rs. 6½ crores. The inference may be drawn that a considerable part of this large sum of money thus put into circulation has come from hoards, or money privately stored, and I consider that this inference stands good even after allowing for the larger volume of sterling money now lying temporarily in India attracted by the effective working of the Currency Reform Act of 1893.

The effect of the increase of banking capital and deposits in the interior has been the necessity to look to the Presidency cities for investment, and consequently nearly all of these up-country banks have opened branches or agencies in the Presidency towns to employ a portion of their resources. In this way money which would remain idle for some months if left in the interior has been remitted to the Presidency towns, and has replenished the supply of money there, so that, notwithstanding the last two seasons of good harvests and large exports, the Government has not been called upon to coin any fresh rupees for over two years, and money in the Presidency towns has been at no time under strain. You cannot fail to realise what a great advance this is—finance cheapened and money flowing to the points of greatest pressure; also money making money which formerly ran to waste through unemployment.

This great progress is to my mind important, not only in regard to what has been accomplished, but also as to what may still be accomplished, and although I will not guarantee to live another twenty years in order to prove it, I will venture on another diagnosis.

I foresee that the banking progress, great and rapid as it has been, is only a commencement. The volume of deposits will increase in those towns where banks have already been established, and will certainly be stimulated if some of the smaller banks amalgamate with each other or with larger ones. You will see by the map which will now be shown to you, that there is plenty of room for further extension. The towns at which banks are established are underlined in red. When you consider that the eleven leading joint-stock banks in London alone have 2,588 bank offices and £474,000,000 in current and fixed deposit accounts, and allow for the larger population and smaller individual wealth in India, as being, for the sake of comparison, a set-off one against the other, the only conclusion can be that banking in India, though showing signs of vigorous growth, is still in its swaddling clothes.

The Marwari or Bania class, to whom I have already alluded, is one to which India is greatly indebted, more indeed than to any other class, for financing the agriculturists, and in moving produce from the growing to the consuming districts and distributing goods of all kinds all over the continent from our most northern frontiers to Cape Comorin. Banks are not in any way a hindrance to their trade; on the contrary, they must greatly assist them. The banks relieve them of much trouble and risk. Carrying about and secreting bags of rupees are no longer necessary when banks are handy. At present there are almost no banks in agricultural districts, but when they are established in the market towns of those districts, as they are certain to be sooner or later, both Marwaris and many others will find it convenient to make deposits and employ the banks for remittance. The general circulation will be very largely increased and facilitated when these districts are linked up with a system which will then become universal.

What may and should attract banks to agricultural districts is the growing popularity of co-operative credit societies. By advancing to these societies a fair interest would be obtained, and, as argued below, it should be an advantage to the Government to assure such advances against loss. I am entitled to speak about co-operative credit societies, because I had the honour to serve on the committee which framed the Bill, and I am therefore fully cognisant of the objects and reasons and all that these societies were hoped to effect. It was naturally some years before they could be explained and understood in more than a few districts. The stout, but by no means obstinate conservatism of the agriculturist had to be satisfied that the innovation was for his benefit. He had to gain confidence in his own powers to administer his own village finance; to rely upon himself and not upon the money-lender. The latest reports indicate that the system has now, so to speak, "caught on," and, if so, it is likely to spread all over the continent of India. Everything will depend upon the funds forthcoming to give these societies a start, and in this I think joint-stock banks may find it profitable to take some share. I believe that some advances have been

made by the Government, and others by syndicates of zemindars and wealthy tenants who are interested in the good cultivation of their lands. But such advances will cover a comparatively small number of societies, and if, as appears probable, further aid will be necessary, an inducement to joint-stock banks to come in would be offered if the Government could guarantee the advances. This should not be difficult, as every society is organised and afterwards conducted under Government supervision. Considering that in the aggregate considerable advances have, as I understand, been made direct by Government to these societies, and in the form of private loans to individual agriculturists called "taccavi," no greater risk would be run by giving a guarantee to banks. Provincial expenditure would thereby be economised. The banks, by being encouraged to establish themselves in agricultural districts, would cheapen the finance for collecting and transporting produce and for importing necessities and luxuries, besides having, as elsewhere, an educative and stimulating influence.

My remarks have now portrayed the past and sketched the possible future progress of banking in India. Before concluding, I think I may usefully state what my experience and observation suggest as steps needful to be taken to safeguard this progress from the perils to which a too hasty advance is liable to give birth. A common caution, which, though not always practised, is probably more respected in commercial than in political circles, is "look before you leap." In commerce and banking, Credit, with a capital C, is the great regulator. It has been said that Credit lives at No. 1 the World. If it is abused the abuser suffers. It is a solid, unchangeable and impartial standard of commercial soundness and thoroughness, and is impervious to the attacks of malcontents and the ignorance of popular clamour. Its veto cannot be disputed.

Reverting to my suggestions, I think it may be desirable that the Government of India should consider the advisability of refusing to register banks with less than a minimum of paid-up capital. Some proportion should be fixed between the amount of capital (including reserves) and the amount of deposits. Deposits stand in relation to the public in much the same position as bank or Government currency notes, for which an adequate reserve is universally enforced. It would be very undesirable that the Government of India should enforce safeguards by means of an inquisitorial department, but there is no reason why an Act controlling joint-stock banks should not be passed. The Indian Companies Act of 1882, under which banks are classed promiscuously with other joint-stock companies, is, in many instances, unsuitable for modern banks. The nature of a bank's business is, in some respects, the antithesis of that of other joint stock companies. The business of the former is to lend, of the latter to borrow; the one to grant and protect credit, the others to exploit it. One Act cannot be worded to conform to both classes of companies, and, moreover, banks, as I have pointed out, need some special safeguarding clauses.

In this connection another Act is required in India. The Indian Companies Act stipulates that all companies' balance-sheets shall be certified by auditors, but no definition is given of the duties, responsibilities, and qualification of auditors. If banks are to be safeguarded by Act of Government for the protection of creditors and shareholders, the Government must either appoint its own inspectors to see that the Act is conformed to or must pass such an Act as will make professional auditors responsible, and clearly define their duties and responsibilities and the limit of their powers. Such auditors and no others should be qualified to certify banks' and other companies' balance-sheets.

One more word about credit. Credit in England is a real living force, a standard around which no fuss is made, but none the less respected as the safest vehicle of finance. I am under the impression that Indians have the same respect for, and appreciation of, credit, and may be relied upon to conduct banking with discretion and with a strict regard for integrity. I add these remarks because we have so often seen a rise of banking contain unpleasant history. In some countries credit is extolled and set up like a marble statue, a thing of beauty without life. It is in such countries only that banking enterprise is dangerous. Credit may be said to be the religion of trade. It protects, but cannot be protected except by observance of its principles.

ADDENDA.

Since writing this paper I see from the Indian papers that the Upper India Chamber of Commerce have made some valuable suggestions for amending the Indian Companies Act of 1882, and recommend, in the interest of all concerned, some amendments in the Act to define more clearly the limit and sphere of action of companies registered as "banks." They refer to forty-seven new banks having been registered

in 1908–9, with paid-up capitals aggregating a little over Rs. 3,00,000, whereas I include in my list only three banks established in those years with a total paid-up capital of slightly over Rs. 1,50,000. If, therefore, there have been forty-seven new banks opened, it means that forty-four of them have a total paid-up capital of a little over Rs. 1,50,000, or less than Rs. 4,000 each, and it would appear, therefore, that the registration of banks is subject to no limits as regards capital.

In turning to Appendix II., "Statistics of British India for 1908–9," I find only sixteen local domiciled banks included, and of these two were defunct. It is explained that all banks whose aggregate of capital and reserve are less than Rs. 5,00,000 are excluded, and also the numerous small native money-lending and pawnbroking establishments which are registered annually as "banks" under the Indian Companies Act.

You will see from my list that the nineteen banks included as having capitals and reserves of less than Rs. 5,00,000, have deposits of Rs. 1,75,00,000 = £1,166,666, which, I think, is too large a sum to be neglected. I suggest also that the registering of small money-lending and pawnbroking establishments as "banks" is a somewhat promiscuous exercise of authority.

These additional notes and remarks add force to the suggestions already put forward that some legislation is desirable to check the abuse of, and serve as a regulator for, a system which has an extensive influence for the good in every country in which the true principles of credit guide its operation.

APPENDIX I.

TABLE A—BANKS.

	1870.	1890.	1910.
Presidency Banks—			
Capital	Rs. 3,36,25,000	3,50,00,000	3,60,00,000
Reserves	,, 25,57,000	1,02,74,000	3,17,50,000
Deposits (excluding Government balances)	,, 8,58,62,000	9,24,23,000	33,82,34,000
Increase in Deposits	—	7½%	294%
Five Exchange Banks—			
Capital	£2,351,000	2,353,000	2,899,000
	$3,500,000	7,500,000	15,000,000
Reserves	£191,000	670,000	2,690,000
	$700,000	4,400,000	29,500,060
Deposits	Rs. 2,82,21,000	7,11,76,000	20,07,32,000
Increase in Deposits	—	152%	611%
Sixteen Local Banks—			
Capital Rs. 5 lacs and upwards	,, 9,50,000	28,50,000	2,64,16,000
Reserves	,, 1,15,000	11,42,000	95,37,000
Deposits	,, 17,61,000	2,15,88,000	19,22,89,000
Nineteen Local Banks—			
Capital less than Rs. 5 lacs	,, —	—	26,01,000
Reserves	,, —	—	6,41,000
Deposits	,, —	—	1,74,98,000
Total Deposits, Local Banks	,, 17,61,000	2,15,88,000	20,97,87,000
Increase	—	1,126%	11,770%
Total Deposits, deducting from Presidency Banks one-third, as representing the Deposits of other Banks	,, 8,92,23,000	15,43,79,000	63,60,09,000
Increase		73%	613%

APPENDIX IV.

Reasons why Everyone Should Deposit their Savings in Banks.

1. If money is kept in a private house it attracts thieves. If thieves come to take money they may take lives as well.

2. If money is kept in a house or in a hole in the ground, the possessor earns no interest. On all money deposited with banks a depositor receives interest which is paid half-yearly.

3. Money deposited in banks is more readily available, and gives the owner less trouble than money kept in a house or buried; because if he wants to make a payment, instead of opening boxes and counting coins and notes, he writes a cheque and the bank takes all the trouble for him. Similarly, if a depositor receives payment by a cheque, instead of going a journey and collecting the money himself, he sends the cheque to his banker, who saves him the trouble without charge.

4. Keeping money on deposit with a bank costs nothing, but, on the contrary, yields a bi-annual return. Money kept in a house or buried costs much time and trouble, and if strong rooms or vaults are built, or iron safes purchased, the expense is considerable.

5. If the custom of depositing savings with banks were generally adopted by natives of India, I calculate that they would in the aggregate be richer by about Rs. 1 crore per annum. This is computing deposits at an average of R. 1 per head only, and allowing for an average return of interest at 3 per cent.

DISCUSSION.

The Chairman, in opening the discussion, said the paper was a most interesting and suggestive one. His own experience of Indian banking was limited, and only derived from observation in this country, while his knowledge of India was due to five years' work at the India Office. The pleasure of visiting the country had so far been denied to him.

The paper was divided into two parts, the first dealing with the question of Indian credit generally and the position of that credit in this country, and the second devoted to the question of banking. The author had alluded to a set-back in Indian credit in London, and had referred to the opportunities afforded by India for the investment of British capital, being of opinion that those opportunities were not taken advantage of to their full extent. He did not altogether agree with Mr. Murray that there had been such a set-back in Indian credit. The price of India stock no doubt had fallen considerably, like all other gilt-edge securities, but he did not think the price of Indian sterling Stock had fallen more in proportion than that of British Consols. If there had been a set-back in credit it was due to many causes which affected securities generally, and not those of India alone. He did not think personally that the unrest, of which the newspapers had made the most, had affected the minds of investors to any great extent. In order to develop the resources of the country the Government had had to borrow very freely during the last few years, and the proceeds of those loans had been devoted to a great extent to the construction of railways, but the loans had been well taken up by the British public, and were held not for the purpose of speculation but for investment. He had no doubt that in any future issues the Government of India might make, there would be plenty of capital found for Indian enterprise, as long as the public was satisfied that the loans were really used for the construction of railways and the development of the country. With regard to the opportunities for investment in commercial directions, he did not think they had been offered to the public to such a large extent as they might have been. He did not remember having seen a prospectus of Indian industrial undertakings. It might be the duty of the bankers themselves, if they wished to foster such enterprise, to bring it before the public in a proper way, and he had no doubt then that the capital would be forthcoming. The fixed price of the rupee, which he was glad to say had withstood the hard and difficult times of two or three years ago and proved its stability, would also tend to move capital into India provided that opportunities were given. There had not been a fair chance yet, because, owing to the conditions of the money market, due to the Boer War and other causes, the value of money on this side had often been higher than the value of money in India, and naturally money had remained in this country instead of being invested in the East. Given another set of conditions and a return to cheaper money, he thought money would flow into India. As to the progress of banking generally, the author had pointed out the great progress that had taken place and the advantages offered to the trade of the country. He should like to have asked the author many questions on the matter if time had permitted answers to be given. For instance, he should like to have known something about the relations subsisting between the exchange banks and the Presidency banks; whether the Presidency banks acted in the same way as the Bank of England did towards the other joint-stock banks in this country; whether they kept balances with the Presidency banks, and also what their own rules as to the conduct of business were; and

whether they kept a fixed proportion of cash against their deposits. The difference between British banking in India and native banking also he should like to hear explained; to know whether the native banks were conducted on different principles and what the distinction was between the two, if there was any distinction at all. He was particularly struck with the success of the banks. The management being in India and the boards in London implied that a great deal of initiative and responsibility were in the hands of those to whom the institutions were entrusted. He thought it was a good system that the responsibility should rest on the executive officer, with a supervising board behind him. It developed strength and independence of character, and that capability of dealing with difficulties which marked the very highest qualities of mind. He believed that the Indian bankers were some of the best bankers ever seen. It was only another development of the administration of the country generally, an administration in the hands of responsible officers, unfettered but responsible to their superiors. While the author had spoken of the success of the banks, it should be remembered that the success had not been always unchecked, and one would like to hear of the disasters and the causes that brought them about; for instance, what really led to the downfall of the Oriental Bank, one of the most powerful institutions existing at one time. A good deal had been heard of the cry that India was short of capital, and that might be true. It was a cry he always liked to hear. He was always delighted when he heard there was a great deal of congestion on the railways, because where there was congestion there was business, and where there was business there was always a cry for fresh capital. That was what had taken place, and what he hoped would take place in the future. The author had said that banking in India was only just beginning; he quite agreed with him, in fact he believed that the trade of India generally, and the welfare of the country, was only in its infancy. Given a period of rest and freedom from political agitation both in India and at home, he felt confident that, with the development of the railways, with the benefits bestowed by irrigation, with the care of the Government for the well-being of all classes, the commercial development and prosperity in the next ten to twenty years would be such as was almost undreamed of at the present time. He believed the possibilities of the development of India were as great as, if not greater than, those of any of the British colonies, all of which gave such great promise for the future.

Mr. H. M. Ross did not think the author had exaggerated the importance to India of the extension of banking, and there was ample scope for the employment both of the gold capital of this country and of the funds which the banks would be able to command locally. Apart from the unrest question—which he agreed in regarding as a transient one—there could be no doubt that the employment of gold capital in India would depend upon the maintenance of the gold standard, the establishment of which had placed the trade and the banking of India upon a new and secure footing. The author's residence in India embraced a period before and after the change of standard, and his experience of a banker's anxieties in the early part of that period must still be fresh in his memory. For his own part, he should never forget the troubles of a merchant at the time when, as Mr. Murray so aptly expressed it, the violent fluctuations in the sterling rate of the rupee made trade in India more subservient to exchange than responsive to supply and demand. The progress and prosperity of banking in India had been extraordinary. About the time of the closure of the mints the £20 paid-up shares of the Chartered Bank of India, then established for forty years, stood at £18; fourteen years after the closure, in 1907, the shares were sold as high as £70. The National Bank of India had in the past few years distributed in the shape of bonus-shares to its shareholders a sum equivalent to 60 per cent. of its original share capital, and at the same time had paid handsome dividends year by year. With such remarkable results it seemed very strange that the great significance of the proposed change of standard of banking in India was not at first appreciated by bankers themselves. With one or two exceptions they lent little or no countenance to the agitation for the closure of the mints. Of course the first essential of sound banking was prudence, and a banker who was likewise an agitator was no doubt a dangerous man. The author had hazarded a prediction with regard to the future of banking in India which the Chairman had thoroughly endorsed. Banking in India would increase enormously with the development of the vast natural resources of the country, and in such a development banking would play its part. The extension of banking in India would be materially assisted by facilities for obtaining funds in the cheapest market, and that at times would mean the English market. This necessitated the absolute maintenance above all doubt and suspicion of the gold standard. None, he thought, were more conscious of the vital importance to India of the maintenance of the gold standard than Sir Felix Schuster and his colleagues on the Council of India, and it was with the utmost confidence that responsibility might be left to them for the maintenance of that standard. The author had mentioned an alternative to the employment of gold capital by making local hoards and resources available by an extended system of banking. In a letter appearing in the *Times* about two years ago, and endorsed by the paper in a leading article, his friend Sir Ernest Cable, of Calcutta, urged the desirability of usefully employing the vast hidden wealth of India. He did not know that it was economically correct to speak of the precious metals as wealth, but they could be exchanged for wealth. For years India had been absorbing the precious metals, and despite the improvements in

banking, was taking more than ever before. Of late years the net imports of treasure had averaged over twenty millions sterling. That might be a proof of increased prosperity, but it was also a proof that vast numbers of the population of India still knew no better method of disposing of their savings than by investing them in gold and silver. He had read lately in a circular of a London bullion dealer that precious metals were a necessity in India, not a luxury. But they were a necessity just because of the ignorance of the population, and that ignorance banking might do something to correct. A good deal had been heard about the drain of wealth from India, but in his opinion the real drain of wealth from India lay in the fact that year by year she parted with large quantities of her valuable products in exchange for a mass of metal of which she made no use. It was, however, a matter for thankfulness that there was no chance of the inborn habits of the natives of India being changed very suddenly. If, in the course of a few years, they reversed the practice of centuries, by ceasing to import the precious metals and throwing large quantities of past accumulations on the market, it would certainly be very unwelcome, because there would be no knowing to what depths of depreciation the precious metals might go. The maxim, "look before you leap," quoted by the author at the conclusion of his paper would be an admirable maxim for the Government of India to consider when it had before it a Bill for giving a guarantee to joint-stock banks for lending their funds to agriculturists.

Sir JAMES WILSON, K.C.S.I., said he had not much knowledge of joint-stock banking, but he had had occasion to study the question of banking in India from the point of view of the agriculturists, and had often to consider how best to supply the agriculturists with the capital required to carry on agricultural operations. In the Punjab the ordinary rate of interest that had to be paid by a small peasant for petty loans to enable him to tide over a bad season or sow his grain was something like 20 per cent. per annum, and in some other parts of India it was reported by responsible officials that something like 37 per cent. per annum was the usual rate of interest paid by the peasant for petty loans. In other parts of India it was a good deal less. In Guzerat the agriculturist could often borrow for 10 or 12 per cent. A very large proportion of the agriculturists required to borrow money to carry on their work, and a high rate of interest was a tremendous burden on the prosperity of the small holders. In the Punjab there were something like one and a half millions of men owning rights in the land and cultivating the land themselves, and he had roughly estimated that the amount of money which they had to borrow every year in the Punjab alone was something like ten millions sterling. The population of the Punjab was about one-fifteenth of that of India, so that according to that estimate the small agriculturists of India had to borrow something like 150 millions sterling every year and pay 15 or 20 per cent. interest upon it. Those figures lent support to the author's prognostication that banking in India was still in its infancy, notwithstanding the wonderful progress already made. With regard to the amount of capital available in India to finance not only agriculturists, but all industrial and commercial businesses, he had seen estimates of the amount of gold and silver collected by the Indians and hoarded within the last 100 years, and he thought he was within the mark in saying that there must be 400 millions sterling of gold and silver either used in the form of ornaments or for currency, including 200 millions of gold and silver hoarded away. If the people could only be persuaded to lend the money instead of burying it in the ground, that gold and silver alone would probably be enough to finance all that India required without any help from outside at all. There were indications that the Indians were becoming more ready to trust their money to other people. As the author had pointed out, the money invested in Indian stock had increased considerably within the last ten years, and there was also an increase in the circulation of currency notes, which meant that people were more ready to take as money a bit of paper signed by the Government. There was no fear, however, of the whole population of India suddenly throwing 100 millions of gold and silver on the world's market—it would be a gradual process. He would like to see also a development of the banking system, which meant an extension of credit. He was glad to see that the number of small joint-stock banks was increasing and that the Punjab took the lead in the matter. He had been watching the growth of the small joint-stock banks in the Punjab, which were mostly managed by Indians, and there was a great danger that men who were not capable of managing a bank would start them and that credit would suffer by the bursting up of small banks. He agreed it was time the Government took steps to save the shareholders and depositors, and even the directors themselves, from the consequences of ignorance. Perhaps the best plan would be to lay down a limit that the deposits must not exceed so many times the amount of the paid-up capital; and also there should be a law to the effect that no bank with a paid-up capital of less than a lac should go on without a compulsory Government audit. It was not necessary to apply a compulsory Government audit to the well-established large banks, but the small banks should be looked after in that way. The author and he had had the advantage of serving on the committee which first drafted the Co-operative Credit Societies Act, and he himself had been able since to do something to foster the movement. He was chairman of the first meeting of registrars of co-operative credit societies and had had also to look after the actual working of the societies in the Punjab, and he rejoiced to see how very rapidly the movement was growing in India. It had caught on and promised to be an enormous success and of great advantage to the small peasant

proprietors. Although the Act was only passed about six years ago, there were already 2,000 co-operative credit societies in working order with 200,000 members. They were managed by the people themselves. That movement could not have gone on without assistance from the Government, and the chief assistance was rendered through the registrar, who was a Government officer, and mainly through a free audit. Every little society had to send in its accounts to the registrar, and he or one of his staff visited the village and went through the books and checked the whole of the work of the bank. The consequence was that not one of the societies had failed in such a way as to cause loss to anybody. In the Punjab the society generally lent to their members chiefly for productive purposes at something like 9 per cent., whereas the village moneylender used to charge 20 per cent. or more. Each man was interested in seeing that the borrower, his fellow-member and neighbour, paid up, and there had been very few bad debts. The movement promised to have a very excellent effect in supplying capital at a low rate of interest to the small village communities. The joint-stock banks could undoubtedly help in that direction by lending money to the co-operative societies, and one of the joint-stock banks in the Punjab said they were willing to advance a considerable sum at 6 per cent. to any society the registrar thought might safely be entrusted with the money without any guarantee from Government. He was very much in favour of co-operative societies, but much opposed to any suggestion that the Government should guarantee advances, because that would destroy the whole principle of the movement, which was to encourage thrift and good management and honesty amongst the people.

The CHAIRMAN, in moving a vote of thanks to the author, said that one point of difference between them was that Mr. Murray said it was the business of companies to borrow and the business of banks to lend. It was, however, too often forgotten that, of all borrowers, banks were the greatest. A bank's business was to borrow first in the shape of deposits and then to lend, and it could only lend as long as it borrowed. In any legislation that was attempted—he did not believe in very much legislation on banking matters—it had to be borne in mind that the very essence of a bank's business was to borrow money from the public in the first place. With regard to registration and audits, one of the great objections to a Government audit was the creation of a false feeling of security. A Government audit might be very useful in detecting mischief, but it should not create a feeling in the minds of the public that, because an institution had had the benefit of a Government or official audit, all was well. An audit was extremely valuable, but it could not be taken to guarantee the absolute safety and well-being of any institution. Therefore, if Government inspection implied more than that, generally speaking, everything was in order and fairly properly kept, as far as the books showed, there would be a great danger in such a step. The public had to learn to distinguish between banks and banks, and between institutions that were well managed and those badly managed, and they had to trust those who were in charge of them.

Sir WILLIAM LEE-WARNER, G.C.S.I., in seconding the motion, said the guarantee the Government could give was for the maintenance of peace within and without India, the guarantee of justice, and a guarantee not to meddle with other people's business. He trusted those were the only three guarantees the Government would give either to co-operative banks or any other banks, or any business private or otherwise. He had felt considerably cheered by the paper that had been read, because he felt there was a great scope for development in India. He believed the longer the British were in that country the more hoarding of gold and silver there would be, but that hoard would take new directions, *e.g.*, pictures, fine buildings, etc. He also wished to thank the Chairman for coming at a great sacrifice of his time to preside over the meeting, and he could assure Sir Felix Schuster that he would have even a heartier welcome the next time he came.

The motion was carried, and the meeting adjourned.

In reply to the discussion, Mr. MURRAY writes:—I am exceedingly glad to receive Sir Felix Schuster's assurance that India's credit in the City of London is as good as he states, and I trust his remarks will be noticed by the general public and their prejudices removed. With reference to his questions, the Presidency banks of India do not control the money market as the Bank of England does; but as all banks and large mercantile firms, municipal port trusts, and other public corporations, the administrator-general and official trustee, and numerous private persons in all towns where Presidency banks have offices, deposit a considerable portion of their daily surplus cash with those banks, and as the latter publish weekly statements of their assets and liabilities, they indicate the state of the money market. Then, as Council bills are paid through the Presidency banks, and they are the principal depositary for gold coin and cash, they are necessarily the chief distributors of currency, and thus the indication which they give of the position of the money market is approximately correct. The Presidency banks allow no interest on current accounts; other banks in the coast-port towns allow 2 per cent. per annum on daily balances from Rs. 1,000 to Rs. 100,000. The Presidency banks, under their charter, are restricted from dealing in foreign exchange (Ceylon excepted), except for remitting their customers' money and covering dividends payable at Coutts' Bank in London.

There is no fixed proportion of cash retained against deposits, but all the banks, Presidency, exchange, and local, make a practice of holding not less than 25 per cent. in cash.

Native joint-stock banks are understood to be worked upon the same general principles as European banks, except in some instances in which trading is combined with banking. The class of investment varies with the district in which the banks are situated. European banks do not as a rule lend upon mortgage of immovable property, but the nature of the trade and industries necessitates more loans of a fiduciary character than is probably customary in London.

The failure of the Oriental Bank was the result of bad debts, incurred principally in Ceylon. The bank had been the chief support of the coffee planters, and from advancing in growing crops, they went further and advanced on the estates. The leaf disease ruined the coffee planters, and the bank was too seriously involved to stand against its losses.

I do not think, though I express myself with diffidence in the presence of such a high authority, that deposits with banks can be classed in the same category as loans to trading companies. Money at short call may be so classed, but except in the Presidency towns during busy seasons, such deposits form a small portion of the deposits in India. The ordinary deposits are made, not as loans, but for the convenience and security of the depositors. Moreover, in the case of current accounts, they return little or no interest. My point is that in India, where the people, other than Europeans, are only just being encouraged to recognise the convenience and security which deposits with banks afford, it is of some importance that they should not receive discouragement, and with so many new banks springing up, many of which must necessarily be under inexperienced management, it is to be feared that banking enterprise may receive a check unless some regulations are made for the protection of depositors. I feel sure that it would be acceptable to the banks generally, and would not fetter legitimate business, if they were compelled by Act of Council to keep an adequate reserve in cash against their deposits, and if new banks were restrained from receiving deposits until a sufficiency of capital for banking purposes had been not only subscribed but paid up.

Referring to the remarks made by Sir James Wilson and Sir William Lee-Warner, I fully appreciate the objection to Government guarantees as a general principle, but in this instance co-operative credit societies stand in a similar position to railways, which are guaranteed. Their object is to increase cultivation, and with the attainment of that object the Government revenue will be increased, and the condition of the people bettered. The risk is balanced by the prospective benefit, and the benefit is of a kind which will be greatly enhanced by quick attainment.

EIGHTH ORDINARY MEETING.

Wednesday, February 1st, 1911; the Right Hon. the EARL OF CROMER, G.C.B., O.M., G.C.M.G., K.C.S.I., C.I.E., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Bell, A. Mitchell, 56, Stanley-road, Halifax, Yorks; and Municipal Technical College, Halifax, Yorks.

Hill, W. Hereward, Canton, China; and Fairmount, Sidcup, Kent.

Hope, William Henri, The Studio, South Croydon, Surrey.

Miles, T. R., 9, Brighton-terrace, Brixton, S.W.

Osman Sahib, Khan Bahadur S.M.V., B.A., B.L., Presidency Magistrate, Madras, India.

Pillai, Perumana Narayana, Kayangulam, Travancore, India.

Sykes, John Guttridge, 88, Marlcliffe-road, Hillsborough, Sheffield.

Young, Rev. William Edward, Brook Lawn, Queen's-road, Teddington.

The following candidates were balloted for and duly elected members of the Society:—

Armsby, Henry Prentiss, Institute of Animal Nutrition, Pennsylvania State College, State College, Pennsylvania, U.S.A.

Beaumont, Frederick, 6, William-street, Lowndes-square, S.W.

Bebb, Charles H., Denny Building, Seattle, Washington, U.S.A.

Blain, Alexander W., M.D., 1105, Jefferson-avenue, Detroit, Michigan, U.S.A.

Chirol, Valentine, Queen Anne's-mansions, Westminster, S.W.

De Wardt, John Isaac, 82, Pelham-road, Gravesend.

Dowding, J. C., Chinwangtao, North China.

Eyde, Sam, Sommerrogaden 15, Christiania, Norway.

Fahy, John Thomas, A.M.I.E.E., New Zealand Railways, Wellington, New Zealand.

Finn, Herbert J., 23, Sandgate-road, Folkestone; and c/o The Modern Gallery, 61, New Bond-street, W.

Flower, Charles E., Warborough, near Wallingford, Oxon.

Hogg, Rev. William Charles, 116, East Third-street, Williamsport, Pennsylvania, U.S.A.

Kakting, Robert, c/o Messrs. O. W. Lindholm & Co., Vladivostock, Siberia.

Kean, Athelstan Joseph Alexander, P.O. Box 50, Guanajuato, Guanajuato, Mexico.

Lord, William Henry H., A.R.C.A.(Lond.), 24, The Pavement, Clapham Common, S.W.

Mackenzie, Roderick D., 9, St. Paul's Studios, Colet-gardens, West Kensington, W.

Martin, Miss Cicely Bridget, 3A, Church-road, Upper Norwood, S.E.

Menzies, Dr. F. N. Kay, 79, Davies-street, Berkeley-square, W.

Millar, Alex. H., LL.D., F.S.A.(Scot.), Rosslyn House, Clepington-road, Dundee.

Millar, F. Grahame, Tangga Batu Estate, Malacca, Straits Settlements.

Newman, Miss Florence, Garlinge, 14, Templar's-avenue, Golder's-green, N.W.

Pannett, Robert Elliott, J.P., Whitby, Yorkshire.

Peat, William Barclay, F.C.A., 11, Ironmonger-lane, E.C.

Powelson, W. V. N., 60, Wall-street, New York City, U.S.A.

Quinton, Alfred R., Westfield, Salisbury-avenue, Church End, Finchley, N.

Sunder, Donald Herbert Edmund, F.L.S., c/o Messrs. Grindlay & Co., Calcutta, India.

Tatlock, Miss H. H., 16, Park-square, Regent's-park, N.W.; and Bramfield House, Halesworth, Suffolk.

Tower, His Excellency Reginald T., C.V.O., Traveller's Club, Pall Mall, S.W.

Waley, Alexander Simon, 32, Rue Spontini, Avenue du Bois de Boulogne, Paris, France.

Westervelt, William Young, 100, William-street, New York City, U.S.A.

Whittemore, Harris, Nangatuck, Connecticut, U.S.A.

Youngman, Miss A. M., R.I., Porton, Salisbury, Wilts.

The paper read was—

EXAMINATIONS IN THEIR BEARING ON NATIONAL EFFICIENCY.*

By P. J. Hartog, M.A., B.Sc.

May I begin with a personal explanation? What I have to say to-night is said on my own behalf alone, and no one else in the university which I have the honour to serve must be regarded as committed in any way to agreement either with my main thesis or with any incidental opinions I may express.

To avoid all possible misunderstanding, I shall state my position at the outset. I desire to appear neither as counsel for the plaintiff nor for the defendant in the great controversy on examinations which has raged intermittently for more than half a century in this country, as in other countries, but rather as one of the public, deeply interested in the issues, and trying to see clearly through the heat and dust of the conflict.

It is often said, and generally accepted, that the whole of English education is controlled by the examination system. It is well, however, in dealing with educational questions, to keep somewhere in the back of one's mind the fact that there is another kind of education than the education of the schools, the education that Mr. Samuel Weller's father gave him when he let him have the run of the streets and make shift for himself; well to remember that there is one branch of the national activity, not the least successful or important—I mean its commerce—which up to the present has been but little affected by examination-ideals; and that our agriculture and industries have been affected by them only to a minor extent. Our business, our agriculture, our industries, have to a large extent "shifted for themselves," I will not say without the help of school teaching, but very largely without the help of examinations.

But the public demands that persons on whose services it relies, but for whose failures it cannot be compensated, as by a business man who fails to fulfil his contract, that these should produce some certificate of competency based on an examination, and often on a series of examinations beginning in childhood, and prolonged into early manhood and beyond. Teachers, lawyers, doctors, dentists, engineers, architects, and the civil, naval and military servants of the Crown, on whom the organisation and defence of the Empire rest, must pass examination tests, and in many cases their whole career is determined by such tests.

It is, therefore, a matter of national and Imperial concern that this method of test should be wise in its design, certain and not capricious in its working, and, above all, that in its stamping operations it should not damage the human material on which it sets a hall-mark.

Can it be said of English examinations at the present day that they fulfil these requirements? Are they wisely designed? Do they work with certainty and accuracy? Do they tend, on the whole, to improve the boys and girls, the men and women, whose education, whose lives and careers they so largely control? Are they really serving the national and Imperial purposes they are supposed to serve, in the best possible way? If these questions were put to a Referendum, I have little doubt of the reply.

While it may be conceded that there are many judicious examiners, and examining bodies

* I have made considerable use in this lecture of the article on Examinations by my friend, Mr. Arthur Watson, and myself, just published in the eleventh edition of the "Encyclopædia Britannica." The reader interested in the subject should refer to a largely-signed protest entitled "The Sacrifice of Education to Examination" (by no means out of date), with replies thereto, published in the *Nineteenth Century* for November and December, 1888, and republished later by Auberon Herbert (Williams & Norgate, 1889).—P. J. H.

of unquestioned wisdom, the body educational as a whole is suffering from the aches and pains of examination. Those who say, "Get rid of examinations altogether," offer us nothing in their place; they do not realise the situation. I spoke just now as if examinations affected us only from without; but have not examinations become, as it were, an artificial nervous system of our education, of which every movement is controlled either by their stimulus or by their power of inhibition, so that extirpation is an impossible task? If we cannot remove this tyrant that governs education from within, cannot we either reduce its powers or force it into beneficence? Quixotic as it may seem, I believe the task not to be impossible.

The task demands inquiry—and by inquiry I mean scientific investigation — patience, and perhaps some drastic reform later. My object to-night is to suggest, first of all, the outlines of an inquiry into our examination system, its design, its methods, and its results; and I shall use the word "examination" to mean a systematic test of knowledge, and of either special or general capacity or fitness, carried out under the authority of some public body.

First of all, the design of examinations. We cannot understand that design without one word as to their history and their original function. The origin of Western examinations —I say nothing of those Chinese examinations which date back three or four thousand years— is sufficiently well known to the historians; they are derived from the examinations of the mediæval universities. Those universities were corporations of teachers and students, analogous to the trade and craft gilds of the time. In the gilds there were apprentices, companions, and masters. No one was admitted to mastership until he had served his apprenticeship, nor, as a rule, until he had shown that he could accomplish a piece of work to the satisfaction of the gild. The object of the university was to teach; its scholars, bachelors or pupil teachers, and masters or doctors, corresponded roughly to the three classes established by the gilds, and the master or doctor (two terms at first equivalent) was one who, having served his apprenticeship and passed a definite technical test, had received the *licentia docendi* —the permission to teach. The candidate was required to teach in public at the examination precisely as he would be required to teach later in the schools. The examination fulfilled exactly the technical purpose for which it was intended. We are apt to think of the schoolmen and all their ways with a contempt inherited from the days of Bacon and Descartes; but in discussing examinations of this kind, that distinguished historian of education, the late Professor Paulsen, of Berlin, asserts that they were well adapted to increase a student's alertness, his power of comprehending new ideas, and his ability quickly and surely to assimilate them to his own; and that they did more to enable students to grasp subjects than the mute and solitary reviewing and cramming for our modern examinations can possibly do. The limitations of the test were the limitations of the educational and philosophic ideals of the time. At their best, as I say, they did exactly what they were required to do. At their worst, says Canon Rashdall, they were less of a farce than certain English University pass examinations almost within the memory of persons now living.

To trace the history of Western examinations from their origin to our own time would require us to follow up the ever-changing course of educational ideals with the development of modern societies through seven centuries, and the manifold actions and reactions during all that period between education ideals and examination ideals. For such a task we have not even the materials prepared; but, remembering that the original examination was a test of technical efficiency, excellently suited to its purpose, we can see how examinations have taken on two, and perhaps three, entirely new functions, and with far-reaching effects both on examinations and on education.

The first new function—the use of examinations to distinguish between candidates of different merit—was an early and almost inevitable development; and yet we can see every day how the competitive idea leads us to forget the distinction between the efficiency of an examination and its difficulty. It is constantly said by examination-enthusiasts: "This examination is a superior examination to that, because it is harder to pass." Should we not rather ask: "Is the man who passes it a more useful member of society?" In examinations professedly technical, like the original examinations, this question is of the utmost importance. The main question there is surely not which candidate can do the most difficult things, solve the most Chinese of puzzles, remember the most unrememberable of formulae, but, is the examination helping to turn out the best teachers, doctors, engineers, industrial botanists, industrial chemists? In other

examinations, like the highest Civil Service examinations, the element of pure difficulty, on which I shall have a word to say later, may appear in another light.

The second new function of examinations is a later development, and in some ways a characteristically, though not exclusively, English development—I mean their use to test not so much the efficiency of candidates as that of their schools. The external examination of schools and of school children, begun by the College of Preceptors in 1853, and now carried out on an immense scale by the College and by other bodies, mainly university bodies, all over the United Kingdom, had primarily for its object to distinguish between the sheep and the goats of the private schools. The examination, as thus used, was organised primarily as a technical test, good or bad, not of the taught, but of the teacher. But are not the real interests of the taught, which it was originally intended to serve, sometimes, or perhaps often, lost sight of in the process? Here, again, the difficulty of an examination is apt to be confused with its efficiency.

There is a third function of examinations, not easy to distinguish altogether from the original function of testing efficiency—I mean their function to test what is called "general culture." In dealing with this question, we find a certain amount of common agreement as to what is the best policy, combined with a powerlessness to carry out that policy in the face of our present organisation of examination and education, and our refusal in education to remember the wisdom of leaving some things the time and opportunity to "shift for themselves."

It will, I think, be generally admitted that culture is something more than the knowledge of the best that has been thought and said in the world, according to the definition of Arnold, unless knowledge is used with a far wider connotation than is possible in the examination room—something perhaps more personal and sensitive than the "enlargement" which John Henry Newman contrasts with knowledge. I shall enter into no rivalry of epigram with these great masters of style, but I think, on cross-questioning, we should find that the cultured man is the man who is sensitive and responsive over a large field of knowledge regarded as of value by the community. On cross-questioning we should again find it generally admitted that that sensitiveness and responsiveness are apt to suffer injury by the drastic concentration required for the examination syllabus; at every step the delicate feelers of the mind are paralysed by the suggestion: "I am wasting my time in going further; that won't be asked." It may be held, and I should agree, that culture is as individual a thing as conscience; that culture may be killed, that it cannot be caught, by examinations. Yet teachers who realise all this, who think examinations in their subject mischievous rather than helpful, implore the authorities to include it in every possible examination syllabus. Why? Because, under the present *régime*, a subject that is not examined in is likely to disappear speedily from our teaching curricula. That point is sufficiently illustrated by the controversy on examinations in Greek.

We have thus seen that examinations are nowadays conducted with four distinct, primary objects:—

(1) To test the efficiency of a person for the practice of his technical calling or profession.

(2) To arrange candidates in an order of merit.

(3) To test the efficiency of schools.

(4) To promote general culture, an object for which many persons regard them as totally unsuited.

I am quite aware of the complexities of the issues raised by this simple classification. A recent writer, dealing with the same problem from a different point of view, has made out a list of seventeen qualities which an examination can test, and thinks his list might be extended still further. My classification deals only with groups of such qualities, and the grouping will vary with the specific object of an examination. I think it quite possible that I should find it difficult to conciliate all my critics, and most of all those who are partial to the examinations in Class (4) of my list. I am, however, willing, as I said before, to concede that any particular examination, and any particular examining body, may have all the virtues claimed for them; but I would ask of those concerned if it is not a fact that if we took the examination-papers set at many examinations, and inspected them in detail, we should find it an impossible task, from internal evidence, to decide with what object, or with what combination of objects, those examinations are organised. Individual examiners are not asked to bear in mind, nor is it, perhaps, always desired that they should bear in mind, the careers which the examinees propose to follow; they are asked, not to examine with any particular aim in view, but to examine "in

their subject," and this, I suppose, is what is meant by the opponents of examinations when they rail against examinations for examination's sake. Thus I am inclined to think that the most ardent advocate of the examination system would be prepared to admit that the object of many examinations held nowadays is indeterminate. It can scarcely be expected, therefore, that the results will be in all cases precise.

Before we can estimate in detail the results of examinations, we must say something of their methods. Examination tests may be classified in two ways: firstly, according to what may be called their external character, under which heading we may divide them, as usual, into written examinations, oral examinations, and practical examinations; and, secondly, according to a character much less obvious, but more important. They may be divided into:—

1. Knowledge-tests (or memory-tests), which test the power of restating facts and arguments of a kind that may be learnt by rote—*e.g.*, "Describe Joule's experiments on the mechanical equivalent of heat"; "Relate the chief events in the reign of Edward I."; "Write out the 47th proposition of Euclid"; "How is the preposition 'in' used in Latin?"

2. What may be called capacity-tests, which test the power of doing something, of applying knowledge to some definite purpose, *e.g.*, the power of making a *précis* of a written document, of writing a letter or a report on a particular subject with a particular object in view, of translating from or into a foreign language, or of conversing in that language, of solving a mathematical problem, of criticising a passage from a literary work, of writing an essay on an historical or literary subject with the aid of books in a library, of diagnosing the malady of a patient, of analysing a chemical mixture or compound; and (perhaps, the highest form under the rubric) of making an original contribution to learning or science as the result of personal investigation or experiment.

In some cases the category to which a question belongs will depend on the previous preparation of the candidate. If a candidate who is asked to describe the foreign policy of Queen Elizabeth has only had access to text-books in which Elizabeth's foreign policy is treated incidentally in a more or less chronological record of events, he may show considerable capacity in separating out in his mind the threads of foreign policy from the rest, and putting the results of his thinking into clear language; if he has been in the hands of a teacher who has dwelt on the particular question, his reply may show memory or "knowledge" and nothing more. In subjects like political history or history of literature, it appears to me extraordinarily difficult to set questions in papers of the ordinary three-hours type, which shall come clearly under the heading of capacity-tests*; whereas in many subjects the questions may be either knowledge-tests or capacity-tests, and most written examination papers include questions of both types.

The classification which I have here set down, hinted at by Mark Pattison, and no doubt by earlier writers, but perhaps first clearly enunciated in a remarkable but too little-known work by Latham on "The Action of Examinations," published in 1877, obviously does not correspond to a logical dichotomy. The capacity-test of the kind used in examinations does imply knowledge, though the knowledge-test does not imply capacity beyond that of memorising and an elementary (and at times doubtful) mastery of the mother-tongue. It is sometimes said that the memory-tests set at examinations are too hard, that the knowledge, laboriously pumped into the brains of candidates under examination-pressure, escapes rapidly when that pressure has been released, and that if we were to apply the witty definition of education as what remains when we have forgotten what we have learnt, the result of examination-education is nil. It would not be wise to accept that conclusion without reserve. It is, at any rate, true that examiners do not by any means demand that candidates should know everything that they are asked; the ordinary examiner at a pass examination is content if the examinee can answer satisfactorily from one-third to one-half of the questions set. When these questions are memory-tests, the indulgence is surely justified in most cases, although there are perhaps ignorances of fact of a dangerous character to which this leniency should apply. An examiner told me recently that on the ground that a certain candidate had obtained the necessary number of marks in physiology (and I shall come to the question of marks presently), he had been allowed to pass, although he firmly believed that there was air in the left ventricle of the human heart. The examination, I may say, was not a university

* Mr. M. W. Keatinge, in his "Studies in History" (A. & C. Black, 1910, chap. viii.), makes interesting proposals to meet these difficulties.

examination. On the other hand, for some examiners printing might never have been invented, and books of reference might be as costly as they were in the Middle Ages. I shall not be accused of exaggeration when I say that a knowledge of technical terms in foreign languages is sometimes demanded by examiners which would certainly not be expected of candidates in their own language.

In dealing with capacity-tests, the question of leniency and severity takes on another aspect. A boy who can only do right five addition sums out of ten cannot add. A person who reads a thermometer accurately five times and inaccurately five times cannot read a thermometer. A person who understands nine-tenths of the words in an easy passage in a foreign language, with or without the use of a dictionary, and who is at sea in regard to the meaning as a whole, has not brought his knowledge of the language to a useful point. On the other hand, if a candidate can satisfy capacity-tests, if we are able to assert from the definite evidence of the examination room, by his obtaining not 30 or 50, but, say, 80 or 90 per cent. of the maximum marks assigned to such tests,* that he can do this kind of problem in mathematics, that he can speak this foreign language so as to make himself understood on everyday topics, that he can analyse a leading article in a daily paper so as to present its gist fairly and clearly to a person who has not read it, we need not fear that these capacities will fade away a week or a fortnight after the examination.* I firmly believe that examinations *can* tell us something definite about candidates. The question is, do they at the present moment? It is obvious that the answer will not be the same in regard to all examinations, that no general answer can be given to my question. But we shall understand its precise bearing if we deal a little more in detail with the question of numerical marks, adopted, not in all examinations, but in most pass examinations and in most competitive examinations.

The system is familiar to every one. A certain number of marks is assigned to each question set, and the maximum obtainable for a paper is the sum of these marks. The number of marks allotted to each candidate is the sum of the marks assigned to his several answers to those questions; and the ordinary working hypothesis is that the value of the performance of the candidate is proportional to the total number of marks he obtains. Putting the thing in another way, we may say that the hypothesis amounts to this, that, if we arrange candidates in the order of their performance as determined by the aggregate of marks obtained, we shall be doing them no injustice, and this order is commonly called an order of merit (though order of proficiency would perhaps be a more accurate expression).

The value of this hypothesis may be tested in two ways. We may examine the postulates on which it rests, and the results to which it leads. Take, first of all, the postulates. It implies that we have some reasonable basis for determining the relative value of different questions, *i.e.*, that a number of different examiners, regarded as equally competent, will attribute approximately the same relative value to different questions; and it implies again that the same set of examiners will attribute approximately the same values to the answers to those questions given by a particular candidate. Now, although examinations are carried out on such a gigantic scale, we have very few published data to test the validity of these postulates. In a statistical investigation by Professor Edgeworth, it appeared that there were considerable discrepancies in the marks assigned by different examiners to the answers of a set of candidates.* If this is so, how can we maintain the same standard? The result is what we might expect in the case of examinations of which the object is indeterminate, for how can we estimate the value of anything unless we know what is its precise object? If a candidate is allowed to pass by obtaining from 30 to 50 per cent. of marks on memory-tests and capacity-tests mixed in variable proportions, what does a "pass" mean? What may we say that a man who just passes an examination can do? Is not the meaning of a "pass" in itself indeterminate? Does not the standard necessarily vary from candidate to candidate as well as from year to year?

If we turn again to the results of examinations carried on on a large scale, there are indications that the results of this working hypothesis are not more satisfactory than its postulates. Examiners themselves are often heard to say, "This man is better than his marks, this man

* *Cf.* the evidence given by Professor Lippmann of Paris at the *Enquête sur l'Enseignement Secondaire*, conducted by the Chamber of Deputies in 1899, Procès-verbaux, vol. 2, p. 35.

* "The Element of Chance in Competitive Examinations," *Journal of the Statistical Society*, vol. 51, p. 599 and vol. 53 p. 644

is worse than his marks," although perfect freedom may be left to them to assign marks so as to correspond to resultant merit. And if we inspect published statistics of examinations for which a large number of candidates present themselves, and in which it would be reasonable to expect that approximately the same number would attain a pass standard in consecutive years, they show that there may be the most extraordinary variations in the percentage of passes in the same subject. Those variations, I think anyone acquainted with the inner working of our examination system will agree with me in saying, cannot be regarded as due to the carelessness of individual examiners, for, in the first place, examiners take a great deal of pains with their work, and, in the second place, carelessness may tell as much in favour of a particular candidate as against him. I do not think that it is at present possible without further scientific investigation on a considerable scale, to state what are the precise facts of the case, or the precise causes of these variations. They may be due to defects in our system of marking; they may be due to real variations in the quality of candidates, of which the causes are unknown and which it would be important to discover. I want to strengthen my plea for investigation by quoting a witness whom I might have expected to find against me. If there is one subject in which accurate marking and community of standard would appear to be most easily obtainable, it is mathematics; and it seems probable that the whole system of marking by numbers is derived from the marking of mathematical papers. Nevertheless, Professor Bryan,* a distinguished mathematician and a high authority on the subject, regards some of the troubles to which I have referred as due to "fetish-worship" of the maximum mark, and suggests that we should assign certain marks to correct answers of average quality, and then mark up to any maximum we please to reward exceptional proficiency shown on any part of a paper. In this way, he thinks, candidates would no longer feel the inducement to "scramble for marks by scribbling scrappy attempts." Other authorities have suggested different ways of dealing with these difficulties, but it is safe to say that there is no agreement, and that different examiners employ very different methods. The α, β, γ, δ, or Oxford, system is another form of numerical marking in which the total number of marks allotted is low,* and in which, if I am rightly informed, the examiners as a rule attempt to obtain their resultant impression of a paper as a whole directly, instead of by the addition of marks assigned to individual questions. Here, again, it would require investigation to decide whether this system is or is not more reliable than the other. In any case, in determining a man's pass or class, you do not escape entirely from the difficulties involved in the addition of marks. Moreover, the Greek letter system appears, so far as I can see, to be inapplicable to a competitive examination on a large scale in which candidates present themselves in a number of subjects.

The assignment of marks in practical examinations is probably an easier matter than in written, for the reason that most practical examinations, though not all, are capacity-tests rather than memory-tests, and it is easier to say whether a candidate can or cannot do what is required of him.

Of all kinds of examinations, that which may be the most valuable, and that which presents the most difficulties, is the *viva-voce* examination. Largely used abroad, it is used comparatively little in this country, because our boys and girls are not taught to speak and to think at the same time at the age when children speak confidently and easily, and hence in the presence of the examiner the candidate is often paralysed by nervousness, for which it is difficult, or impossible, to make the proper allowance. He may be reduced to silence or nonsense. A candidate in Materia Medica in a northern university, who was unable to distinguish the taste or the smell of the sample of cod liver oil that he held in his hand, on being asked, "Where does cod liver oil come from?" replied, "The whale."

Nevertheless, the *viva-voce* examination has the immense advantage of allowing a reasonable examiner to ask a candidate not paralysed by nerves what portion of a subject he has specially studied, and to cross-examine him considerately in that. The negative evidence that a candidate says nothing in regard to a particular printed question does not carry one very far. The frank "I don't know" of a candidate, his power of distinguishing what he does know from what he does not, will, with an examiner capable of judging men, count very greatly in favour of a candidate whose knowledge of the parts of the

* Articles on "Examinations," by Professor G. H. Bryan, Sc.D., F.R.S., published in the *School World* for May and June, 1910.

* By adding the signs + or − to the Greek letters, the number of symbols used is, as a rule, increased to ten or more.

subjects that he thinks he knows is sound. But a *viva-voce* examination, if it is to be valuable, must not be hurried, and hence it is an expensive form of examination. It has again the defects of its qualities. The idiosyncrasies of examiner and candidate may come into conflict in regard to matters which have nothing to do with the particular examination test. To combat this defect, it is generally recognised that *viva-voce* examinations should, if practicable, be conducted by a board of examiners rather than by a single examiner.

We have in the *viva-voce* examination a sense of reality that is apt to become somewhat thin in the written examination. If an examiner knows that he has to decide, face to face with a candidate, not whether he attains a particular standard in a particular subject, but whether he has the knowledge and capacity to do a particular job or pursue a particular career, he will feel much more able to come to a decision than after he has merely seen the candidate's written papers. Would any sensible person, in business, in war, or in administration, free to choose his own subordinates in carrying out an important piece of work, dream of doing so without an interview, if he could help it? On the whole, it seems to me that our examination system would be more efficient if larger use were made of the oral method than is made at present. But there are administrative difficulties in conducting them not to be under-estimated.

Before leaving the question of examination methods to enquire further into the effects of examinations on the candidates, I want to throw out one suggestion. I believe that we should effect a quiet revolution in pass examinations, but a revolution, if we would systematically ask ourselves in regard to each examination, what does it prove that all successful candidates can do? What are they certainly fit to do? Such a question would put capacity-tests and memory-tests, I believe, in their right places, and the examination would become once more, as in its origin, what the mathematicians call a directed quantity.

And now for the effect of examinations on candidates. If we take a large cold thermometer, as accurate an instrument as you please, and plunge it into a relatively small quantity of warm water, the reading of the thermometer will not tell us directly what the temperature of the water was before we tried to measure it. In the same way, even the most admirably organised and designed examination will generally exercise a very considerable disturbing influence on the previous education of the candidate that it is designed to test, and on the candidate himself during the examination. In the case of the thermometer, we can correct our original reading by making the necessary allowance; in the case of the examination candidate, what correction can we possibly make?

How, if we cannot calculate them precisely, shall we reduce the bad influences and magnify the good influences of examinations as far as possible? It is a grave problem, and we shall find considerable disagreement in determining what features of examinations belong to one category, and what to the other. Let us, for the moment, consider the influence of the examination on the candidate while it is being actually carried on. There can be no doubt that examinations prolonged over several days, for from four to six hours a day or more, involve a considerable physical strain on the candidates, and the sample of the knowledge and capacity which the examination affords can hardly be regarded as an average sample. With some candidates the excitement and strain make them do better than they otherwise would do; with others the reverse is the case. Ought we to try to reduce that strain? A good many, I fear, would not assent. It has been said, and not infrequently said, that if a candidate fails under the strain, he is lacking in some of those qualities which go to make a successful man, and that though failure in the particular examination does not mean (as the public might, and often do, think) that he has not the intellectual attainments of those who pass, yet that no harm is done. It seems probable—one cannot go further than that—that failure in examinations owing to ill-health takes place more frequently in the case of women candidates than men, and the question of women candidates certainly needs separate investigation; but in the absence of adequate statistical and medical inquiry, the whole hygiene of the examination-room remains obscure. Much more important, in the long run, than the immediate influence of the examination-room on the candidate is the influence of his preparation for the examination during the long years of school and university life. That is a subject too complex and important for me to do more than mention; I would only suggest two things—firstly, that in some subjects and with some candidates, the influence of examinations may be good and not bad; and secondly, that instead of encouraging by

means of examination subjects ill-suited for examination tests, we might try to protect them from those tests. I do not say that it is easy, but I think it not impossible.

Let me take the subject of history, which, of all subjects that come under the heading of "culture" subjects rather than "bread-and-butter" subjects, is the most important to the ordinary citizen. Would it not be possible to reduce school examinations in history to a minimum by allowing those who had attended a history class in a secondary school, to the satisfaction of a duly-qualified teacher, to be exempted from any kind of school-leaving examination in history? Of course, it will be said that the standards of different teachers would be different, but are we not inclined to sacrifice on the altar of equality the very efficiency of the teaching that examinations are intended to test? I remember, in a French Lycée, hearing a lecture on Napoleon's *coup d'état* of the 18th of Brumaire given to a class of science boys who were not to be examined in the subject. The lecture was full of warmth and colour, every boy was interested, every boy was listening, and I contrast that with the painful dictation of slow sentences reproducible in the examination-room that I have heard in some English secondary schools. I do not mean that all French teaching of history is good, and that all English teaching of history is indifferent. I believe there is no subject in which more rapid progress is being made in this country. Might not the examining bodies help the history teachers in other and better ways than by inserting history in all their syllabuses, as the teachers seem to desire?

In dealing with this matter, I would suggest that it is as impossible to make certain that every boy or girl who leaves school has an adequate knowledge of history, has a real beginning of historical culture, as it would be to make sure that every boy or girl who leaves school has musical culture or artistic culture. Supposing you do make sure by examinations that the school-leaving certificate implies a certain knowledge of the facts of history, what then? A boy coming out of the examination-room once said to me: "I am never quite sure whether the date of Magna Carta was 1215 and Waterloo 1815, or whether it was the other way about, but I think I have got it right this time." A boy of that kind, even with the more difficult questions set nowadays, might absorb history, but he would never assimilate it, and instead of trying to force him to be cultured in a subject where culture is impossible for him, would it not be much better to recognise his insensitiveness on the historical side, and push him in some other direction? What I have said of history, applies even more strongly to literature. If we could only make up our minds to require real efficiency in one or two subjects, and give our boys and girls the opportunity of learning other subjects, without forcing them mechanically to do so, would not our education become much more effective in the end? Are we not led by the will-o'-the-wisp of general culture into a mire of general inefficiency? I asked a friend of mine who is an experienced examiner what it would be safe to assert of the powers of a student who could just succeed in obtaining pass marks at a pass examination in several subjects. His reply was: "I think you could say that he could pass the examination at the time that he passed it." I went further. "Would it be safe to say that he had any useful knowledge of the subjects of the examination—that he would be fit for any career?" The answer was clearly: "No, you could say none of these things. When you have said that he has passed the examination, you have said all that can be said."

If we turn from pass to competitive examinations, we find that they involve all the same problems, and fresh ones to boot. Here it is well recognised that difficulty may be used as the means, not of testing proficiency in subjects that will be required in later life, but to distinguish different candidates in regard to what is called their "general ability." The great choice of subjects permitted by the regulations for the Open Competitive Examination for the Home and Indian Civil Services sufficiently illustrates this point. That particular examination is one of the very greatest importance. Is it really fulfilling its purpose in the best way possible? Professor Browne, of Cambridge, in giving evidence before Lord Reay's Committee on Oriental Studies (Minutes of Evidence, page 62), said that, contrary to his expectation, the men selected by the method devised by Lord Cromer, in connection with the Egyptian Services, learnt Arabic more quickly than the men selected by open competition for the Indian Civil Service. I believe Lord Cromer intends to say something later on the methods that he used. I do not say that Professor Browne's isolated observation proves anything conclusive, but it is significant, and points to inquiry.

The tremendous severity of the Civil Service examinations has been regarded as imposing a

sufficient test of the character and of the physical strength required for arduous public service. But do we know at the present moment whether the game is worth the candle? A letter from a candidate who wrote over the somewhat unfortunate signature "Presque passé" in the *Times* of last summer, reminds one uncomfortably of the sad picture of overworked Indian examination students drawn about the same time by Mr. Valentine Chirol in his articles on Indian unrest. Is it not possible to test "general ability," and to separate the ablest candidates by methods involving less strain both on the successful and the unsuccessful candidates? The experimental psychologists and statisticians, working on lines suggested by the late Sir Francis Galton, hold out hopes in this direction, but one must confess that they are still somewhat remote. Would it be possible, without reintroducing the unspeakable evils of jobbery, to follow the lines laid down by Lord Cromer in the Egyptian Civil Service, and by Lord Selborne in choosing candidates for the Navy? These are questions again for inquiry.

Conclusion.

How should such inquiry be carried out? I do not think that any other body than a Royal Commission would carry with it the necessary weight. I believe the Commission should be a small one, presided over by a statesman with great experience of affairs, and that there should be no attempt to achieve the impossible by including in it representatives of all parties concerned. If, following the example set in Professor Sadler's Moral Education inquiry, and in the recent report of the Consultative Committee of the Board of Education on Evening Schools, the evidence taken was published, not in the unreadable and unwieldy form of question and answer, but in the form of statements on particular topics summarised by the witnesses from shorthand notes, after their examination by the Commission, every person and every interest would have a fair say; and the members of the Commission themselves would not have any undue advantage in giving their own summary of the evidence, and their own conclusions. But such a Commission, to do all that it should do, would need to be far more than a Commission of Inquiry in the ordinary sense; it would need to be a Commission of Investigation. It should have the power to appoint and to pay committees of experts in different subjects, who would carry out investigation under its direction. Take the questions of standard and of marking. Those questions it is quite impossible to investigate without having a large number of candidates' answers lithographed and sent to be marked to different examiners, first without directions at all, and secondly with directions in regard to the stress to be laid on particular points regarded as of especial importance. Nor would the expert in his subject alone be necessary; the assistance of the statistician would have to be called in at each step. I believe that in this way we might be able to make an examination standard that would mean something very different from what it means now, that would be reasonably constant from year to year, and that would substitute the fairness of reasoned judgment for the fairness of chance, in the case of far more candidates near the border line. That would be one of the matters for the Commission to investigate. If it were to appoint sub-committees in a half dozen, or a dozen, subjects of examination, the results of the inquiry would probably throw sufficient light on the subjects which it was not possible to touch.

A second question for investigation is the hygiene of the examination-room. How far are we making fair demands on our students in the examinations? How far do they exceed, from the point of view of strain, what it is reasonable to demand?

A third point for inquiry, and that the most difficult, is the influence of examinations, good and bad, on education as a whole. I would only suggest here that different classes of candidates and different subjects require different treatment, and that it should be the object of the Commission to find some way of protecting from examination those school subjects which are unsuited to them, and in which examinations dig up the roots of the plants which we wish to grow.*

Fourthly, the Commission would inquire how far our different sets of competitive examinations select the persons most fitted for the posts which they are intended to occupy.

In this connection, the Commission would, no doubt, consider the question of associating with the experts in their particular subjects administrators with experience of the services for which candidates were being chosen.

I have selected four large topics for inquiry:

* It is understood that the Consultative Committee of the Board of Education are considering the question of school-leaving examinations, but they have not yet issued any report on the subject.

(1) the question of standards and marking, with which is closely connected the question of the precise object of the examination concerned; (2) the hygiene and psychology of examinations; (3) the influences of examinations, good and bad, on previous training; (4) competitive examinations for the Services. But these topics would subdivide, and others would suggest themselves for investigation. A Commission with a suitable reference would find no lack of useful work to do. I suggest as a reference: "To investigate and report upon the methods and efficiency for their purpose of examinations carried on by Government Departments and other public bodies in the United Kingdom; to inquire into the influences of examinations on the previous education of candidates; and to suggest such changes as may seem desirable."

The investigations of such a Commission would be of immense assistance both to the teaching and to the examining bodies of this country. I have tried to obtain figures showing the magnitude of our examination operations. Those figures are still far from complete, but I have official statistics, supplied to me by the authorities concerned, that show that in the year ending September 30th, 1910, out of 146,741 candidates at public examinations in the United Kingdom, 71,114 failed. I have little doubt that when my figures are complete—and I hope I may be permitted to publish them later—the total entries will approach 200,000, and the failures 100,000. Does there not seem to be something very wrong in the relations of our examination with our education for nearly half the persons to be judged unfit to pass the test for which they present themselves? How far is this great percentage of failures due to a low average of intelligence or industry, how far to the fault of the teachers, or the fault of the examiners, or to want of co-ordination between teacher and examiner? Conscientious in their details, have not our examinations been largely at the mercy of hazard in regard to principles?

Lord Rosebery, speaking in 1907 as Chancellor of the University of London,* urged strongly that examiners needed training no less than teachers. He also suggested the need for investigation. For such teaching as Lord Rosebery desires I doubt if any common basis of doctrine at present exists. It must be created.

There is one serious obstacle to change. The examiner and the organiser of examinations are often so weary of their ungrateful tasks that for them the day's work is enough; they become sceptical of improvement, reconciled to evils that they have come to regard as unavoidable evils. But the issues are too grave to be overlooked, and the investigation and reform that I have ventured to demand are a matter of national necessity.

* At the opening of the London Day Training College; see the *Times* of November 4th, 1907.

DISCUSSION.

The CHAIRMAN, in opening the discussion, read the following letter from Professor M. E. Sadler:—

"To my very great regret I shall be prevented from coming to hear Mr. Hartog's paper on Examinations at the Society of Arts next Wednesday evening, owing to an engagement elsewhere which I cannot alter.

"No recent educational event is likely to prove of greater importance than the reading of Mr. Hartog's paper and the discussion upon it. No one in England, or indeed in any part of the world, has given more thought to the problems involved in our examination system than Mr. Hartog, and his acute and practical mind will guide us to a wise handling of the urgent questions which are now beginning to press on us through the excessive development of the examination system.

"Had it been possible for me to attend the meeting, I should have strongly supported the proposal that a small Royal Commission, with groups of scientific assessors, should be appointed to inquire into the question. The time has come for probing the principles of the system, which affects in a hundred ways the intellectual life of the country and its administrative efficiency."

Proceeding, the CHAIRMAN said:—I am sure that you will all agree with me when I say that we owe a deep debt of gratitude to Mr. Hartog for the very interesting paper to which we have just listened. It is a paper which stimulates thought, and, let me add, there are few subjects more deserving of thought at present than that to which Mr. Hartog has drawn our attention. We seem to be about to enter a period during which, whether for good or evil, the State, either in its imperial or municipal capacity, is likely to develop great activity in the performance of a variety of new functions. How are the large additional number of agents whose services will thus be required to be recruited? The results which will be obtained by the new departure now being made will, in a great measure, depend upon the answer which is given to this question. It is perhaps an exaggeration to say with Pope that "Whate'er is best administered is best," but it is certainly true that a good system may be marred by maladministration, whilst the defects of a faulty system may be greatly mitigated if the administration is efficient.

There are, so far as I know, only three methods under which public functionaries can be appointed.

These are election, selection or nomination—the two words are, for the purposes of my present argument, synonymous—and competition, either open or restricted.

I need say but little of the elective method. Its advantages are mainly political rather than administrative. An eminent French economist, M. Leroy Beaulieu, has said:—"According to democratic theory, popular election will always secure the most capable individuals; but this is a curiously mistaken idea, and is quite unsupported by experience."

The Poor Law Commission, over which Lord George Hamilton recently presided, took the same view. "The method of popular election," the Commissioners reported, "is not one which is adapted to get the best administration. The Commission believe that there is a better chance of good administration if the members are appointed than if it is left to the chance of election." I will not, however, dwell any further on this branch of the subject, as it touches the fringe of political issues, which I am anxious to avoid. I will only, therefore, say in general terms, that one, and perhaps not the least important of the questions which the democracy of this country will have to face in the near future, is how to combine administrative efficiency with an adequate amount of popular control. I have often, in the course of my Eastern experience, had to deal with a very similar problem, and I generally found that the question practically resolved itself into this—How much efficiency is it justifiable to sacrifice on the altar of self-government? I came to the conclusion, under the special circumstances with which I had to deal, that it was impossible to generalise on this subject, and that each separate issue, as it arose, had to be decided on its own merits.

Turning to the other alternatives, viz., selection or competition, it may readily be admitted that competition, which is the prevailing system now, has its defects, but before condemning it, it is worth while to glance back at the system which it supplanted. I am one of the band, not now very numerous, who can speak with some personal experience of the pre-competition days, and, as illustrations of the working of the then existing system, I may perhaps be pardoned if I relate a few biographical details. Some fifty-six years ago, being then a boy of fourteen, I was admitted into the Royal Military Academy at Woolwich, with a view to eventually becoming an officer in the Artillery or Engineers. At that time there was a sort of sham entrance-examination, but I never heard of any boy who had been nominated by the Master-General of the Ordnance being rejected. Lord Hardinge, the grandfather of the present Viceroy of India, who was a friend of my family, gave me my nomination. On presenting myself at Woolwich for medical examination, I was very rightly rejected for short sight. I returned to London and told my mother, who was my only surviving parent. She acted with promptitude. She instantly rang the bell, ordered her carriage and went to the Horse Guards to see Lord Raglan, who had succeeded to Lord Hardinge's place, and who was another friend of my family. The result was that next day I returned to Woolwich with a letter addressed by Lord Raglan to the medical officer, asking him to "reconsider the matter." I was, of course, admitted. Exactly the same thing happened at the same time to another lad who was at first rejected on the ground that he had a serious impediment in his speech, but whose case was subsequently, under pressure, "reconsidered." This sort of thing could not happen now. The practical working of the system may, however, best be illustrated by an anecdote which is related of Lord Melbourne. A friend of his who occupied a high position and who disposed of a good deal of patronage, said to him:—"I do not in the least mind confessing that if I had to deal with two candidates, one of whom was the son of a friend or relation of mine, and the other a stranger, I should, *ceteris paribus*, give the appointment to the son of my friend or relation." To which Lord Melbourne drily replied, "So should I, but *ceteris paribus* be damned." In fact, at that time the principle laid down by George III. had only been but slightly modified. That monarch is believed to have said that any one was fit to occupy any place he could manage to get.

Well, ladies and gentlemen, as a result, partly of the attention called to military matters by reason of the administrative breakdown during the Crimean War, and partly of the extraordinary call for officers occasioned by the Indian Mutiny, the nomination system, in so far as appointments to the Artillery and Engineers was concerned, was swept away and the competitive system introduced. It started under rather bad auspices. I remember that the first notice issued by the War Office was rather unfortunately worded. They called for "persons" to compete. The result was that all the young men who responded to this call were instantly dubbed "persons," and commanding officers showed a marked preference for those who had entered under the old system and who had enjoyed the more exalted title of "gentlemen cadets." I was at that time an ardent young Liberal, as I claim to be an old Liberal now, although my right to that designation may perhaps not be recognised by mere party politicians, and I was warmly in favour of reform. As a matter of fact, the gloomy predictions of the anti-reformers were falsified by the event. The social class from which the officers who entered the Army were drawn, was just the same after as it had been before the change of systems, whilst there can be no doubt that a distinct improvement was effected, both in intellectual standard and professional capacity.

I mention these points mainly in order to show that the competitive system, whatever may be its defects, is greatly superior to that which it superseded, and in order to warn the advocates of reform

that they must beware lest a door be opened which may lead to a revival, perhaps in a somewhat different form, of the abuses of the past.

And now let me make a few remarks on the competitive system considered on its own merits. I think the best thing I can do is to deal with facts which have come within my personal experience, and, as you are probably aware, my personal experience has been gained more in the outlying portions of the Empire than at home. I have seen a good deal of the work performed by the young men who are turned out by our universities and military colleges. I have met them on the banks of the Ganges, the Indus, the Irrawaddy, and the Nile. And I have also had some rather exceptional opportunities of comparing their aptitudes with those displayed by their Continental rivals and competitors. From one point of view the comparison is disappointing. I have often had it said to me by heads of departments in Egypt, themselves Englishmen, that the young Frenchman or German came to them crammed to the muzzle with an amount of preliminary knowledge greater than that possessed by the young Englishman. The explanation is, I think, that until of recent years sufficient attention has not been paid in this country to technical education; that is unquestionably a defect, more especially at a time when there is a tendency to specialise every branch of learning, but it is a defect which I hope and believe is in process of being remedied. But if we look at education not merely as a means for storing the mind with knowledge, but also as an instrument for developing the character, the situations are reversed. The youth in whom the need of individual effort and the sense of personal responsibility have been nurtured in one of our public schools or colleges, becomes almost unconsciously *capax imperii*. He is no automaton. In the free atmosphere in which his boyhood and youth are passed, he learns a number of lessons which stand him in good stead in after life as a member of an Imperial race. More especially, he learns not only to think, but, which is much more important, to act for himself—in a word, to govern, and to govern generally with firmness, justice and wisdom. From this point of view our system of making appointments, which is generally, though not exclusively, the result of competition, may, I think, in spite of some defects, be said generally to have produced satisfactory results. A very high authority on Indian affairs, Mr. Valentine Chirol, recently wrote:—"To the Indian civilian belongs the credit of almost every measure passed during the last fifty years for the benefit of the Indian masses, and passed frequently in the teeth of vehement opposition from the Indian politician." I think you will agree with me that this is very high praise. The system has thus turned out a number of young men, who, as the agents of a nation whose very existence depends upon the execution of a sane Imperial policy, are not only of incomparable merit, but, I do not hesitate to add, are also the envy and admiration of the whole civilised world. Whatever changes may in the future be made in our educational system, I most earnestly trust that no steps will be taken which may tend, in any degree, to weaken that sense of independence in thought and action which should constitute the basis of character to the individuals who are the units of any self-governing community.

In spite, however, of this success, I think we may well ask ourselves, after the experience of half a century of the working of the competitive system, whether it is not capable of improvement. The question is certainly worthy of consideration. Remember that the principle of selection, if only it can be properly carried out, possesses merits superior to those of competition. The former may, or ought to result in the creation of leaders of men. It should enable us to acquire for the public service the aristocracy, in the proper and original sense of the term, that is to say, not the aristocracy of birth, but that of intellect and of character. The latter tends rather to produce a dull level of mediocrity. Most educated Englishmen have recently been reading the history, written by a very distinguished contemporary statesman of one of his illustrious predecessors—I mean Lord Rosebery's history of the early life of Chatham. Now, what was it that enabled Lord Chatham to revive British spirit when it had sunk to a very low ebb, to march to victory on the banks of the St. Lawrence and the Ganges, and to found the British Empire? I say that it was the adoption of the principle of selection, sparingly, indeed, but very skilfully employed. I notice with pleasure that of late years there has been a tendency, notably in the military, naval and diplomatic services, to adopt this principle in dealing with all the later stages of the careers of public servants more thoroughly than was formerly the case. I trust that this movement, far from being arrested, will be pushed still further. I could name numberless instances, especially in the military service, in which the dead weight of rigid regulations, based generally on the claims of seniority, have acted detrimentally to the public interests.

The case of first appointments presents naturally far greater difficulties, for, *ex hypothesi*, there can in these cases be no record of past services on which to rely, and moreover, here, and indeed in any application of the principle of selection, we are at once met with the awkward question, *Quis custodiet ipsos custodes?* Who is to select the selectors?

In connection with this subject, there is one point in respect of which I cannot help thinking that a good deal of misapprehension exists. It is not unfrequently thought that Ministers and others in whose hands the bestowal of patronage is vested, would rather welcome an accession to their powers in the matter of making first appointments. I believe this view to be wholly erroneous. My experience has led me to the conclusion that those who exercise patronage are also those who most of all delight in being fettered by regulations

which relieve them of a very irksome and onerous duty, in the exercise of which they are certain to incur a great deal of misrepresentation and abuse, and to receive very little gratitude. It is, in fact, true that the wider is the discretion left to a Minister the more fully will he be exposed to the full blast of social, and also—which is perhaps even more hurtful—of Parliamentary pressure, to make his selections on grounds other than those of merit. Moreover, unless he be an exceptionally strong man, it is well-nigh certain that he will at times succumb to this pressure. More than this, it has to be remembered that neither the action of Parliament itself, in its collective capacity, nor the power exercised by the press, however honest in intention, affords any adequate guarantees either against deliberate jobbing, or what is perhaps a greater danger, against unintentional negligence. The truth is that, save in a very few exceptional cases, the number of persons who can speak with impartiality and full knowledge of the merits of a candidate, whether for promotion and still more for first appointment, is very limited, and, moreover, it is not unfrequently difficult to obtain a frank expression of their opinions. I do not suppose, therefore, that anyone, however fully he may recognise the defects of the competitive system, would be prepared to advocate a return to the principle of uncontrolled selection.

Let me again fall back on my personal experience, and explain how, in one special instance, to which Mr. Hartog has alluded, I solved the difficulty myself. Some few years ago it became necessary to create a Soudanese civil service. In the first instance the appointments were practically made by myself. I found it a very difficult task. I used to receive hundreds of letters from the friends or relations of candidates. Of these about 90 per cent. found their way into the waste-paper basket. I took an enormous deal of trouble to select the best men. Indeed, I may remark incidentally that whatever success has attended the administration of Egypt during the last thirty years has been mainly due to the great care which was taken both in selecting and in promoting officials. Generally speaking, the method adopted in the first instance in the Soudan for making first appointments worked fairly well. Nevertheless, I felt that, apart from the great trouble and responsibility it imposed on myself, the system, or perhaps I should rather say, the absence of system, was very unsatisfactory. In the first place, I never could feel sure that the merits of many young men perhaps more deserving than those who were actually appointed had not been overlooked. In the second place, although I felt quite certain that I should not job, I felt almost equally certain that, sooner or later, I should be accused of jobbing, and the accusation would in itself have done harm, inasmuch as it would have shaken public confidence. On the other hand, I was not prepared to resort to open competition, as I was convinced that many of the qualities most required for a Soudanese civil servant could not be tested by a competitive examination. Eventually a system was adopted under which the duty of selecting candidates who are all taken from the universities was, under conditions which I need not describe in detail, conferred on a board of highly-qualified officials, who were left quite free to act as they thought best in the public interests. The system produced good results, but I do not at all say that on that account it is suitable for general adoption in this country. There are alternatives on which I need not dwell. My present object is merely to draw attention to the subject, and to indicate the advisability of considering whether it is not possible to adopt measures which will on the one hand admit of some independent control being exercised over State authorities, and more especially local authorities in cases where the competitive system, properly so-called, is not applied, and which will, on the other hand, tend to remedy, or at all events to mitigate the acknowledged defects in the competitive system itself. The test supplied by that system, though in some respects valuable, is purely intellectual, and, indeed, as at present applied, it may be doubted, more especially after the evidence adduced by Mr. Hartog, whether, even as an intellectual test, it always succeeds in attaining its object. Time does not permit me to dwell on the details; I will therefore only say that in laying down the conditions under which a competitive examination is to be conducted, the most important points to be considered are, first, how are the examiners to be appointed, and, secondly, on what principles should they proceed in awarding marks.

For the rest, I should like to point out that the Order in Council of 1871 contemplates the possibility of a departure from strict rules in certain cases, but such a departure can only be made with the consent of the Civil Service Commissioners. I believe I am correct in saying that this provision has generally been allowed to remain almost a dead letter. It is in the development of this idea that, for my own part, I should be inclined to look for reform. In any case, I hold a strong opinion that if anything is to be done in this direction, Parliamentary politicians should be rigorously excluded from participation in any boards or commissions which may have the disposal of patronage.

Ladies and gentlemen, I fear I have detained you too long. I trust, however, that this discussion will lead to the matter on which Mr. Hartog has dwelt being considered by others more competent than myself to deal with them.

The idea of appointing a Royal Commission to examine into the whole subject is certainly one which commends itself to me.

[NOTE.—The remaining portion of the discussion, which, in consequence of the threatened strike in the printing trade, has been unavoidably held over this week, will be published in the next issue of the *Journal*.—ED.]

CORRESPONDENCE.

THE INVENTION OF THE PHOTOGRAPHIC LANTERN SLIDE.

The communication, published in last week's *Journal*, from Professor Simon Gage on the early history of photographic lantern slides is of genuine interest, and appeals to all who have made any study of photographic history. Professor Gage has proved beyond all reasonable doubt that the invention is an American one, and he is to be congratulated on the result of his researches.

If any further confirmation was needed, I might add that a little while ago Mr. W. Brooks, who is probably the oldest living photographer, since he is now about eighty years of age, and began his career as a professional photographer in 1849, told me that the first photographic transparencies he could remember were made on albumen, and were shown at the Polytechnic in Regent-street. He added that they were rather dense, as would very likely be the case.

With regard to the application of collodion to the production of lantern slides, a claim may be put in for a photographer on this side of the Atlantic. Professor Gage, in his correspondence with myself, referred to Dr. Neuhauss's "Lehrbuch der Projektion," in which the author says that Dancer, of Manchester, was the first to apply photography to the production of lantern slides. This statement, so far as this country is concerned, is confirmed in the obituary notice of Dancer, which appeared in the "Proceedings of the Manchester Literary and Philosophical Society" (Fourth Series, Vol. I., p. 149). This is merely to the effect that he was the first to suggest the application of photography to the magic lantern, but no date is given. Dancer, who was born in 1812 and died in 1887, was in his time an optician of considerable repute in Manchester. He appears, without much doubt, to have been the inventor of microphotographs, that is to say, photographs on a very small scale used for magnification in a microscope. These scientific curiosities cannot be said to be of any practical value, and, though they were at one time rather popular, I do not imagine that many are now made. The date of the invention is 1853.

Samuel Highley, in a paper read here in 1863, speaks of photographic lantern slides having been constantly made by amateurs, and states that Negretti and Zambra were the first to produce slides commercially. I am also informed by Mr. Freshwater, a member of the firm of Newton & Co., that his firm produced photographic lantern slides at a very early date.

It may, perhaps, never be possible to say whether Dr. Briggs or Mr. Dancer was the first to make lantern slides on collodion (a process which, of course, was for long the usual method of their production), and perhaps it does not now very much matter. As soon as collodion came into use, its application to the production of diapositives was fairly obvious. It seems evident that the invention was made independently by the two men. What is really interesting to know, and this Professor Gage has shown us, is that the invention of the photographic lantern slide is unquestionably due to Langenheim, of Philadelphia, and that the date was 1850. H. T. WOOD.

OBITUARY.

The Rt. Hon. Sir CHARLES WENTWORTH DILKE, Bart., M.P.—The death of Sir Charles Wentworth Dilke, which took place on the 26th inst., at the age of sixty-seven, removes from the list of the Society's members a name which has figured there continuously for sixty-six years. In 1845 Charles Wentworth Dilke, father of the late baronet joined the Society, and four years later *his* father, likewise Charles Wentworth Dilke, was also elected a member. In 1857 the late baronet, then a boy of thirteen, was elected a life member of the Society, and in 1859, his younger brother, Ashton W. Dilke, also became a life member, so that at one period there were on the Society's list no fewer than four Dilkes—three of them Charles Wentworth—all giving as their address 76, Sloane-street.

The second Charles Wentworth Dilke took a very deep interest in the work of the Society. With one short interval, he served from 1846 to 1863 on the Council, of which in 1857-8 he was Chairman. He was a member of the Society's Committee for promoting the Great Exhibition of 1851, and it was in recognition of his valuable services in connection with this and the International Exhibition of 1862 (which was also promoted by the Society of Arts) that a baronetcy was conferred upon him.

From his early years the late baronet was in the habit of attending the meetings of the Society, so much so that a short time ago he said it almost seemed to him that he had been born in the building. He served on the Council in 1869 and 1870, and was a member of the Colonial Section Committee from 1896 to the time of his death. He read two admirable papers before this Section, the first in 1897 on "The Progress of the British Colonial Empire during the Sixty Years of Her Majesty's Reign," the second in 1900 on "The Century in our Colonies," for each of which he received a silver medal; and he also took the chair on several occasions at meetings of the Society.

Of Sir Charles Dilke's political career so much has been written during the last few days that it is unnecessary to do more than recall it in the briefest terms here. Educated privately in boyhood he became a scholar of Trinity Hall, Cambridge, where, after acting twice as President of the Union, he graduated as "senior legalist," or head of the Law Tripos. Soon after leaving college he made a tour round the world, and published the results of his studies and observations in a work

entitled "Greater Britain: A Record of Travel in English-speaking Countries during 1866 and 1867." The book achieved an instant and great success, which no doubt largely assisted in procuring his election to Parliament in 1868 as representative of the new borough of Chelsea. He soon made his mark in the House of Commons, and was looked upon as one of the coming men of the Radical Party. It was on his initiative that the municipal franchise was conferred on women; and in 1878 "Dilke's Act," as it was popularly termed, extended the hours of polling at Parliamentary elections in London. In 1882 he was appointed Under-Secretary to the Foreign Office, and at the end of that year he was promoted to a seat in the Cabinet as President of the Local Government Board. In 1885 the Gladstone Ministry was defeated on the Budget, and Sir Charles never held office again. For seven years he was absent from Parliament, but in 1892 he was again returned as M.P. for the Forest of Dean Division of Gloucestershire, a seat which he retained till his death.

In later years he devoted a great deal of attention to questions of foreign policy and imperial defence. He was also an acknowledged authority on labour questions in general, and some of the recommendations of the Select Committee on Income-Tax, of which he was chairman in 1906, have been embodied in financial legislation.

GENERAL NOTES.

Banking in 1910.—In spite of two General Elections and a postponed Budget, the year 1910 has proved by no means unfavourable to bankers. This, as Sir Edward Holden stated at the annual general meeting of the London City and Midland Bank, was due to the fact that 1910 was a record year for almost every country. International trade exceeded the previous high-water mark of 1907: in our own case, imports and exports, amounting together to 1212 millions, exceeded those of 1909 by about 10 per cent., and those of 1907 by about 4 per cent. In consequence of this general prosperity the profits of the London City & Midland in 1910 would have been record ones but for the fact that surplus profits had been used to write down securities. As it is, the profits amounted to the satisfactory sum of £801,781. Equally favourable are the results shown by the London County & Westminster Bank on the first year's working since the amalgamation of the London & Westminster and London & County Banks. With increased business they have opened fourteen new branches during the year, and, in spite of political disturbances, they are able to declare a dividend of 20 per cent.

Massachusetts and a Nine-hour Day.—It is only recently that a fifty-six hour law came into operation in Massachusetts, and already an agitation has been started for a nine-hours day. A Bill for the reduction of hours to that basis has been determined on by the textile councils of New Bedford and Fall River, as one of the results of a conference. The employers will oppose the change, but their resistance is not likely to be successful, for the State elections have demonstrated the great strength of the labour vote, and that is expected to go "solid" for the Bill.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

February 8.—Captain A. J. N. Tremearne, B.A., D.Anth., "Some Nigerian Head-Hunters." Colonel Sir John Smith Young, C.V.O., will preside.

February 15.—George A. Stephen, "Modern Machine Book-binding." John Murray, J.P., D.L., F.S.A., will preside.

February 22.—Professor J. Wertheimer, B.Sc., B.A., "Water-Finders."

March 1.—Dr. Leonard Hill, F.R.S., "Caisson Sickness and Compressed Air."

March 8.—James Cantlie, M.A., M.B., C.M., D.P.H., "Plague and its Dissemination." Sir Shirley Forster Murphy, M.R.C.S., will preside.

Wednesday afternoon, at 4.30 o'clock:—

March 15.—Colonel Charles Edward Cassal, V.D., F.I.C., "The Adulteration of Food." The Right Hon. the Lord Mayor of London will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

February 9.—R. A. Leslie Moore, I.C.S. (retd.), "Indian Superstitions." Lord Lamington, G.C.M.G., G.C.I.E., will preside.

March 16.—Claude Hamilton Archer Hill, I.C.S., C.S.I., C.I.E., "Education in India."

April 27.—Sir Thomas Henry Holland, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord Avebury, D.C.L., LL.D., F.R.S., will preside.

May 25.—W. R. H. Merk, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

February 28.—The Hon. Sir Richard Solomon, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "The Resources and Problems of the Union of South Africa."

April 4.—Captain R. Muirhead Collins, C.M.G., "Australia and her Resources."

May 9.—F. Williams Taylor, "Canadian Banking."

CANTOR LECTURES.

Monday Evenings, at 8 o'clock :—

Professor ADRIAN J. BROWN, M.Sc., "Brewing and Modern Science." Four Lectures.

Syllabus.

LECTURE I. — FEBRUARY 6. — Introduction. Dr. Graham's Lectures Thirty-seven Years Ago—The Brewing Process a succession of Complex Biochemical Changes—Barley: Classification of types used by the Maltster—Barley from the Agriculturist's and Brewer's Points of View—Present Position of Knowledge regarding Characteristics of Malting Barley—Results of recent Experiments on Barley Cultivation in Ireland, etc.

LECTURE II.—FEBRUARY 13. — "Malting." Constitution of the Barleycorn — Character of Changes during Germination—Investigations of the Biochemistry of Germination—The Barleycorn a highly-specialised seed, etc.

LECTURE III.—FEBRUARY 20.—"The Mashing Process." The Chemistry of Starch and its Transformation Products—Protein Changes during the Mashing Process.

LECTURE IV.—FEBRUARY 27.—"The Fermentation Process." Previous Treatment of the subject by Dr. G. Salamon in 1888—The Pure Yeast Question in Brewing—Zymase and Modern Views of Alcoholic Fermentation—Nitrogen Assimilation—The so-called "secondary" products of Fermentation, etc.—Conclusion.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 6...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor Adrian J. Brown, "Brewing and Modern Science." (Lecture I.)

Sanitary Engineers, Caxton Hall, Westminster, S.W., 8 p.m. Presidential Address by Mr. A. J. Martin.

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Society of, at the Institution of Electrical Engineers, Victoria Embankment, W.C., 7.30 p.m. Presidential Address by Mr. F. G. Bloyd.

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. W. Woodward, "The Evolution of Fire-Resisting Construction."

Engineers, Cleveland Institute of, Stockton-on-Tees, 7.30 p.m.

Victoria Institute, 1, Adelphi-terrace, W.C., 4 p.m. 1. Annual Meeting. 2. Rev. J. Sharpe, "The Last Century's Witness to the Bible."

London Institution, Finsbury-circus, E.C., 5 p.m. Dr. A. C. Haddon, "The Art of Palæolithic Man."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Professor W. R. Lethaby, "Greek Buildings."

TUESDAY, FEBRUARY 7...Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Sir Francis Younghusband, "Lamaism in Tibet."

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. W. Mott, "Heredity." (Lecture IV.)

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m.

Photographic, 53, Russell-square, W.C., 8 p.m. Mr. A. E. Salt, "Primary Batteries and Small Electric Lamps for the Dark Room."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Dr. W. N. F. Woodland, "On the Structure and Function of the Gas-Glands and Retia Mirabilia associated with the Gas-Bladder of some Teleostean Fishes, with notes on the Teleost Pancreas." 2. Professor J. Cossar Ewart, "Skulls of Oxen from the Roman Military Station at Newstead, Melrose." 3. Mr. George P. Farran, "Plankton from Christmas Island, Indian Ocean.—I. On Copepoda of the Family Corycæidæ." 4. Mr. H. R. Hogg, "On some New Zealand Spiders."

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m. 1. Dr. W. E. Dixon, "The Codex and the Medical Profession." 2. Dr. W. J. Uglow Woolcock, "The Codex and Pharmacy."

WEDNESDAY, FEBRUARY 8...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Captain A. J. N. Tremearne, "Some Nigerian Head-Hunters."

Biblical Archæology, 37, Great Russell-street, W.C., 4.30 p.m.

Geological, Burlington House, W., 8 p.m.

Automobile Engineers, at the Institute of Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Report of the H.P. Formula Committee, with notes by Mr. Dugald Clerk and Mr. G. A. Burls.

THURSDAY, FEBRUARY 9...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. R. A. Leslie Moore, "Indian Superstitions."

Cyclists' Touring Club, Metropolitan District Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. R. D. Maddock, "Cycling in the Swiss Highlands."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Child Study, 90, Buckingham Palace-road, S.W., 7.30 p.m. Mr. Cecil J. Sharpe, "Recreational Activities: English Folk Dances."

Architects, Society of, 28, Bedford-square, W.C. 8 p.m. Colonel F. S. Leslie, "The Turned Lattice Work of Egypt."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. E. Stanley Roper, "Classical Song."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. P. Chalmers Mitchell, "Problems of Animals in Captivity." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Rev. T. T. Norgate, "On the Edge of the East—Dalmatia, Bosnia, and Herzegovina."

Optical, in the Chemical Society's Rooms, Burlington House, W., 8 p.m. 1. Annual Meeting. 2. Presidential Address on "Astigmatism in Lens Systems."

Electrical Engineers, Victoria Embankment, W.C., 8 p.m. 1. Mr. W. T. Taylor, "Long-Distance Transmission of Electrical Energy." 2. Discussion on Messrs. R. Borlase Matthews and C. T. Wilkinson's paper, "Extra High-Pressure Transmission Lines."

FRIDAY, FEBRUARY 10...Royal Institution, Albemarle-street, W., 9 p.m. Sir Sidney Colvin, "Robert Louis Stevenson."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) (Vernon-Harcourt Lecture.) Mr. W. H. Hunter, "Rivers and Estuaries." (Lecture II.)

Astronomical, Burlington House, 5 p.m. Anniversary.

SATURDAY, FEBRUARY 11...Educational Handwork Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 3 p.m. Presidential Address, by Mr. H. Holman, "Educational Handwork—Some Hopes and Fears."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. T. G. Jackson, "Architecture: the Byzantine and Romanesque Period." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,038. VOL. LIX.

FRIDAY, FEBRUARY 10, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 13th, 8 p.m. (Cantor Lecture.) Professor ADRIAN J. BROWN, M.Sc., "Brewing and Modern Science." (Lecture II.)

WEDNESDAY, FEBRUARY 15th, 8 p.m. (Ordinary Meeting.) GEORGE A. STEPHEN, "Modern Machine Bookbinding." JOHN MURRAY, J.P., D.L., F.S.A., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES ON "BREWING."

On Monday Evening, the 6th inst., Professor ADRIAN J. BROWN, M.Sc., delivered the first lecture of his course on "Brewing and Modern Science."

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, February 9th, the Right Hon. Lord LAMINGTON, G.C.M.G., G.C.I.E., in the chair. A paper on "Indian Superstitions" was read by Mr. R. A. LESLIE MOORE, I.C.S. (retired).

The paper and discussion will be published in a subsequent number of the *Journal.*

CANTOR LECTURES ON "PYROMETRY."

The Cantor Lectures on "Pyrometry," by Mr. Charles R. Darling, A.R.C.Sc.I., F.I.C., have been reprinted from the *Journal*, and the pamphlets (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John-street, Adelphi, London, W.C.

A full list of the Cantor Lectures which have been published separately, and are still on sale, can also be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

NINTH ORDINARY MEETING.

Wednesday, February 8th, 1911; CARMICHAEL THOMAS, Treasurer of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Crook, Thomas Mewburn, R.B.A., 10, Gainsborough-road, Bedford Park, W.

Genge, Henry Arthur Pope, Ootacamund, Madras, India.

Green, Richard Crafton, Newport, Essex.

Grundy, Cuthbert Cartwright, R.I., R.C.A., Homefield, Blackpool, Lancashire.

Gummá y Marti, Alfredo, Calle Universidad 30, Barcelona, Spain.

Heys, John, Heysham, Marine Approach, South Shields.

Lawrance, Dilipa John Skillern, 16, Infantry-road, Bangalore, India.

Lawrance, John C. Skillern, B.A., LL.B., Kirkton, 16, Infantry-road, Bangalore, India.

Lloyd, William, 29, Bridge-street, Staines.

Pott, Miss Constance M., 81, Cornwall-gardens, S.W.

Smith, Alexander Monro, 2, Denton-road, East Twickenham.

The following candidates were balloted for and duly elected members of the Society:—

Daneff, St., LL.D., Sofia, Bulgaria.

Forman, Robert Brodie, High Pastures, Elmswood-road, Aigburth, Liverpool.

Gunn, Donald, Hogtrow, Hook Heath, Woking.

Hudson, Philip Reginald, A.R.S.M., 807, Majestic-building, Denver, Colorado, U.S.A.

Lal, Pyarai, Zamindar of Burotha, Aligarh, India.

Schoenfeld, L. S., 807, Majestic-building, Denver, Colorado, U.S.A.

Shamasastry, R., B.A., Government Oriental Library, Mysore, India.

Simkins, Arthur C., M.E., 807, Majestic-building, Denver, Colorado, U.S.A.

Tattersall, Alfred Rishworth, 75, Mark-lane, E.C.

Vernon, Arthur Longley, 10, Abbey-road, St. John's Wood, N.W.

Whiteley, Richard H., National State Bank Block, Boulder, Colorado, U.S.A.

Worsham, Ernest Lee, State Board of Entomology, Atlanta, Georgia, U.S.A.

The paper read was—

SOME NIGERIAN HEAD-HUNTERS.

By Captain A. J. N. Tremearne, B.A., D.Anth., F.R.G.S., F.R.A.I.

I.—Introduction.

One of my first experiences of the Kagoro was somewhat startling. I had been amongst them the previous month, and, as tribute had not come in as quickly as it ought to have done (some being more than two years overdue), I had given them a slight hint that there were other and stronger arguments on my side than mere words. The road from Jemaa is steep and very bad, and as I emerged from a path in thick bush into a clearing, there, in line with their bows at full stretch and arrows fitted, were some thirty men advancing towards me. I had no time to call the escort, who were some distance behind, and to have retired would have been fatal; so, feeling very nervous myself, I rode up and told them not to be afraid, my orderly calling out in Hausa, "It is peace." I found that they were out after small game only (mice and rats), so we were soon friends. In the old days, had a solitary trader met a hunting party, his skull would soon have decorated a hut, for although mice may furnish good sport, men provide much better.

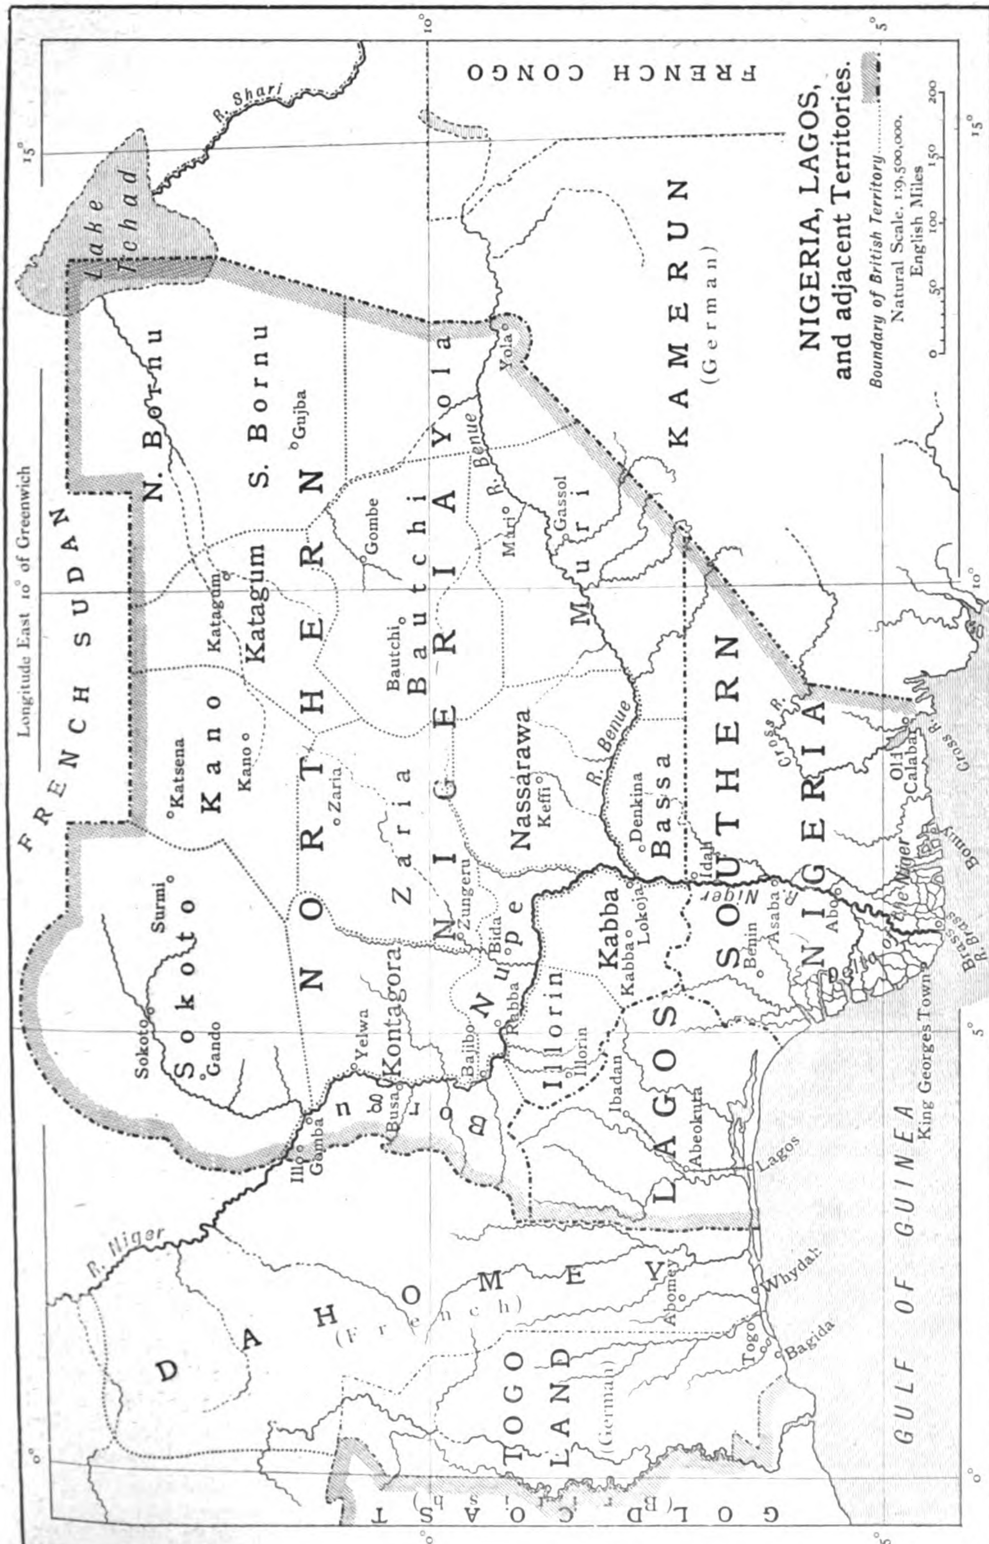
A political officer is usually one of the last persons to whom the natives in his district will confide their secrets, for (1) he has to see that they pay their tribute—and a tax-collector is not popular even in England; (2) he has to judge them by standards very often quite different from and even opposed to their own, so they tell him nothing lest he should see some wrong in their customs unsuspected by them; and (3) he has to put down many practices (head-hunting, for instance) which they look upon as necessary to their religion and well-being. Again, with many tribes (the Kagoro amongst them) any persons talking of religious beliefs may be stoned to death, so they are naturally very reticent, even though they regard a white man as a "big Juju" and as being connected with the supernatural. Savages, too, cannot keep their thoughts concentrated for any length of time, and after about half an hour one has to give up questioning them. Lastly, it is very seldom that a political officer can devote sufficient time to any single tribe in his district to know them properly. If he has the opportunity to find out their customs, he certainly will not have leisure enough to learn the language also, so he must depend upon more or less reliable interpreters. No man can be an encyclopædia.

These notes do not claim to be anything like a full description of the people with whom I was in touch for fourteen months, for in addition to the above reasons I should mention that a patrol had punished some of the tribes in June, 1908, just before I arrived at Jemaan Daroro; I accompanied one twelve months afterwards (August, 1909), and another went there early last year. It is therefore likely that a few statements may have to be modified when these tribes have been longer under observation, though in all sixteen authorities were examined with regard to the Kagoro, Moroa, Attakka, and Katab customs, and four with regard to those of the Kajji and Jaba, and no statement is made on the word of less than five of them, or else on the evidence of my own eyes. Luckily, nearly all spoke Hausa, so we could establish direct relations.

Measuring the heads was a delicate proceeding, as there was a chance that they might wish to keep a record of mine, and in a more substantial manner, so it was not until I was due for leave that I attempted it in their own towns. By that time the people had become accustomed to the idea, and, as each one received a present, and was told the book in which the entries were made was a magic one, I had not so much difficulty as was expected. I could, however, not get any women. I suggested it once at Tuku Tozo, and within half an hour the town was empty; this was after I had taken the photographs, though.

These notes refer to the Kagoro. The Moroa are so much like them that, except where pointed out, their customs, etc., may be taken to be similar. The Kajji also resemble their eastern neighbours. The other tribes are mentioned, here and there, only for the sake of contrast or comparison. I do not pretend to a knowledge of all of them.

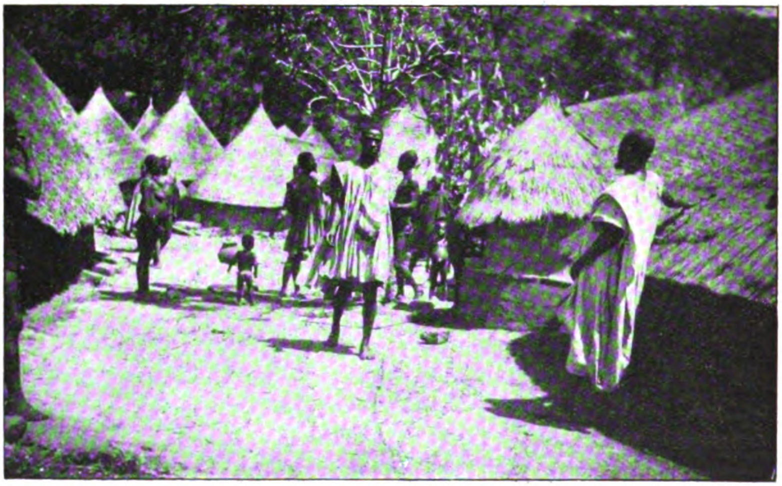
There is, however, one thing I think I may say of all, and that is, although they were



THE COUNTRY OF THE HEAD-HUNTERS LIES BETWEEN LAT. 8°-9° N. AND LONG. 8°-9° E.

sometimes shy, and always dirty, I soon became quite fond of them, and found them to be the same as most unspoilt peoples, viz., "but simple, overgrown children, playful . . . nearly always amusing, and often lovable." * Unfortunately for them, tin has been discovered near their country, and I fear that in a few years they will be as useless, from the anthropological point of view, as are the Sierra Leoneans of to-day.

The next slide will give you an idea of how some of the information was collected, though most of the religious part was learnt in private. This view is really one of a trial; not exactly as conducted at the Old Bailey, perhaps, but much better suited to the present wants of the country than an elaborate procedure would be.



A Kajji Village.

II.—Country—Origin—History of Kagoro, Moroa, and Jemaan Daroro.

Country.—The Kagoro, a naked, head-hunting West African tribe, occupy part of the north and west faces of a ridge of steep, high mountains running from the Bauchi into the Nassarawa province of Northern Nigeria. All but one † of the towns are built at the foot of the ridge, and nearly all on the north face are defended by labyrinths of euphorbia hedges, which sometimes reach a height of 12 to 15 feet. There are no stockades. In the slide can be seen the town of Kukkum, with the mountains behind. The total population is about 7,000, but this estimate is only approximate, for it has, up to now, been impossible to assess the people properly, as most of them run away on the appearance of a European.

Origin.—The Kagoro* say that they came long ago from Bauchi country westwards to Nimbia (Nassarawa), and from there they passed, after a short stay, to where Fada Kagoro now is. The leader of the party was Apak, after whom one of the towns is named. They there found the ruins of habitations of a former forgotten people—perhaps the makers of the stone axes discovered in the vicinity. The Kagoro themselves say that they have always regarded these as having been made by the splintering of rocks by lightning (this seems to be a general belief amongst the natives), and have never heard of their being used as tools, but the *Agwam* of Ogban recognised one shown him as an axe.

As the people have no records of any kind, the story of their origin is very hard to prove or disprove. One thing which supports their story—an important point too—is that in the towns on the northern face the sacred groves are all to the south, and the people first look in that direction when performing their mystic rites, the reason given being that they face

* "The Niger and the West Sudan."

† Lieutenant Matthews, R.A. (who relieved me as Political Officer), says he has heard that there are several villages on top of the hills, but that they have not yet been visited.

* Professor A. H. Keane mentions a tribe of Kagoro in "Man, Past and Present," but they are evidently not connected with these people.

their place of origin—while in those on the western face of the range the groves are to the north, and these towns, it is said, are colonies from Fada * Kagoro. As hardly anything is known of the languages of the Bauchi plateau no comparison can be made, but it is worth noting that the salutation is almost the same (*sham* or *sha*), though the tribes do not visit one another, and that all are head-hunters.

It is said that when the Kagoro first came to the country they now inhabit, they did not know the use of the bow and arrow, and this is possibly correct, for the Sa(r)rikin Jemaa told me that the Attakka learned their arrow poison from the Kibbo (Bauchi) only about twenty years ago, and that they taught the Kagoro; the Gannawarri use spears to-day. The place was so overrun with wild beasts, the legend goes, that they had to live underground and make tunnels to their farms. This makes one suspect that they were originally troglodytes, like the Nadu tribe to the south; they still have caves where they store their food, and which they use as hiding-places when attacked.

History.—It seems that for a long time they were ruled by councils of elders, and that it was not until the Kajurawa forced them to pay tribute that they chose a chief. There had been desultory fighting for many years without much result on either side, but about 120 years ago, so far as I can make out—possibly due in some degree to the wanderings of the Filani—the Kajurawa demanded a regular payment, and the Kagoro were not strong enough to resist. Two slaves had been asked for, so the Kagoro called a council to decide what should be done. A youth, Gundong, said he would supply the slaves if he were made chief (*agwam*), and this having been agreed to, he struck a silk-cotton tree (*ukum*) with his stick, and immediately two young slaves appeared, a male and a female, who were given as tribute. A simpler explanation occurs to one who knows their gentle habits, and that is that this was the beginning of the capture of passing strangers, which has been stopped only during the last three or four years. In fact the Kagoro say that before that time they were not head-hunters, nor had they any slaves.

Gundong was thus the first *agwam*. He is said to have reigned fifty years, and on the day of his death the cotton tree withered and died. His brother, Bishut, followed him, and lived for another forty years. There was an interregnum for some time when Jigya, or Jigga, played the part of a tyrant and at last had to run away and found a town of his own. The people then appealed to the Sa(r)rikin Jemaa to choose a chief, as they could not agree amongst themselves, and each town was fighting its neighbour. Bishut's son, Mungu, was appointed, but he died seven years afterwards, and was succeeded by Kaka, his brother, the present ruler (seen with his wives in the next slide), who was appointed District Headman by the Government in 1905. These chiefs were in no way subject to the Filani, although they asked the Sa(r)riki to choose them a chief. Jemaa, with Zaria's help, several times defeated the Kagoro, but also suffered some reverses, and never succeeded in subduing them, nor in making them pay tribute. The Kagoro people's first experience of a British expedition was in 1905, since when conflicts have taken place annually, and even yet three of the towns are not under control. I had to recommend two patrols during 1909. The first of these inflicted but little punishment, as there was hardly any resistance, and operations had to be suspended on account of the "rains." The second was opposed, and the medical hammocks were captured and held for some time as trophies of war. On this occasion three of the five Europeans, and many of the native soldiers and carriers, were badly stung by bees. After Gundong had given his slaves, the head of each family took it in turn to provide the annual contribution, and would seize even his own grandchildren. The towns have now been roughly assessed, and most of them have paid tribute to the Government direct.

There are councils consisting of all the heads of families; they form courts to try important cases, consult the oracles about war, etc., and practically control the chiefs.

The Attakka are now under control,* but it has so far been impossible to study them. They are head-hunters like the Kagoro, they dress in the same way, and their customs are said to be similar. They probably number about 7,000.

The Gannawarri have been patrolled, but they are not yet thoroughly subdued. They are nearly naked cannibals, the little attire they have being different from that of the Kagoro, as are also their customs. They were not in my district, and I was unable therefore to visit their towns, though I went a little way into their country to settle a quarrel.

* *Fada* = capital.

* A patrol visited the country in December 1909 and subdued them: they proved very poor warriors.

The Moroa say that their ancestors came from Zaria country to Kafanchan (north of Jemaan Daroro), and from there Enniluchwi and his wife went east and founded Ungual Tukunia.

The Katab are mostly in Zaria province, only one town being within the Nassarawa boundary, and I could not therefore study them. I was told that they originated in Kachicherri, north of Moroa. "There is a big rock, the Dutsin Kerrima," I was told, "where sorcery is practised; cattle were sacrificed there long ago. The demons* are very powerful, and earth is taken from the rock by the Filani, and mixed with potash for their cattle. Years ago Awudu, Sa(r)rikin Zaria, when subduing the Katab, gave the people a black bull to sacrifice, on the advice of his mallams.† Even now on Sunday and Friday nights the hill is luminous, and white cattle mount on top of the rock and walk about tended by a white Filani girl." I could not test the truth of this; the mountain may be a volcano.

The Kajji also resemble the Kagoro, but not so much as the Moroa. They are now thoroughly under control (as are the Moroa). They claim descent from the north-west, and this is borne out to some extent by Canon Robinson (in "Hausaland"). The late Lieutenant Boyd-Alexander visited the Kajji and Jaba country, but not, apparently, that of the Kagoro.

All these tribes are very good agriculturists, the Moroa being perhaps the best. They raise a great deal of guinea-corn and millet every year, but unfortunately make most of it into beer—or, as they call it, *akann*—so that from June to October they are usually in a state of semi-starvation, and have nothing but some bitter roots and what they can buy or steal. It is —as far as these peoples are concerned—a pity that the importation of liquor is prohibited, for they will drink, whatever we do, and if able to obtain gin (which would apparently be much less harmful than *akann*‡) they might keep their grain for food, and would then have less temptation to loot their neighbours' supplies, and so be more inclined for peace.

History of Jemaan Daroro.—Jemaan Daroro has conquered most of the surrounding country but could not subdue the Kagoro nor the Attakka. The following account was given me by the chief (Sa(r)riki), who is shown in the next slide, with the judge (Alcali), the chief's eldest son (Mada(i)ki), and others.

A mallam of Kebbi, named Usuman, having obtained leave from (Sheik) Othman to preach the Koran in Zaria, came about 100 years ago to Kachicherri and taught among the Filani there. Those people were at that time living in *rugas** with their herds, but they had villages where their slaves (*rundawa*) were allowed to live and farm on reaching maturity.

On the outbreak of the *Jehad* the Filani all ran away and came to a town near the mountain of Daroro† overlooking the present Jemaa. About a year afterwards Mallam Usuman and Abdurahmanu, their chief, camped on a hill N.N.E. of the present Sa(r)riki's house, and close to the river Jampallam, the people gradually spreading over the ground now occupied by the town.

It seems that the Sa(r)rikin‡ Kajurawa, in whose country they were, had called all his chiefs together on hearing that Zaria had been taken by Mallam Musa, and had decided to wipe out the whole Filani community, as they feared that if they left them, they themselves would be conquered later.

Now, the Sa(r)riki had a Filani girl, Indema, as a concubine, and, being very fond of her, he foolishly told her of the plot the evening before it was to have been carried into effect. Naturally Indema soon afterwards said she felt very ill, and that she would have to get some medicine from a man at Ungwal Tagamma—where the Filani were. The Sa(r)riki offered to send a slave, but she said she must go herself—love must have been very blind in this case—so he gave her a cone of salt § as a present for the "doctor," and sent her off with some slaves as an escort.

On reaching a stream near Ungwal Tagamma, she bade her attendants wait while she bought some butter, and, going on alone, she went to Abdurahmanu the Chief of the Filani there, and told him. Indema having left again, he at once called his people together, and they all got away in the night; so next morning when the Kajurawa came to kill them they found only the very old and very young cattle which were unable to travel, and had been abandoned.

* This account was given me in Hausa, the word used was Aljen, not Kurua—a spirit, shadow.

† Mohammedan priests or learned men, also magicians.

‡ Report of the Committee of Inquiry into the Liquor Trade in Southern Nigeria. Sir Harry H. Johnston ("Liberia," p. 988) also says:—"The use of this much-decried form of alcohol [trade gin] in the interior of Liberia, as in other parts of West Africa, seems to be much more medicinal than anything else."

* Filani temporary shelters.

† Daroro probably means "high," from the word "to look around."

‡ Sa(r)riki=chief; sa(r)rikin=chief of; *a* as in sat.

§ Salt is in this district a form of currency.

They followed the Filani as far as the river (between Mada(i)kia and Kafanchan), and killed a few, but they were driven off with the loss of thirty-three horses, and the main body of the Filani escaped. Indema did not flee but returned to the Sa(r)riki, who was so furious that he had her thrown alive into a hole and stoned to death.

The Filani on coming south drove out the Daroro people towards the town of Nindam, the only one now possessed by the tribe. The Kagoro at that time were quite friendly, for the Filani had not commenced slave-raiding. About four years afterwards Mallam Usuman was sent to Mallam Musa (then Sa(r)rikin Zaria) to obtain a flag and a name for the new settlement, that being the procedure for the official recognition of a town, and when Mallam Musa asked where had they come from, Usuman answered that the party (*jemaa*) had settled close to the mountain of Daroro. "Very well," said Mallam Musa, "the name of your town will be Jemaan Daroro," and he then gave Usuman a flag, a robe, a turban and a fez to be bestowed in his name upon the man whom the Filani should choose as their chief.

While at Kachicherri, levies of cattle had been made by the Kajurawa on special occasions, *e.g.*, if the chief's wife gave birth to a child 100 cattle were demanded, if the chief's son's wife had a child twelve head, and any of the sa(r)rakuna* on similar occasions took ten, but no regular tribute had been paid. On arrival at Jemaa these presents were discontinued.

For some years the Kajurawa were continually attacking Jemaa, and at first it was all the Filani could do to keep them in check; in fact, on one occasion, the pagans actually rode through the town, only to be driven out again. However, after a great fight lasting seven days, the Kajurawa were at length defeated and pursued, those who escaped returning to Zaria, only to be conquered later on by Mallam Musa.

It seems to have been about 1810 (probably two years after the Kajurawa were scattered) that Mallam Usuman paid his visit to Zaria. On his return the election lay between himself and Abdurahmanu, and he was chosen, the latter chief installing him. Mallam Usuman then returned to Zaria with the news, and was taken by Mallam Musa to Sokoto† to be officially recognised. He reigned until 1833, when, feeling too old to continue, he took his son Abdulahi to Zaria to have him appointed in his stead, and Usuman died the following year. During his reign Ayu had been conquered, and most of Numuna, Karshe, Moroa and Kajji.* Some Ayu people are shown in slide 7. Lander is said to have visited the town about 1827. He is supposed to have come from the north or north-west and to have wished to go to Bauchi, but as the road at that time was impassable he had to return.

* Petty chiefs, princes, etc.

† Sokkotu would represent the sound much better, and would apparently be quite as correct, but the above is the official spelling.

Abdulahi I. (1833–1837) was the eldest son of Mallam Usuman. He went with the Sa(r)rikin Zozo (Zaria) to Lafia Beriberi to help the chief of that town against some of the surrounding tribes. During his absence the Kagoro attacked some people at Mongwe—a suburb of Jemaa—and killed forty-two. Abdulahi then returned, and Jigya and Tafa were destroyed, the Kagoro losing thirty-one. He then went back to Lafia, and was soon afterwards shot in the neck with an arrow and killed when attacking Kwachigiddi.

Musa (1837–1842 and 1847–1850), Mallam Usuman's second son, then became chief, being appointed by Abd-el-Karimi of Zaria. He was a drunkard, and Hamada, the new suzerain, threatened to depose him, calling him and Abdurahmanu to Zaria, but dying before he could carry out his intention. The new Sa(r)rikin Zaria (Mahamma Sani) did so later, and appointed the old chief Abdurahmanu, banishing Musa from Jemaa territory.

Abdurahmanu (1843–1847) was now very old, and after three years was deposed through the machinations of Musa, who was again appointed, only to be again removed. Musa seems to have been a great warrior, for, in conjunction with Abd-el-Karimi, Ninzam, Kagoma, and the rest of Numuna were conquered, and the Kagoro were defeated and most of their crops destroyed in a war lasting some months. They would have been annihilated had it not been that a mallam had a dream and prophesied that whoever finally conquered them would die within a year. The war had then lasted some twelve months, and on that Sa(r)riki Abd-el-Karimi retired, as he could get no supplies—the Kagoro having buried all their remaining grain—and the war was abandoned. The Kagoro had been brought to such straits that they afterwards came to Jemaa to beg for food, and 100 of them were taken to Zaria as slaves. A similar thing happened when Sa(r)riki Awudu of Zaria

* Districts of surrounding tribes.

and Adamu of Jemaa fought them. The prophecy is supposed to be still in force. The Kagoro were thus never properly conquered by the Filani, and they never paid tribute to Jemaa, though the Kajurawa had taken slaves from them annually.*

Adamu (1850–1869 and 1881–1885), a full brother of Abdulahi, succeeded Musa. Except for Abdurahmanu, the two branches of Mallam Usuman's family seem to have furnished chiefs alternately, each taking it in turn, with Zaria's sanction, to eject the other. The usual charge seems to have been drunkenness, though there is no doubt that the claimant who brought the best presents to the suzerain was always the most successful, and, theoretically, the most temperate.

Mamma Adda (1869–1881 and 1885–1888), son of Mallam Usuman, also had two tastes of power, being finally replaced by the present chief.

Abdulahi II. (or Matchu) began to reign in 1888. He is the son of Abdurahmanu, son of Mallam Usuman, and was appointed by Sa(r)riki Yerro of Zaria, while fighting in the Kagoma district. Abdulahi has seen a good deal of service, having been wounded eight times altogether.

There had been wars with Keffi in the time of Adamu, but the fighting had been stopped by the Emir of Sokoto. However, about 1893 trouble arose with the late Magajin Keffi (Maloney's murderer) over land near Tsaunin Kolere, some of which was still in dispute in 1909. The Keffi people came in 1895 as far as Numbu while the Sa(r)rikin Jemaa was at Zambar, but the latter drove them out, and appealed to Sa(r)riki Yerro of Zaria, who decided in favour of Jemaa as regards the Numuna and Ninzam portion.

About four years later a plot was formed to replace Abdulahi by his brother Usuman, the ex-Sa(r)rikin Jagindi—a town founded on a deserted pagan site by the Filani in the reign of Adamu — the chief conspirators besides Usuman being Umoru Sa(r)rikin Delle, and Shemaa, a Filani. Another was Mallam Momo Tsula, since made (in-)famous by his work at Abuja last year where he tried to seduce soldiers and raise a revolt, but was captured and imprisoned. Usuman had been deposed by his brother and had gone to Keffi, but returned to plot, his supplanter bringing the news to Sa(r)riki Abdulahi at Jemaa, who persuaded a man, Dan Zabia, to go to Umoru's house at night and murder him. The death of the Sa(r)rikin Delle so enraged his followers that the whole of the Jagindi people at once rose, and were soon aided by the Kagoma and Kajji tribes, and by Dangoma. Fighting went on until 1903, when the Resident of Keffi intervened, and a year afterwards Usuman and Shemaa were deported.

No resistance was offered to the Europeans by Jemaa himself, but there has been trouble with every one of the native tribes surrounding. The Yeskwa, previously conquered, killed seventy-three out of a Jemaa force of 377 sent against them in 1900, and have since thrown off their allegiance, while the Ninzam have always been restless. I once had to hang a Ninzam chief for murder, and his brother sent a message to say that he would have my head to decorate his hut as compensation. We visited the town soon afterwards, but the people seemed to have "a previous engagement." The man sent in his submission, and on coming to me I made him chief instead of his brother. That, no doubt, seems a strange procedure to English ears, but one is only too glad to have a strong man in office if he has once acknowledged his defeat. Another Ninzam chief, when called upon for tribute, said he wanted to have a little fight first. He was, of course, obliged, and after about half an hour he sent a message to the effect that his people thought that they had the worst of the argument, and that tribute was forthcoming. Abdulahi is a strong man and requires firm handling; he naturally does not appreciate our control. He can hardly speak Filani, his children not at all, and they are turning into Hausas. All tribes which Jemaa conquered pay their tribute through him as suzerain; those still independent on our arrival, and since subdued by us, pay direct to the Government.

Owing to the fact that this country once belonged to the Kajurawa—the principal representatives of which tribe are now at Sanga—the courtesy title of the Chief of Jemaa is Sa(r)rikin Kajuru Filatihu.

Chiefs of Jemaan Daroro.

0. Abdurahmanu, principal chief at Ungwal Tagamma, came to Jemaan Daroro, but not recognised as Sa(r)riki until 1843.

1. Mallam Usuman, 1810–1833, first chief appointed by Zaria.

2. Abdulahi I., 1833–1837, killed in action.

3. Musa (first time), 1837–1843, deposed.

* The Kagoro are now thoroughly under control, and the prophecy has been disproved, for it is more than a year since their final defeat.

4. Abdurahmanu, 1843–1847, deposed.
5. Musa (second), 1847–1850, deposed.
6. Adamu (first), 1850–1869, deposed.
7. Mamma Adda (first), 1869–1881, deposed.
8. Adamu (second), 1881–1885, deposed.
9. Mamma Adda (second), 1885–1888, deposed.
10. Abdulahi II., 1888, still reigning.

III.—Scarification—Painting—Ornaments—Deformations—Clothing—Abnormalities—Invention.

Scarification.—All members of the Kagoro, Kajji, and Moroa tribes are scarified, and I am told the same holds good with the Attakka and Katab. Before the present pattern was adopted, each tribe had irregular cuts on the forehead only. There seems to be no religious significance, the lines being simply to denote race, and this must be correct if what they say about copying those of the Katab is true.

Males and females have the same marks on the head. These consist of numerous short perpendicular cuts right along the forehead from ear to ear, and long slanting lines (thirteen or more) on each cheek from ear to chin. In some cases (particularly amongst the younger men) a sort of zig-zag is added to the lowest line, but this is not compulsory; the other marks are, except in Tuku and Tuku Tozo, the people of which towns seem to be separating themselves from their northern relatives, and desirous of settling down peacefully under Jemaa. There are no euphorbia hedges there, and the "tails" of the women are of a special shape. Men may have in addition patterns on the chest, composed of rows of cuts about ½ in. to ⅓ in. in length and usually made slantwise, but they are voluntary and seem to be dying out. They are not confined to persons of rank.

These marks, I was told, are merely for the sake of ornament. They are not regarded as charms in any way. I could not find out what the patterns are intended to represent. The people said they did not know, and, if borrowed, this is probably quite true. Youths have the forehead scarified when able to hoe. The only raised scars I saw were on a Kajji man at Mersa, and this seems to have been an accident.

There is no doubt that Hausa patterns will spread, and be adopted even by the Kagoro, especially those which are supposed to have particular virtues—prevention of sickness, retention of wife's fidelity, etc.; many of the Kajji already have them.

Women's chests and backs are decorated with a regular pattern, so there is no need for them to undergo fresh pain for the sake of acquiring additional beauty. The first to be done are those lower down, and these seem to vary a little in design. When a girl reaches the marriageable age, the chest and back will be scarified, and when she goes to her husband the forehead. The rows of marks (made as in the men's chest patterns) may be increased in number, and the pattern on the abdomen may change. There is no danger of a Kagoro girl losing her "marriage lines!"

The scarifier is an important person, though he has not the exclusive right to operate on everyone, and the office is practically hereditary, for no man would teach a youth other than his own son or nephew.

Painting.—At feasts (marriages, etc.) both sexes paint a black stripe about one inch wide from forehead to stomach, and sometimes there may be a narrow line on each side, or each of these lines may be divided into three. No colours are used but black pigment and the red earth mentioned below, and no other designs are permitted. They are, of course, in addition to the scarification. The pigment is obtained from the unripe kernel of a certain thorn-tree (Kagoro, *illak;* Hausa, *gaude*), which is pounded up, mixed with water, and applied with the crushed end of a stalk of guinea-corn. For scarification (which is to be permanent) the incisions are painted with soot from the bottoms of the cooking pots, mixed with grease. The black and red are easily obtainable; so is white earth, but it is not used on the bodies, though it may be eaten in certain cases. There are no special artists for the painting, the people do it to each other, but for scarification a particular man is resorted to if one wants it well done.

The women usually smear their bodies with red earth (mixed with grease if they can get it), and the men, at certain times (*e.g.*, dances), may coat their legs up to the knees. This is said to be merely for the sake of ornament; it may also keep off insects. No distinctive dress is worn for prowess in war, though a male was not supposed to have attained to the dignity of full manhood until he had killed someone. There is a general idea amongst Jemaa people that he was not allowed to marry until this desirable feat had been performed, but the Kagoro deny this, and, judging by the early age at which youths obtain their brides, I feel inclined to believe them. On the return of

the hero to his house, his whole body was smeared with red earth, and he was carried in procession on the back of a friend, the women of the quarter meanwhile dancing and waving their hands before them, and singing his praises.*

It is rather surprising that they have not learned to put antimony (or sulphide of lead) on their eyelids, nor to stain their nails and hands with henna, as do the Filani and Hausas near them. They say they are afraid to ornament their hands lest it should interfere with their farming, and it is quite possible that this idea is fostered by the men so that the women will continue doing the hard work.

Ornaments.—No special badges of rank are worn—not even in war. The chiefs do not themselves fight, for a general is chosen by the people before the war commences. They, however, follow their men to drive them on if necessary. Youths may dress their hair; girls and women shave their heads. With Kagoro, some males up to about the age of twenty allow the hair to grow in a broad tuft from the forehead to the back of the neck, reminding one of children's wooden horses in England. Some Kajji say that a youth should not shave his head until he has two children, but this is doubtful. Some plait the hair instead and ornament it with beads, as do the Kajji, or arrange it in the shape of a mop. Young girls may do likewise, but shave the head when about six years of age, possibly because they have to carry weights (wood, water, grain, etc.), while the men very seldom do so. The older men usually allow the beard to grow, but the moustache may be shaved now and then. No shaving seems to be done while preparing for the harvest. I could not ascertain that there was any reason for this, except that the men were too busy on the farms, but I suppose there is one.

Deformations.—Both lips of the women are pierced for the reception of pieces of wood called *tichiaks*. These may be over 1 inch in diameter and about ¾ inch high. Sometimes the outer face is ornamented with beads, tin, or coloured earth. They are easily removable, but are supposed to prevent females eating fowls or dogs, the latter a very great privation. These people do not kiss each other, so there is no objection to the *tichiaks* on that score. The lips are usually pierced when the girl is about seven or eight, stalks of grass being worn at first, and then sticks of increasing thickness, until the *tichiak* itself can be inserted. These are of varying diameters, and when very large make the lips project so much that, seen sideways, the wearer has a pig-like appearance.

Both ears are pierced in the women, only the left in the men, and they are treated in the same way as the lips. In the southern towns the piercing of ears in males is not compulsory. Beads, usually in the shape of blue glass rings, are bought from Hausa and other traders, and worn; or if these be unobtainable, string or sticks will do, never metal. There seems to be no way of mending torn lobes, for I have seen several in spite of the fact that ear-rings are so light. The nose is not pierced, as with the cannibal Nadu to the south (*septum*), and the Beriberi of Bornu (right nostril), nor flattened. Teeth are not filed nor broken.

The heads of infants are massaged backwards to keep them from becoming too broad; both sexes are treated in the same way, the mothers (who do it) first warming their hands and using grease. The mode of carrying children does not influence the shape of their heads much. The women may bind themselves tightly after childbirth to avoid becoming permanently fat, but there seems to be no permanent constriction, and there is no artificial elongation of the mamma. There is no deformation of the feet or fingers.

Clothing.—The chiefs who have been recognised by the Government wear Hausa robes, and are called *agwams*. No other Kagoro wears any cotton of any kind, but Kajji and, to a less extent, Moroa men buy clothes from the Hausas if they can afford them. The males wear a leather triangular loin covering after they have reached the age of six or eight, possibly earlier if the father happens to have skins to spare; Moroa and Kajji men may wear cotton loin-cloths. Some wear another skin over the shoulder as a cape, the two front legs being tied together to serve as a cord, and enabling it to be shifted to the side exposed to the wind or rain. Both garments are made of goat or sheep skin, the hair being left on the

* Compare Dr. Haddon's remarks in "Head-hunters, Black, White, and Brown," page 394:—"There can be no doubt that one of the chief incentives to procure heads was to please the women. Among some tribes it was said to be an indispensable necessity for a young man to procure a skull before he could marry, and the possession of a head decapitated by himself seemed to be a fairly general method employed by a young man to ingratiate himself with the maiden of his choice. The fact of a young man being sufficiently brave and energetic to go head-hunting would promise well for his ability to protect a wife . . . The pride women feel in their men-folk who have taken heads is not confined to these people of Borneo; formerly amongst the western tribes of Torres States a young man who had taken a skull would very on receive a proposal of marriage from some eligible young woman."

latter, but not on that for the loins, which is tanned. There is no special "tailor," the skins are prepared by the wearers themselves.

Girls from three to four until married wear the *ivyan*, a girdle of loose native string—not plaited nor twisted—which is tied around, but lower than, the waist, a long end meeting the girdle again near the small of the back. This is an absolute sign of virginity. Married women wear a tail (*kunnok*) instead of the girdle, which is in shape something like a mushroom; some are long and thin, others are short and stumpy. The tail is made of a palm fibre very tightly drawn together and bound with string, the wide wheel-shaped part being plaited like basket work, and they may be left thus, or may be coloured red with earth to match the wearer's body; two strings of the same material attaching the tail to the waist. The next step in ornamentation is a row or two of beads around the edge, and then brass wire may be bound around the body of the *kunnok*, or it may be covered with sheet brass; finally, the under part may be decorated with beads in a regular pattern. The brass, is of course obtained from the Hausas. The beads (from them or other traders) are strung on thread, and then stuck on with liquid rubber, of which there is plenty in the country: they are not sewn in any way. The fancy patterns were, I think, invented by the Jaba, a tribe to the west of the Kajji; they are extremely rare amongst Kagoro women.

I was told that sometimes a bell is worn above the tail, but I do not know under what circumstances. The Tuku Tozo tails resemble a bell.

When a girl has been married her mother takes off the girdle, and a small branch or bunch of leaves is hung to a string in front. Many women—especially when old apparently—wear leaves both before and behind, though this is not compulsory, but those in front are a sign of marriage. At certain times (dances) leaves may be worn by young girls; this, perhaps, corresponding in some degree to our young people taking grown-up characters at fancy-dress balls. Tails and loin-coverings are not sacred to the owner, and if in good condition at the time of the wearer's death may be passed on to other members of the family. These peculiar articles are probably responsible for the old belief in tailed people in Nigeria.

No Kagoro, Kajji, Attakka, or Moroa woman would dare to attire herself in any other than the prescribed fashion, though the only punishment which would be inflicted is, apparently, the disapproval of her own people. The differences in the adornment and shape of the tail seem to be the only variations sanctioned. I have known girls, taken away when young, and dressed in Hausa cloths, at once to discard these for the *tichiak* and *kunnok* on their return. On the other hand, the mutilation of the lips is not at all popular amongst women of other tribes. Having to judge once between a husband who wanted his wife (a runaway slave from Sokoto) *Kajji-ised*, and the wife herself who thought her natural charms sufficient, I decided that she must adopt the leaves and tail as she was married, but that her lips were not to be touched, for the perforations should be made when the girls are young. They seemed to be satisfied; I am sure I was.

No head-covering is worn by either sex, but a cape—something like the sack with one side cut open worn by coal-heavers—is made of palm-leaves for protection against the rain. This may have been copied from those made by Hausas, their name for it (*kabiddo*) is often used. A sort of immense three-cornered grass hat is worn by Ninzams. There are no coverings for the hands or feet.

The Gannawarri women wear a number of iron rings in front and a kind of leather brush behind, but no leaves nor tail.

I have some figures concerning the height and other measurements, but I think we need not trouble about them to-night, and simply pass on to—

Abnormalities, etc.—There are no albinos nor persons with red hair, nor, apparently, any with an excessive amount of hair, or with none at all. Old people are looked after by their children—especially the fathers—but their death is nothing to be sad about, in fact quite the opposite, for the older and more important the deceased the greater the wake. They are, however, never killed.

If a child be an idiot or unable to move about it may be thrown into the water, "but not killed," so they say, though it comes to the same thing apparently. This usually happens when the child is between the ages of one and four, but in some cases he may be given a much longer time in the hope that he will recover. "It is evidently a snake and not a human being" (so I was told). "If, after you have thrown him into the water you go away, and then come back silently and hide yourself, you will see the child lengthen out into a snake." This was done at Jemaa, and in the surrounding districts

also. Matchu (blacksmith) says that his grandfather (Shobin) took a boy to the riverside and made him sit with his face to the stream. He and the boy's father gave the boy some *kunu*,* and while he was eating it they stole away and climbed a tree overlooking the river. Soon the boy glanced around, and, seeing no one, began to grow until he was as tall as a tree, turning at the same time into a snake. Shobin and the father were terrified and ran away, the former tearing his leg during the flight, the mark, which he had to his death, being, of course, an indisputable proof of the truth of the story. It is probable that once, on some former occasion when a child was thrown in, a crocodile or some other monster leapt up and caught him, thus terrifying the onlookers, and giving rise to this myth.

If a Moroa gives birth to an idiotic or deformed baby medicines are tried, even up to the age of ten years if necessary. The mother will nurse it for some time, and if it does not become normal may leave it with the father and marry someone else. When the father is convinced that it is useless to expect any improvement he calls in a Kagoro or Attakka priest, who will throw it into the river Kaduna. He himself has to hide, for the child turns into a pillar of fire and smoke,† and would consume him if present. The mother will never return to the house while the child is alive lest it prevent her having normal issue, but she may come back after its death. The Kagoro and Attakka have much stronger "medicine" than the Moroa, so they do the drowning themselves. It is just possible, judging from this and from the fact that the Moroa's time of probation is so long, that the Kagoro taught them the custom.

Invention.—The people are not very inquisitive nor anxious to learn new ideas, tools, etc., from their neighbours; they seem to be quite content to remain as they are, and simply say, "We Kagoros do not do so," or "Our fathers did not teach us." Thus even now, none of them (nor of the Moroa and others) can forge iron or make their agricultural implements, although foreign — generally Hausa — blacksmiths have been with them for many years. And they will not wear clothes, in spite of the fact that during the harmattan season their climate is very cold. They are, however, learning the Hausa language, but not that of the Filani, for the latter—having been slave-raiders—are their natural enemies.

They are courageous, and have made tribes much bigger than their own respect them. None have as yet been educated, so it is impossible to say whether they would readily return to their native state if once removed from their surroundings; but I should say that they would, judging from the way in which they cling to their attire. They have such a strong love of freedom and conservatism, that I do not think they would relinquish their liberty, nor take to any European customs without compulsion, and as that would be contrary to our principles we let them alone so long as they keep their roads open, and remain peaceful. The tax imposed is merely to remind them that they are no longer able to indulge their little hobby of collecting the skulls of their neighbours without bringing upon themselves the serious attention of a stronger power. The incidence is about one penny per head per annum; such a tax would be welcome here!

IV.—Habitations—Building—Decoration, etc.—Reoccupation.

Habitations.—Houses are built of red or black mud, and have grass roofs. The walls are 3 ft. to 4 ft. in height, and the roof is higher at the back of the house than at the front. Each house has one central door, or in a few cases two, opening into the compound, and each wife has a separate house for herself and her family. There is a porch or hall, extending along the whole width of the house, where wood is kept, and a verandah outside that, where the people sit in wet weather during the day, or outside in dry weather on palm-tree logs let into the ground. The porch has a doorway about 2½ ft. to 3 ft. high in the shape of a half-hoop. Between this and the sleeping apartment there is another doorway, closed by a sliding mat let into the wall. The outside doorway may also have a sliding door, or perhaps a curtain of string.

The arrangement reminds one somewhat of a Canadian railway sleeping-car, the verandah resembling the open-air space for observation, the porch, the smoking-room (where the fire is). Inside that are two compartments opposite one another, which can be compared to two sleeping-berths; in fact they are used as such, that on one side (I believe always the right) has a bed of palm-fronds or bamboos raised about one foot from the floor, and is for the husband

* Native broth.

† An English legend of a person changing into a ball of fire on plunging into water is mentioned in "The Science of Fairy Tales."

and wife, that opposite being for the rest of the family. Then, further on, is a circular room, in the centre of which is a large earthenware vessel for holding grain, built on stones, and there may be other smaller ones also.

The dome of the roof is over the granary, which is in the shape of an enormous vase (opening at the top), thus giving room for persons to climb into the attic and take the grain, or to hide if necessary, and also—so they say—to keep the smoke away from the rest of the house. There is no chimney of any kind, but it naturally goes to the highest part and escapes through the thatch. The smoke is probably also useful in keeping the grain free of insects to a slight extent. A man may have a compound to himself, or he may allow all his sons and their families to live there also, thus forming a miniature village. The houses are built on the ground level, none are on piles, but boys watching the crops have a scaffolding so that they can see over the grain.

Building.—I am told that anyone is free to build or farm where he likes on unoccupied land, provided that the spirits agree. The father chooses the site of the son's house, and places stones in circles, or threes, for the granaries to rest upon. The blood of a fowl is spilt as an offering to the people already buried there, or near, so that they may leave the house in peace, then a few leaves of the *Nok* tree are put in a hole in the spot chosen and covered over. This is supposed to bring good luck to the house. After that, the prospective owner invites all the "big men" to inspect it, and of course provides beer (*akann*), without which nothing is done. A little beer is poured three times on the place after three incantations, and an ancestor's aid is invoked, the rest being served out to the company. When they have drunk all they can get, they tell the man to remain in peace, and he starts building. When the house is completed, *tuk* (evening meal) is prepared (on this occasion I am told no beer is drunk—but I can hardly believe it), the people of the quarter are invited to share in the feast, and when all have eaten and departed the family enters.

No sacrifices are made when building (except for the fowl killed as above) or when felling trees, nor are any charms, tokens or coins put in the foundations, as with us. While on the subject I may mention that in Angwom (Ninzam) I saw a rooster which had been put into a pot let into a hole in the step of the outer porch, and as the neck of the pot was narrow, only his head could protrude. Fowls are often kept in pots for fattening purposes, but in this position the rooster acted as a watchdog as well, for no one could pass into the house without disturbing him. A man is free to farm on unoccupied ground, but he must obtain the consent of the spirits (which really means that of the elders) as above; the *meakwap* will sometimes cut the first sod, and beer is offered.

A fowl is killed when the corn is ripening, a hole is dug in the centre of the farm, and the blood of a fowl and leaves of the *narrankwoi* and *tongwai* are put in it. When the corn is ready for harvesting, fires are lighted of *kungut*, and the smoke enters everywhere and kills the insects. After the corn has been stored in the granary another fowl is killed, and the blood is smeared on the outside, the flesh being eaten by the men. Young women must not eat fowl "as their lips are pierced"—the old ones may, apparently. The blood has the same effect as the beer; it appeases the appetites of the ghosts, who will then allow the people to live in peace—until, of course, they are thirsty again.

The roofs are made of bamboos or palm-fronds in the shape of a dome. They are not regular though, for the poles from the top to the front of the house are much longer than those to the back, the apex being over the granary. The poles are lashed together with tie-tie, and look like a spider's web, as the lashings are in concentric circles. The grass stalks—about 5 ft. to 6 ft. long—are then joined together into a flat layer with tie-tie and rolled on to the poles, beginning at the bottom of the front and going first from side to side, and then round and round the house until the top is reached, where the knob is tied and may have two sticks thrust through horizontally, and a large egg or bottle on the top as a charm. Each roll of grass is tied to the cross-lashings and joined to the next roll.

When building the house the granary is first made—so that it may get the sun, and because it will take longer than the walls, being higher—and then the rest of the house.

The floors are trampled until hard, and sometimes charcoal is mixed with the earth (as also with the walls) to blacken it. Cowries are often inserted as ornaments, and arranged in circles or "dice-cup" patterns. Sometimes even the whole compound has a beaten floor.

Decoration.—The outer front wall of the house is usually decorated, even if the ornamen-

tation goes no further than a coat of red earth, and in some towns designs are worked out, as has been seen, the Kajji houses usually being far ahead of those of the Kagoro and Moroa people.

Sometimes the doorway itself is also ornamented by lines running around the space. All the lines are made by pressing sticks (straight or bent as required) into the soft mud when the house is being built. The dice-cup pattern is used on the body also.

The porch generally has a long trough-like shelf of mud running over the inner door (= the hat-rack), and the inner rooms also may be furnished thus; this is to place the calabashes in. Sticks or horns may be stuck in the wall to hang bow and arrows, etc., on, and I have also seen a hanging hook of wood something like a swizzle-stick, or an umbrella-frame upside down, it having been simply cut from the fork of a small tree, and not improved in any way.

Low wooden stools are used in the houses. Skulls of men, also those of the hartebeeste, antelope and monkey, are strung on a piece of native rope and hung up on the outside walls under the thatch to advertise the family's prowess,* and these are passed on as family trophies. There are some medicine-houses (although this is denied), but I can get no information about them from the Kagoro, and no alien is allowed to go near. A cave containing a large number of skulls was found by the first expedition. The Moroa have a house at Béniki, I believe, and it is said that there are others.

There is very little refuse. The ashes are put in the goat-house and are used as manure. the remains of the night's food are usually eaten next morning or given to the dogs or vultures, while any loose grain is soon picked up by the fowls and goats. Pits are, however, necessarily made when the house walls are being built, and whatever refuse there may be undisposed of is thrown in. The Kajji compounds are kept very clean, but the Moroa and Kagoro housewives are not so praiseworthy, and, as the people are not very careful, the air is not always so pure as it might be.

Reoccupation.—A house is reoccupied on the death of the owner, although he may be buried in the porch itself. If the owner has children—and this seems to include the occupier of the house (a wife) as well as the possessor of the whole compound (the husband)—he or she is always buried close to the porch; if he has none, he is buried outside close to the walls so that the roof will protect the grave. A compound has a house for each wife, outside granaries, goat houses, others for the preparation of food, and stables, etc. As stated before, the Kagoro towns with the exception of the five in the south, are all built at the base of the mountain spur, so as to give a retreat in the event of an attack. Caves up above are filled with grain, and in case of alarm are inhabited. The compounds are surrounded by euphorbia, the juice of which, it is stated, will blind anyone if it gets into his eyes—goat's milk is said to be the only remedy, and it must be applied at once—and if the people retire they let loose swarms of bees (*shoi*) which are even more effective than their arrows for repelling assaults.*

V. — Basket-Work — Pottery — Metallurgy — Machinery — Fire — Natural Forms — Writing — Weaving — Agriculture — Trade.

Basket-work.—The commonest form of basket in the northern towns is the *Uncharra*, for carrying millet, etc. This is in the shape of a calabash and the weaving is of the simplest form. The Tuku people make a basket with a handle, and there is another kind used for carrying water or honey, which is, I understand, made waterproof by being daubed with mud, but I was unable to procure specimens. It is not used as armour. Goat skins form bags for grain, but most are made of straw.

Pottery.—Baskets are not employed as moulds for pottery, for none is made, except in Kaderko and Duchui perhaps; all pots are procured from the Attakkas. There is no wheel. One method is to mould the fresh clay on to an old pot, as with Hausas and others. It is possible that the want of suitable earth was the original reason—though to all appearances the Attakka country is exactly the same as that of their neighbours—but there is certainly a prohibition against it now, for Attakka women who have married Kagoro men are not allowed to make pots at home, but must go to their own country.

* This custom is apparently common, for Dr. Haddon states ("Head-hunters, Black, White and Brown," page 107), writing of the Kiwai:—"The head was hung over a fire and all the hair singed off. During this process all the young girls of the village assembled and danced in a ring near—but not round—the fire, singing all the while. The head was then taken away, and all the flesh removed; after the skull was washed a carved peg was stuck in the skull, by means of which it was hung up on the main post of the house." And again (on page 115, of the Mawatta):—"Below one of the large houses there were clusters of human skulls hanging like bunches of grapes or strings of onions; these were the skulls of enemies killed in battle, and they were hung up as trophies."

* See *Journal*, No. 3,011.

They are, however, at liberty to return after having done so. It is said that ill-luck will overtake the Kagoro if they ever permit the making of pottery in their country. The Moroa also buy their pottery. The pots are black and quite plain, there being no decoration or varnish. Gourds or calabashes are of course very much used.

Metallurgy.—The Kagoro do not know that the stone implements found in the vicinity were once tools. As far as they know iron has always been utilised. When I pointed out the fact that only foreign blacksmiths had worked that metal for them (and are still doing so) they said that they did not know what had been used before. These blacksmiths in Kajji towns have special houses built very often in the form of a high cone. Brass is also obtained from traders. The only use I saw it put to was for ornamentation. The only silver in their country is our coinage, and this is too rare to be melted down to make ornaments as with the Hausas, but *tichiaks* are decorated with tin.

Machinery.—The millet or other stalks are first pounded by women in a wooden mortar to separate the grain. This is then winnowed in a flat shallow basket. The grinding is done with two flat stones, the lower one being placed at an angle inclining from the grinder to a calabash on the ground. The grain is poured on the higher end (near the woman) and by the time it reaches the calabash has become flour.

There are, I am told, no wells. They would not be necessary, as the towns are built very close to rivers.

Fire.—Fire, "which originated in the world from lightning," was formerly obtained from wood by the upright method. Several kinds of wood will do. The Moroa people say that they use this method even now in dry weather if not near a house.

The next method was by striking steel on pyrites or flint, and this is still very common.

It is now usually procured from the blacksmiths. When once fire has been brought to a house it is practically never allowed to go out except when fresh is sent from heaven,* and it is wonderful to see how long a stick will keep burning. Sometimes the embers are placed in chaff. Fires for warming (and also for cooking) are formed by putting three logs together so that their ends form a triangle, and a fire is lighted where they join. As a bit is burnt away the log is pushed towards the centre, and although there may be no flame this sort of fire seems to be inextinguishable—except of course in rain.

There is no religious reason for keeping the fire alight, I believe; it is simply for the sake of convenience, and—as with the Hausas—it will be gradually abandoned as matches are introduced, for the labour of collecting wood would then be lessened. The first fire for a new house is obtained from the nearest neighbour—if friendly; there is no need to wait in order to get it fresh from lightning.

Natural Forms.—No stone implements or arms are in use now, it is said. Gourds are employed as basins and drinking vessels, but not skulls (as, it is supposed, was done by the Ashantis). The pots made by the Attakkas resemble gourds. Some reeds are used for musical instruments.

No parts of animals are utilised for human defence. The Nadu have wooden helmets and skins to deceive animals, not the Kagoro now. Bamboo sticks with iron rings are used as clubs. Leaves of the fan-palm are sometimes laid on porches or outside shelters, but usually there is thatch underneath.

Writing.—There seem to be no writings nor even notches on sticks. As all villages are close together it would hardly be necessary.

I have not seen any representations of animals, etc., and none are scarified on people's bodies, but the natives understand English pictures.

They comprehended a rough plan of country drawn on the ground, but I have not succeeded in getting anyone to draw one for me.

To the bearer of an important message the sender may give a stick known by the receiver to be his as proof; the stick of the *agwam* is different from ordinary ones, and from that of another *agwam*, and most of the people have seen them at beer feasts, so they know them.

Weaving.—As there are no clothes there is no weaving done. I am told indigo is sold to the Hausas.

Agriculture.—Regular farms are laid out by everyone. The men dig and the women sow, the implements used being a hoe and a hoe-shovel used as a hoe.

These are made by the (foreign) blacksmiths, and are used after harvest as money in payment of tribute, giving of presents at death, cutting

* Sir Harry H. Johnston ("Liberia," p. 894) says:—"I have so frequently witnessed the ignition of the African bush by flashes of lightning, that I can well realise how the negro may have even been led into the use of fire by keeping alive and feeding the remains of a conflagration caused by the electric fluid."

off heads, marriage (to parents of bride), etc. No domestic animals are employed in the work of the farm.

Goat's droppings and ashes are used as manure. Land is allowed to lie fallow and there is a certain amount of rotation of crops, though this is better understood by the Moroa, who have but little spare land.

When the grain is ripening strings may be tied from one end of the field to another, and these are vibrated by a watchman (on a raised platform, probably, or in a tree), to keep off the birds and monkeys. If no string be available he will shout at short intervals.

Charms—bunches of leaves tied on sticks—are placed at the edges of the fields to prevent theft.

A man establishes his right to an unoccupied piece of ground by tilling it, and it is his until he allows it to go out of cultivation.

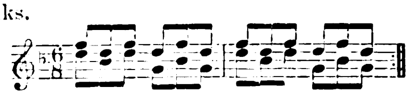
Trade, etc.—The fingers are always used for counting. For 1 the first finger is extended; for 2 the first two; for 3 the second, third and fourth; for 4 all the four fingers; and for 5 they are placed on the thumb. Both hands are used for the teens. For 20, etc., the hands may be opened and shut several times, or else the feet may be employed also.

There is no special class of traders, the bartering and marketing being usually done by the women. The custom of "the silent trade" does not exist.

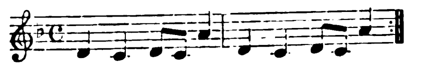
VI.—Music—Instruments—Dances.

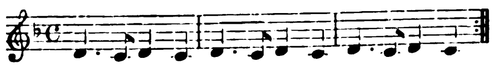
I was unable to hear more than one Kagoro song—and that, I believe, came from the Attakka. I could not get the words (which referred to marriage), but the refrain was—

A Kagoro youth accompanied his song on a native autoharp made of reeds. This instrument is common to many tribes, I have come across it even south of the Benue. I heard another tune at Fada Kagoro, but whether it was played by one or two boys I am unable to say, as I saw no trace of the player. The flutes on which it was played were made from guinea-corn stalks.



At Mersa (Kajji) I saw (and heard) a dance on three occasions. The instruments were horns and drums, one of the latter being large, and played like our big drum, the other was more of a tomtom. The horns were those of the antelope, two to three feet long, with a hole in the side near the point, and with about eight to twelve inches of a gourd fastened to the other end to give a wider mouth. A few of the players performed solos, and seemed to get sounds like those of a violin out of them, the intervals were so small they seemed impossible to write. The choruses were—





There are no words to the Kajji music, the people march round and round the band, taking three steps forward and then one back. Older women dance singly, but they may carry babies while doing so. Young women may catch hold of each other (as do the men), one behind the other, to the number of perhaps four; small unmarried girls may wear leaves for this. The women wag their tongues quickly from side to side and squeal. This sound is generally known by the Hausa name *kururua*. The dance is, I believe, intended to honour an important person; it was twice performed for my benefit, and once for that of a chief whom I had just appointed, but it—or something like it—is also performed at funerals. The band stands in a circle. After a time the big-drummer (the leader of this band) advances towards the centre, and is followed by the side-drummer and the horn players in turn. They go around a few times and then kneel in front of the person honoured for his reward. They never forget *that* part. An old woman may dance a *pas seul* at the same time, the other dancers standing still.

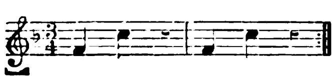
Another dance I saw was by Ninzams (also head-hunters) at Randa. Two men had drums, but none had wind instruments, the non-players holding short sticks in their hands. They sang the refrain several times (in Hausa) and then shivered violently. The translations are: "Our town is with (full of) young girls, the youths will have pleasure," and "Search for the whiskered one, ignore the salutation." What this last means exactly I do not know, and they could not explain, as they said the words had

been taught them by Mada (also head-hunters), who had evidently got them from the Hausa.

A few Hausa (or Filani) airs heard in Jemaan Daroro may be given, as they will probably be learned later by the surrounding tribes. The first is a woman's song; the singers move their bodies (particularly the buttocks) in time.

This is a serenade to the chief played several evenings a week on the algaita, a wind instrument which sounds like a clarionet. Sometimes the *e* in the last bar but one would change to *d* flat, an interval strange to our ears.

The last are salutations to a chief. The translations are: "See him, see him, see the King," and "May you alight (arrive) safely." They are played on long brass trumpets like



coach-horns, often in different keys. The time, three-four, is the nearest I can get, but sometimes it is very irregular.

Other Kagoro instruments are a flute and a kind of clarionet, both made of wood. A syrinx was found in Jigya, but whether this was native to the town or was imported I am unable to say.

These airs were not all in the key of *F*. I have written them thus for convenience.

VII.—War—Hunting—Relations of Animals to Man.

War.—There is a very close connection between the hunting and the war parties of these head-hunting tribes. A chase may easily be turned into a battle, even amongst the hunters themselves, when the arms for both are the same; and the search for beasts may become a hunt for men.

From the account given me by the Kagoro, it would appear that when they first came to the land they now occupy, they were dependent on the chase for their food, and that they lived in caves. Somehow or other they discovered the bow and arrow (even now the Gannawarri use spears on horseback), and began to drive off the dangerous, and kill the edible beasts.

It does not seem that all male adults must fight in case of war, but, judging by their general behaviour, I should not think any would refuse. The country is so small that the Kagoro are always within easy distance of their towns, so they go out in the early morning, fight by day, and return to sleep at night. They tried to surprise the patrol sent to punish them in 1908 about 9 p.m., but were unsuccessful. And this was the first night-attack Europeans had ever experienced in the district.* The warriors take food enough to last them for the day, but if fighting near their own houses their womenfolk will probably bring them something extra. There seems to be no need for any permanent organisation for war during peace, for all are in training, and none ever leave their houses without their weapons. Boys learn how to scout and take cover by practising with stones.

There does not seem to be any formal declaration of war, fights usually arising from sudden quarrels, but if there be any delay between the disagreement and the actual fighting, the women or people of a town friendly to both sides usually hear of it, and pass the word along.

Before a war is decided upon, the elders and priests repair to the sacred grove and ask the opinion of the ghosts. This is usually favourable, and then a leader is appointed, the *agwam wuta*. He is usually chosen for his skill in arms, and will not be either the chief or the head-priest, for these follow behind their troops, and cheer or drive them on as the case may be. Boys who have shown the right qualities in the sham fights with stones will be noted for posts as subordinate leaders when they grow up. Religion is conducive to warlike prowess, for (1) the strongest on earth will be the strongest in the next world, and (2) the ghost of a slaughtered enemy will attend the slayer. There is also, of course, the admiration of the belles of the village, and the effect of the stories and songs of the prowess of bygone heroes.

When the forces have assembled, the chief priest and the chief address them, and having

* Lieutenant Evatt, Middlesex Regiment, tells me that Mada and Nadu people attacked a patrol at night last year.

been handed over to the leader chosen, off they start. If in alliance with another tribe, the general of the tribe making the war will command the whole. Scouts are sent out in front to avoid surprise (up trees if necessary *), and to get news of the enemy, and the forces are disposed in accordance with the plan of campaign decided upon. When close to the expected battle-field the men extend. They keep a fairly good line but do not trouble about the step. All are on foot, there being but very few horses amongst the Kagoro; dogs are not used. They shout their war cry—*Wifu wifu*—and insult their enemies and boast of their own deeds.

When an enemy has been slain, the victor, on removing the head with his knife, will sing a special song about it, but there seem to be no other special songs. The Ninzam people have some, though, and sometimes the women accompany the fighting line, and sing to cheer them on. It is said that the Kagoro warriors do not sing any songs during the actual fighting.

Most of the towns are defended with labyrinths of euphorbia hedges, as mentioned before. There are caves in the hills, and here, if the town be attacked, the women will repair with their food and property. The men if driven out of the town may smash the beehives as they leave, so that the insects will attack the invaders. They seem never to have dug pits for their enemies, and this is surprising, for many of the surrounding tribes (Gannawarri, Ninzam, Yeskwa, etc.) do so. The Kagoro would be, I think, too much afraid of water to try inundating their enemy's country, but owing to the configuration such a course would in any case be impossible. Houses are never built on piles for purposes of defence, nor have the people any knowledge of earthworks, escalading or breaching, as there are no walls in the vicinity, but they cut paths through the cactus of other towns.

The weapons are (1) a wooden club, (2) a knife—bought from a Hausa or else made by a Hausa blacksmith, (3) the bow and arrow, (4) the sling, (5) the spear for throwing or thrusting, and (6) the shield. The arrows have iron heads with flanges, and are poisoned, the shafts being notched but not feathered; they are usually about 3 ft. in length, but Jigya used some 4 ft. 8 ins. long against the Patrol last year.

* Lieutenant Matthews writes:—"One of the Mada methods of fighting I have not heard of elsewhere. They tied goats to the bottoms of trees, the tops of which were covered with creepers, and, when people came to unloose them, they sniped them."

Fire-arrows are unknown. The bow is not strengthened in any way, though a ring may be placed on the thumb when drawing it. I have not seen a sling; the Sa(r)rikin Jemaa, however, assured me he had been wounded by a stone from one at Jigya: this may have been thrown from the hand, of course. Stones are not usually rolled down on the enemy, but the last British Patrol was attacked in this way. The spear has an iron head with flanges, and a small piece around the end of the butt; it also has a small projection on which to rest the forefinger. The shield is round and made of hide, bullock for preference; I believe there are some of grass, also, but did not see any.

The chief causes of war are the capture of women or else the murder of men. Feuds may last a very long time between tribes, for children of a man killed, even in battle, will keep up the vendetta. The Kagoro have not amalgamated with any tribe: in fact, although they repeatedly defeated the Kajji, they seem to have never followed up their victories nor to have deprived them of any land, though this happened indirectly, because the Kajji were too frightened to go to any farms near the frontier. I should not think that knowledge of any of the arts or culture of other tribes has come to the Kagoro through war, nor has migration been promoted by it to any great extent.

When one side is tired of the war any women who once belonged to the other tribe, but have been married to men of the tribe wishing for peace, are sent to their relatives as ambassadors, and they are naturally sacred, for they have friends on both sides. If peace is agreed upon, representatives of both tribes meet and swear friendship.

There is no general division of spoil, each keeping what he takes.

Hunting.—Notices are sent around when parties are to be formed; they are—as mentioned before—practically identical with war parties except for the fact that the chief seems to have more power than in an organised expedition. The ghosts are consulted (three days' beer-drinking), as before a war.

There are practically no large animals now in the Kagoro country, so the rat and field-mouse are the only "game." Most of the grass is burnt off during November and December, and these animals can no longer conceal themselves, fire apparently being employed more for the purpose of clearing the ground than for driving the quarry. Sometimes patches of grass (perhaps 12 ft. high) are left, and these

are trampled down, so that the inhabitants will be driven out into the open where the men are advancing in line, with their arrows fitted and bows stretched. I have twice seen hunting parties, but no "game," so I do not know if the men are good shots or not. I should think they must be though, for "hunger maketh a good marksman," and unless they could hit a target when they got the chance it would hardly be worth while looking for it.

Each party keeps to the limits of the land of its own town when hunting singly, but usually men of several villages join together. There are, I understand, no game laws, each man getting what he can, where he can, when he can. The hunts will last from early morning until sunset, and some men will be away every day from November to March. The harvest is over (October—November), the houses have been re-roofed (same time, *i.e.*, before the grass is burnt), and there is no planting until April or May, so there is nothing else to do but to "kill something."

There is only one permanent blacksmith amongst the Kagoro * (a Hausa-Filani from Dangoma). He told me that he made all his arrows of a similar pattern, so that everyone who buys from him has the same kind of missile. All, however, do not patronise their home industries, but go to Jemaan Daroro, Zangon Katab, or Moroa for them, and there are several patterns. In addition to this there is no doubt that some private marks are made: at any rate, everyone knows his own arrow. This is important, because all game belongs to him who first wounds it. Even if the wound be slight, and the beast be despatched by another, the carcase will belong to the owner of the arrow if it be still sticking in the body, for it is held that it must die eventually owing to the poison. It sometimes happens therefore that one man will pluck out the arrows of another so that there will be no proof of ownership, and this leads to quarrels and fights between the various partisans, especially if the disputants be of different towns. Men have been wounded in these miniature battles, and even killed. If there be no means of deciding to whom the beast belongs (say if it has escaped, has got rid of the arrows, and is killed by other men who did not see it wounded) the claimants will be required to go through an ordeal, or it will be divided amongst the whole party. The owner of the carcase takes it to his own house, where it is eaten by the family and relatives. He is not compelled to give any of it away, though he may ask the *meakwap* to the feast, and perhaps even the *agwam.* As with us, a man may try to purchase popularity if trying for any office. The poisoned meat does not seem to be dangerous.

I have not seen any game stalking (nor game), so do not know if they dress up to represent their quarry. The Nadu (cannibals with pierced noses to the south) do, however, and have a wooden helmet with horns to which a hide can be attached. Pits were dug for animals in the old days but not now, and there are snares for birds I am told. Dogs and horses are not used, but with the Gannawarri and Kibbo most of the members of the hunt are mounted, and they drive in a very large circle which constantly decreases, everything in sight being slaughtered and eaten. This procedure soon exhausts the game in the country; no doubt the Kagoro did the same kind of thing formerly.

The weapons are the same as for war, the arrows all have a similarly shaped head (there is no distinction for different sized animals), with only one point. Weapons are made to kill, or at any rate disable, so that the flesh may be secured; the skins are only a secondary consideration. It is no reproach from a huntsman's point of view to wound and not capture an animal, but the relatives—who would thus miss a feast—might have a word or two to say in the matter. Only men take part in hunting and fishing.

So far as I know, there is no fishing with a baited hook, but I am not certain whether small cast-nets are used or not. Fish traps are made of cane, the idea being the same as in our lobster pots, but those of the Kagoro are much longer in proportion to the breadth.

It must not be thought that the women do all the work. If the tasks be reckoned up it will be seen that each sex has an almost equal amount. The men do not work as regularly or continuously as the women, but while they are at it they undoubtedly have to expend more energy; they do all the hard work. Certainly they have chosen if not the wiser at any rate the more enjoyable part, for hunting animals gives more pleasure than searching for firewood, fighting enemies more excitement than "minding the baby." However, the division of labour must always be on much the same lines in

* The southern towns get what they want from Jemaan Daroro. The Moroa too have only one, the Kajji several. Sometimes travelling smiths visit these tribes just before the wet season, when there will be a demand for hoes.

primitive societies, for the male's superior strength and health enable and entitle him to choose his tasks. Men clear the ground for the farms because women are not strong enough, they hunt because women are not able to do so, they fight their enemies to prevent them carrying off their women. It is at this time, I suppose, that the division of labour takes place. The male is watching his enemy and his attention must not be distracted lest he be surprised, so the household duties naturally fall to the female. When he does return he is too tired to collect firewood for fuel, so *she* must. Hunting is a natural training for war, and as such, and because it is fatiguing and takes him away from the home, it falls to the man's share. Nature prevents women competing, for at certain times they would be unable to fight or hunt, and so the whole community would suffer if dependent upon them, and they would either have to bear no children so as to be free in their movements, or else be forced to take their offspring with them, and so be an easy prey to a swift enemy, and quite useless as huntresses. However, this is hardly the time to enlarge upon such a subject. Labour seems to become sharply defined into men's tasks—those to do with the protection of the home, and women's tasks—those actually in the home, and as the latter are not dangerous they are looked down upon as "women's work"; and this is true not only of members of primitive societies but even of the most advanced people, who ought to know that neither kind of work can be performed alone because they are dependent on each other.

The relations of the native to the official are usually unfriendly at first, so perhaps I ought to have described the war parties earlier; but later on better understandings arise, and I think you will agree that in this slide there is not much sign of disagreement between the people and myself.

Relations of animals to man.—The horse is not used in war or hunting. The Kagoro and Kajji have but few, the Moroa and Attakka a fair number brought from Zaria. They are about thirteen to fourteen hands high and rather weak. The bridle is made of leather sometimes ornamented with brass. There is no bit, but a toothed half-hoop of iron passes behind the animal's jaw to join a similar half-hoop above the nose, and can be tightened by a pull on a rope on the left side which forms the rein. The saddle—if any—is a goatskin tied on to the back. Some of the pagans in the district make a cut in the skin over the backbone about a foot long and open it out, so that the flesh swells up and forms a pad, which, after a time, seems to become callous. There are no mules nor donkeys.

The dog is used as food, and always forms part of the marriage gift. It is a poor specimen —I fancy only one breed, they all look the same—but since it is a cur it makes a good watch-dog, and it also acts as a scavenger.

No cattle are kept, but goats and sheep are. The flesh is the only part used for food, not the milk. Clothing is made from the skins.

There seem to be no mythical animals, but when the ancestors of the Kagoro came to the country wild beasts are said to have been numerous. I have not heard of any monsters in the water; the crocodile is present (in the Kaduna) and he is sufficient for their imagination. Some say that animals have souls, others say not: the latter seems to be the more widely accepted view. Certain names of animals are given to children, as well as those to commemorate events; *Jin*, the hedgehog, and *Zat*, the buffalo, are common, also *Kura* (the Hausa name for) the hyaena.

No animals nor birds are used for game fights, but a fowl can act as deputy for a human being in an ordeal. A fact which at first strikes one as being very strange, but which on second thoughts appears quite natural, is that animals understand only the local languages. In Amar (Muri Province) in 1906 I bought a cow from some Filani people (the great cattle-breeders of Nigeria), but could get no milk from her although she had a calf at the time, the excuse given by my servants (all Hausas) being that "the cow could *talk* only Filani," and would not give them her milk. I, of course, thought that the real reason was laziness, but on getting a Filani girl from the barracks found that the animal was quite tractable, and would give milk in plenty. The other servants caught and held the cow, so their work was not much reduced. This would not be enough by itself to prove anything, for the Filani girl knew much more about the management of cattle than the Hausa boys did, but I noticed in 1909 that dogs and horses procured in Moroa were quite at a loss when told to "Come here" or "Gee up" or "Whoa," and when we think of it, if English pets were addressed in an unknown tongue they would not comprehend, so there seems to be no doubt about the matter. After all, if the people themselves did not understand a foreigner's language, it is hardly likely that their animals would.

In concluding this paper, which, although very long, does not give anything like as complete an idea of the people as I should like to convey, I wish to express my thanks to Lieutenants Matthews and Evatt for reading over my notes and offering valuable hints, and to the Board of Anthropological Studies at Cambridge for much sympathetic help and encouragement. Not that a student, when once he has commenced "the study of man," requires very much encouragement! I defy anyone to live for any length of time amongst such primitive peoples, and not become very fond of them. He need not, in fact *must* not, spoil them; it is almost better to be too severe at first than too lenient; they appreciate a strong "Over-Chief." I managed to collect nearly three years' tribute in a little over twelve months, and yet think I was not half so unpopular as Form IV. They are rather smelly folk, certainly, and in other respects fall somewhat short of *our* standard of life, but, on the whole, one can really admire them—even though one has to fight them.

My Camp at Mersa (Kajji).

The last slide gives an idea of the beauty of some parts of the country of the Head-hunters, and I am sure you will agree that I have a good deal of excuse for being fond of it and them.

DISCUSSION.

Surgeon-General G. J. H. Evatt, C.B., in opening the discussion, thought everyone present would agree that the author had given a most searching and interesting study of Northern Nigeria. His own remarks had a certain personal element in them, because his son was a lieutenant of an English regiment which was sent out to Nigeria, where he had the good fortune to command the troops who were with the author at Jemaan Daroro. He very much wished that, during his own service in India, China, and different parts of the world, there had been somebody present who could explain the customs of the various countries which he had been in. It seemed to him a great pity that so many thousands of English soldiers went to many different countries and never heard anything of the meaning of the customs which existed therein. The author was a trained anthropologist. Instead of merely amusing himself, as some other officers did when they returned from service abroad, he at once went to Cambridge, where he studied Anthropology, and was the first to take the newly-established diploma in that subject. Through the knowledge he had thus acquired he was able to teach to the uninitiated facts which they would pass by as of no importance; and those records passed round the circle of the world and gave information with regard to the origin of things far away which otherwise would never have been dreamt of. The author had referred to the question of the sacredness of fire. The reason the Vestal Virgin was not allowed to have a sweetheart was that she was so sacred. If she passed down the street and a prisoner who was coming up the street saw her, that prisoner was at once acquitted. She was so sacred because she was the match-box of the age. The care of the fire was her sacred duty. When once the fire was lit it was not allowed to go out, because the making of fire was so important. Exactly the same sort of thing prevailed in Nigeria. His travels round the world had taught him to appreciate the fact that the study of anthropology would make foreign service infinitely more interesting than it was.

Dr. HERMANN K. W. KUMM thought it would be of great interest if the author could state whether anything was known about the language of the people he had been describing, and what relationship it bore to other languages spoken in the hill country, so that conclusions might eventually be arrived at as to whether the people belonged to the Bantu family, or whether there was any relation between the Hamitic races and the tribes of head-hunters of Northern Nigeria.

Mr. T. C. HODSON said that he had served as an officer on the Indian frontier, where head-hunting was in full swing ten years ago, and there seemed to be something of a comparison on anthropological grounds between head-hunting in Nigeria and head-hunting in Assam. In the first place, head-hunting in Nigeria was stated to be something in the nature of a mark in social evolution, *i.e.*, a young man showed his fitness for marriage by producing a head. Davis, in the Assam census report for 1901, pointed out that that was exactly the cause of the head-hunting in that country. Nowadays many a young Naga was unwedded because the authorities had rigorously put down head-hunting. Another cause of head-hunting was the vendetta pure and simple. No feud could be allowed to rest until the arithmetical tally of heads was exactly equal on either side. He remembered on one occasion visiting a big village of eighty houses, and insisting on the exchange of all the heads between that village and the neighbouring village with which he was endeavouring to make peace. The exchange of heads was quite an interesting function, some of the heads having been kept for over twenty years. Records existed which showed that that particular village had been burned twenty-two years before, and all the heads destroyed by the fire, and in the course of twenty-two years something like 400 heads were obtained, all of which were duly returned. In another case he found that head-hunting was practised as a rite precedent to the cultivation of the fields, it being necessary to cut the head off the body and show the head to the fields so that the fields might be prosperous in the coming year. A similar feature existed in the Trieteric festivals of early Greece. Another interesting point was the taboo placed on the occupations practised by women when they went to a strange tribe. He remembered going to a strange village where weaving was not a special industry, and found that a woman who had come from one of the weaving villages was not allowed to practise her craft for the reason that the villagers feared the magic of the craftsman. In those villages each small group tended to practise one special or localised industry. One village made mats, another had a weaving industry, while others had a monopoly of iron manufacture. The beginnings were thus seen of the caste system, so far as its economic development was concerned. One feature of the paper which was particularly interesting was that head-hunting was not divorced from the mass of customs in which it was found. It was very common to hear papers read in which one custom was wrenched apart from its context, whereas it had its real value only in reference to its context. That was the great lesson that scientific anthropology was teaching, that the customs of natives must be looked upon as a whole.

Major LYLE CUMMINS, R.A.M.C., said he understood from the author that the incision marks on the chests of the women were made when they were married, and not at a particular epoch in their lives. He noticed from one of the photographs that the incision marks on the forehead of the men were very similar to the marks he had seen among the Dinka tribes. There the marks ran horizontally instead of vertically, but they marked a distinct epoch in the life of the young male, being put on the head of the Dinka when he attained manhood. He would be very interested to know whether, among the male head-hunters, the incisions were put on at a definite epoch. Reference had also been made to the question of the use of native beer as compared with English gin. In the Sudan, native beer was consumed in enormous quantities, and drunkenness caused by it was very frequent, but it lasted a very short time. The natives got drunk very quickly, but were sober again in a couple of hours. Drunkenness was quite a daily occurrence among the natives who could afford it, and it seemed to have little effect on their health. As a medical man, he had been struck by the fact that it apparently did them so little harm. It would be of interest if the author could state whether he knew how much alcohol was contained in the native Nigerian beer. His own impression was that European spirits were much more harmful to the health of the inhabitants of the Sudan than native grain beers. Definite information on that point would be of great medical interest as well as of economic interest to those who administered native races.

Captain TREMEARNE, after thanking Surgeon-General Evatt for the kind remarks he had made, stated, in reply to Dr. Kumm, that he started to learn the language, but nobody else had learned any of it yet. He was afraid, therefore, sufficient material had not been obtained to understand much about it. As a matter of fact he did not get into the grammar of the language. He had made a vocabulary, which had been deposited in the Cambridge University Library, and could say a few sentences, but that was all. He had been interested to hear that several of the customs in Assam were the same as those prevailing in Nigeria, and he had mentioned in the paper that Dr. Haddon had found the same sort of thing existing in New Guinea. The heads obtained were kept and hung up outside the roofs, generally under the thatch. While he was in Nigeria, in March 1909, there was a great beer-drinking festival, during which

a cannibal tribe, the Gannawarri, sent some representatives to visit the Moroa; and during the festivities five of the men were shut up in a house, killed and their heads cut off. War was threatened, and he had to try and stop it. He thought the only way to do so was to get the heads back, although the Gannawarri did not seem to want them very particularly; but as a matter of fact he did get them back, and they were now in the Cambridge Museum. Mr. Hodson had mentioned that the Nagas cut off the head from the body to show the fields in order that there might be a prosperous agricultural season. The Kagoro sacrificed a fowl, and it was quite probable that they might have sacrificed a human being earlier in their history. With regard to scarification, the men and women had the same marks on the head, but in regard to the body it was different. It was voluntary for the males to have marks on the body, but the females must do so. The chests and backs of girls were scarified, and when they were married the foreheads also. With regard to the question of native beer and European spirits, his opinion was founded on the report of the committee which inquired into the question of alcoholic drinks in Southern Nigeria about two years ago. Much the same beer was made in Southern Nigeria as in Northern Nigeria, and if it was worse there than the English article it was probably worse in Northern Nigeria also. A great outcry had been made against the importation of gin, but he did not see how the importation could be stopped. There was a great amount of it going into Northern Nigeria, although officially they did not know it, but they might just as well recognise it officially and get revenue from it. Sir Harry Johnston had said that the use of that much despised form of alcohol, trade gin, in Liberia, as in other parts of West Africa, seemed to be much more misunderstood than anything else. In fact, in many parts of Southern Nigeria gin was never drunk at all; it was simply used as currency. If it was admitted into Northern Nigeria, although some of it would of course be drunk, a great part of it would probably be used for trading purposes. He did not think it would do much harm, and the Government would obtain revenue, which it badly needed.

The CHAIRMAN, in proposing a hearty vote of thanks to the author for his paper, said he remembered that an old friend of his, General Lobley, used to take a great interest in the subject, and wrote a book called "The Head-Hunters of Borneo." He used occasionally to call upon him (the Chairman) with a black leather bag in his hand, from which he used to abstract a human head, the merits of which he would explain, and he remembered General Lobley telling him that such heads were very often taken by a young man in order to ingratiate himself with the fair sex. He congratulated the author upon the musical talent he had displayed. It was a very unusual occurrence to have a lecture in the historic hall of the Society accompanied by music, and when the author was playing the quaint native dances, he felt quite sorry that some of the ladies who were depicted in the slides were not present to show how the dancing was performed.

The vote of thanks was then put and carried, and the meeting terminated.

EIGHTH ORDINARY MEETING.

REPORT OF THE DISCUSSION ON THE PAPER ON

EXAMINATIONS IN THEIR BEARING ON NATIONAL EFFICIENCY.

By P. J. HARTOG, M.A., B.Sc.

(*Continued from p.* 291 *of the* Journal *of February* 3, 1911.)

Dr. H. A. MIERS, F.R.S., Principal of the University of London, thought that, whatever change was made in the examination system of the country, it was necessary not to forget a certain part played by competitive examinations at the present time. One of the chief functions of education was to stimulate people to work for themselves and not merely to receive from others. There was a vast number of students, both at schools and universities, who had no desire to learn, and therefore required some stimulus to urge them to teach themselves. If the examination stimulus was removed, bad as it might be in some respects, it might be necessary to replace it by some other stimulus for the sake of the less willing students. With regard to the question of examinations as a test of general capacity or general intelligence, he was very much struck with a paper read at the Sheffield meeting of the British Association by a gentleman who visited a school where the boys were being examined for scholarships, and who obtained permission to apply his own tests in order that he might compare the list of passes according to his tests with those given by the ordinary scholarship examination. He made a sporting offer that if any boy obtained a scholarship by the one test and did not gain it according to the other, he would pay the scholarship fees. He applied the usual intelligence tests, with the result that his list was absolutely identical with the list obtained by the ordinary scholarship examination method. From that a conclusion might be drawn that it did not much matter in which subjects the boys were examined, and doubt might arise whether as a test of general capacity the particular examination method or subject was of very great importance. He wished, however, on the present occasion to endorse the conclusion of the author, that the need had arisen for an inquiry into the present methods and systems of examinations—as to whether they were adapted to the purposes they were supposed to fulfil. In view of the figures quoted by the author, which were very far from complete; of the enormous amount of time and

money spent upon examinations in England at the present time; of the large number of poor teachers who were inadequately paid for teaching and were driven to supplement their income by examining (the question could well be asked whether the money might not be better spent in paying them more for their teaching); the time was ripe for inquiring whether that vast expenditure of time and money was being utilised in the best posible way and leading to the best possible results, and he trusted that one of the results of the paper would be that an exhaustive inquiry would be made into the present examination methods of the country.

Professor JOHN ADAMS desired, as a teacher of teachers, to emphasise the teaching function of examinations. Anyone acquainted with the teaching of students knew that part of their work in preparation for teaching was to be able to set an examination paper, and to that extent, therefore, students were taught how to examine. The point that struck him most in the paper was the admirable selection of points of view chosen by the author. He wished to emphasise the difficulty of interviewing mentioned in the paper. He had just come from interviewing 150 students for selection for his own college, and it had given him the greatest possible anxiety to determine which of those students to choose, owing to the very different qualities of the students presented. The examination those students had to pass might be good, bad, or indifferent, but it showed whether or not they were good at passing examinations, and the main element he had to consider was whether a student coming to the college would be able to pass another examination three years hence. He had no doubt whatever that he could manipulate his students for examinations, as he had known students manipulate examiners. He remembered one student who was being examined, pretending that he did not know the difference between sulphate of copper and sulphate of iron, in order that the professor who was examining him might not question him further in regard to iron, on which subject, however, he had been specialising. That sort of thing was done all round, and had to be taken into account in connection with examinations. He had certain very firm convictions with regard to the capacity-test as compared with the knowledge-test. The knowledge-test acted as a sort of false function with regard to pupils. As an examiner, he laid it down as a universal rule to "pluck" a man in every case where he had not the requisite knowledge of the prescribed books, whatever his abilities were. Examiners were appointed in those circumstances to determine whether the student had done the work which the examiners had to test. On the other hand, there were particular examinations in which that process might be reversed. He contended that a boy should be examined in English literature, not in a room bare of books, but in a library; and that a boy should be examined in geography, not in a room in which the maps were turned to the wall, but with an atlas by his side and as many maps as he could use, because he had found that a boy who did not know where to look for things was absolutely hopeless. He had known a man go into an examination with every proposition of Euclid hidden about different parts of his person, and come out "plucked" because he could not find the place. In conclusion, he heartily supported the author's recommendation that an inquiry should be held for the purpose of throwing more light on a subject on which so much difference of opinion existed.

Dr. A. C. HEADLAM, Principal of King's College, London, said the result of his large experience of examining was that there were certain examinations, within certain limits, in which the result might be fairly satisfactory and the effect not unwholesome. Those were examinations conducted, in the first place, by a board of persons acting together, who not only marked the papers but talked over the papers with one another. In the second place, the great majority of the members of that board were the teachers of the persons being examined; and, in the third place, they were able to supplement, not necessarily in every case, any literary examination by means of *viva-voce* examination. With those three conditions the result, for the particular purpose in view, would be fairly satisfactory. But of course it was necessary always to consider what the purpose in view was. It was his experience that if six examiners looked over the papers and compared their results, in quite ninety cases out of 100 they would find their results coincided, if they were fairly capable and suitable examiners. In 10 per cent. of the cases, however, very great discrepancies would occur, which necessitated not only re-reading the papers, but discussing them very carefully. The individuality of the person taught, or some similar reason, was the general cause of that great discrepancy; but with a board working together the result was generally fairly satisfactory. That meant that an internal system of examination should be aimed at. The fundamental point under consideration was how to get good men for the public services under those conditions. When Lord Cromer was selecting men for the Sudan, the first point he laid down was that they were to be university men, *i.e.*, that they had gone through a certain necessary system of training in life. Looking into the future, it seemed to him the main principle which would have to be adopted was either selection out of a carefully-selected body of candidates, or the examination of a selected body of candidates. It would be necessary to lay down that all the candidates for a certain post must be persons who had been through the university and obtained certain marks of distinction, and a certain number of those would be selected or examined. In a similar way, for certain other appointments, it would be necessary that a certain number of years should be passed at a recognised public school, care being taken that the

educational system provided facilities for everybody. In that way, what he might call the tyranny of the external examination system would be abolished. He remembered Mr. Gladstone once saying there was one thing which must be remembered in connection with examinations, namely, that a person was compelled for a certain number of hours to learn—to concentrate his mind on certain points. That taught men the valuable habit of concentration, and therefore he thought internal examinations were very valuable if carried out under proper conditions. Personally, looking back on his own career, he did not feel that examinations had done him any harm; but, looking back at the career of a number of other people who had been prepared specially for external pass examinations, the result seemed to have been in their case to make them have no interest in learning or in intellectual pursuits at all, but to make them regard learning as only aimed at passing examinations. It was more in relation to the parents that the examination system was bad. There were many parents at the present time who looked upon schools as merely places to prepare their children for examinations in order to get posts. That, unfortunately, was the result of the excessive examination system in the country. He did not know what the Chairman wished the audience to draw from the small autobiographical account he had given, but it seemed to him (Principal Headlam) to suggest that there was a good deal to be said for authorities being able to interfere, even with a medical examination!

Professor Arthur Schuster, F.R.S., said he could not point to any part of the paper with which he was not in agreement. The problem, however, was to find some way of making progress, because people had been saying most of the things said by the author for a good many years, but nevertheless matters were no better now than they were ten or twenty years ago. The paper and the discussion had made a little clearer to his mind than had been the case previously, that a sharp distinction must be drawn between the examination requirements for academic purposes and the requirements of selection for the public services. In the public services a certain amount of competition could not be avoided. A definite number of vacancies existed, which must be filled in some way or other by selection or competition. But in a university examination it was only necessary to decide whether a man was fit for distinction or not, as the educational authorities were not compelled to confine their awards to a fixed number of men. The great subsequent difficulty in the public services did not seem to him to be so much to select an efficient person, as to get rid of the incompetent person when the examiners had made a mistake. There was no country that gave so much consideration to the incompetent man as this country. Even in the universities the teachers were entreated to have regard to the weak students, the students who did not want to learn, and more or less to neglect the competent man in consequence. In regard to the actual power of examinations to test, he had never had any fear that a certain definite standard could not be maintained. He had had a good deal of experience in one limited subject in which he never had a large number of students to examine, but it was quite surprising how near different examiners got in marking the same papers. He was certain, however, there were very great differences very often in the standard of pass from one year to the next. The ingenious and acute remark was made to him by the late Dr. John Hopkinson, after he had been serving a term of office as an examiner for the old London University, that he was quite sure the right way to conduct an examination, where there were at least one hundred students, was not to fix the standard by a minimum number of marks for a pass, but to "plough" a fixed percentage of the students every year, because the standard of the papers was much more likely to vary than the standard of the candidates. He would have liked to discuss in detail the question of the competition which was introduced very often into university examinations. It had been thought that some of that competition had been got rid of by abolishing the order of merit and simply substituting classes, but in some respects this had made the matter worse. It was a serious matter whether a man obtained a first or a second-class. A man who was really quite safe to get a first-class was so afraid that he might only get a second, and his career might be ruined in consequence, that he devoted his whole time, which might be more usefully occupied, to making sure of getting his first-class. He had recently spent some time in India, where he had studied university questions. The university examination system had been imported from this country into India, and it was having the most disastrous effects there; and he was quite certain that the whole educational system of India required reconsideration from that very point of view.

On the motion of the Chairman, a vote of thanks was accorded to Mr. Hartog for his paper, and the meeting terminated.

HOME INDUSTRIES.

Port of London Improvements. — The Port Authority was established mainly for the purpose of improving the dock accommodation of London, of bringing it up to the requirements of the greatest of existing ports. In this direction London has not kept quite abreast of the times. Huge sums have been spent by the State and Municipality in the improvement of the docks at Hamburg, Antwerp, and elsewhere. In London, competing interests and conflicting authorities delayed improvements admitted to be imperative if she was to hold her own as the first of ports. The Tilbury Dock was opened a quarter of a century ago;

since then there has been no great dock improvement, and since 1886 nothing has been undertaken in the Port of London to meet the continually increasing size of vessels. How enormously size has increased is very clearly shown in the memorandum just issued, in which Mr. F. Palmer, Chief Engineer to the Port Authority, explains the scheme for improving and extending the dock accommodation of the port. Since 1886 the increase in the average size of the largest vessels represents a growth in length from 450 feet to 700 feet, or 55 per cent.; in beam from 52 feet to 77 feet, or 48 per cent.; in draught from 28 feet to 35 feet, or 25 per cent., and in gross tonnage from 7,000 to 24,500, or 350 per cent., whilst the volume of shipping using the Port of London has grown from a net register tonnage of under 12 millions to over 18 millions. The Port Authority now recommends improvements and extensions estimated to cost 14½ millions, but it is not proposed to incur the main portion of this expenditure immediately. Lord Devonport divides the projected works into (1) primary or urgent; (2) secondary; (3) contingent. The estimated cost of the work to be set in hand immediately—assuming Parliament assents—is put at rather less than £4,000,000. This would provide a great extension of the accommodation available at the London at Wapping, the West India and Millwall in the Isle of Dogs, and the Victoria and Albert group lower down. Nothing is to be done on the south side. The Surrey Commercial Docks have in the Greenland the most recently-constructed dock on the Thames, and meet present requirements. It is proposed to build an entirely new Albert Dock, to be called the South Albert, parallel with the existing one, and between it and the river, with new entrance lock, dry dock, quays, and sheds complete. It is estimated that this will cost 2½ millions. About a million is to be spent on the West India Docks, where there will be a new entrance from the river, with a new basin and quays, new dry dock, and many internal improvements. At the London Docks it is proposed that the entrance be reconstructed, and there will be a large increase in quay accommodation. Later on there is to be a new and very large dock on the north side of the existing Albert Dock, which will cost over 4 millions; extensive additions at Tilbury, and improvements at the Albert and Victoria Docks, the East India, and the Millwall. In preparing the scheme which has now received the final sanction of the Port Authority, Mr. Palmer took the fullest possible advantage of gathering information from sources competent to give good advice and guidance, from men like Sir William White, Lord Pirrie, Sir Thomas Sutherland, and Sir John Ellerman, with the result that he is able to say the leading shipping interests think well of his scheme. It is not to be supposed that its details and estimates will not have to meet close scrutiny and sharp criticism. Close and careful independent examination is necessary, but it may be taken that in its main conceptions the scheme will prove acceptable to Parliament. If adopted, leeway will soon be made up, and future needs sagaciously provided for.

Land Values.—There has been some discussion, prompted by Mr. Walter Long's decision to sell a portion of his Wiltshire property, as to whether such sales of land are likely to add to the seller's income, and although experts differ as to what the average selling price is, it seems pretty clear that where estates are moderately rented the large landowner is likely to increase his income materially by selling a substantial portion of his property. Assuming that an owner can sell at twenty-five years' purchase on the net rents, and that he can reinvest at 4 per cent, he will benefit considerably by a sale. Of course there is a great difference between twenty-five years' purchase on the rents, after deducting tithe and land tax, as compared with a net return after allowing not only for tithe and land tax, but also management, repairs, insurance, rates payable on cottages, village property, etc. Mr. Howard Frank, who is able to draw upon a wide experience of land sales, says the owners who have sold during the last two years have in every instance benefited financially, after allowing for all costs of sale, and he tells us that the estates he sold during last season realised an average of twenty-seven years' purchase upon the existing rents, after deducting tithe and land tax, but not on the gross rents. This is a sufficient indication that in the majority of cases rents were low. It would seem, therefore, that owners who have decided to realise a portion of their estates, reinvesting the moneys in securities that can be sold more readily as occasion arises, are acting prudently, more especially having regard to the tendency of modern legislation and the rate of the death duties. Whether the tenants will be generally benefited is not so certain as many take it to be. Indeed, so far as the old-fashioned landlords are concerned, the men who do not exact a rack rent, and do not dream of disturbing a tenant if he does his duty by the land, tenants must often be prejudiced by the present tendency to sell. The majority of tenants cannot afford to purchase their farms, for their means are not enough to allow them to buy the land and stock it. On the other hand, it is hard that the land should be sold over their heads and get into speculators' hands when, as under the Irish Encumbered Estates Act, either the tenant has to pay an increased rent or be turned out.

Atmosphere in Gassing-rooms.—A writer in the *Manchester Guardian* suggests that advantage might more frequently be taken of the very efficient appliances available for the improvement of the atmosphere in gassing-rooms. There is probably no process in cotton spinning or manufacturing which involves more discomfort to operatives than is occasioned by the vitiated atmosphere generally experienced in these rooms, and ventilation by means of fans placed in the ordinary way either in the roof or walls of the rooms is very inadequate.

Several effective devices are available. In one of these the gas-jets are enclosed in vertical shields which are connected to metal trunks, the latter being exhausted at the outside by means of fans. This appliance has been fitted in gassing-frames in several new mills in Lancashire and Yorkshire, and the rooms are quite free from obnoxious fumes. Another device consists of a duct attached under each machine and connected by trunks to fans which are fixed in the roof. It is to be regretted that many of the older mills are slow to adopt such appliances as these. In many cases the additional expense can hardly be a consideration, and probably would be more than compensated by increased efficiency in operatives resulting from improved working conditions.

The Outlook for Coal.—There has been no abnormal demand for Welsh coal. The aggregate trade is slightly heavier than the average of last year, that is all. And yet colliery owners are quoting for supplies over the next three months at from 9*d.* to 1*s.* per ton above the figures quoted two or three months ago, and for the six or nine months at an average over their December prices of 6*d.* to 9*d.* per ton. Two reasons are given for the upward movement apart from the usual holiday pressure and the practice of merchants to close their commitments with the colliery companies—the cessation of work in the Rhondda and Aberdare Valleys, and the restrictive influence on production of the Eight Hours Act. The trouble in the Valleys reduced the output during November and December by something approaching 50,000 tons per day. The consequent congestion would have been relieved much earlier but for the effect of the Eight Hours Act. Immediately there was a market in which the prompt demand has to some extent exceeded the supply, the hampering effect of the Act was felt. The collieries have failed to expand their outputs as was the custom before the Act came into operation. In many of them the production is from 10 to 16 per cent. lower than it used to be, and the new workings have not been developed sufficiently to make up for the difference. It is estimated that labour legislation has added at least 2*s.* per ton to the cost of coal since 1842, which means, with the present output, £26,000,000 a year. But most of this was incurred in better safeguarding the miner at his work, and so is not begrudged. No part of the additional cost of coal to be attributed to the Eight Hours Act increases his security; on the contrary the weeding out of the elderly and experienced miner, and the hustling, which are the direct consequences of that Act, must tend to make mining accidents more frequent.

The Declaration of London. — Almost all the Chambers of Commerce and shipowners' organisations throughout the country are protesting against the ratification of the Declaration of London. The chief objections to it, from the British point of view, are concisely put in a resolution recently passed by the Swansea Chamber of Commerce. It objects on the following grounds:

"1. The effect of the Declaration is to change, in an entirely unprecedented manner, the law of nations as hitherto maintained, and to introduce a code, which, in its effect so far as the regulation of our naval operations is concerned, would be highly prejudicial to this country.

"2. The wide discretionary right which the Declaration gives to foreign naval commanders to capture and destroy cargoes of foodstuffs in neutral vessels destined for this country when a belligerent, lays the oversea food supplies of this country open to alarming contingencies, the dangerous effect of which must not be under-estimated.

"3. The absence of any reference in the Declaration restricting the conversion of merchant vessels into warships on the high seas, and the determined opposition with which our delegates at the Naval Conference, in their efforts to arrive at an understanding on this point was met, makes the matter of such crucial importance as to warrant the abandonment of the treaty."

It is less probable than it was that the Cabinet will seek to ratify the Declaration as it stands. Much will depend upon the view of the Imperial Conference, which will consider it in May.

New Insurance Companies.—Last year twenty-nine insurance companies were registered, with an authorised capital amounting to £1,284,000, as against sixty companies in 1909, with an aggregate authorised capital of £4,250,000. Most of the flotations in 1910 were of small importance, and of the total authorised capital raised, three companies —the Gresham Fire and Accident, the Royal London Auxiliary, and the London County Commercial—were responsible for £1,250,000, or about 97 per cent. of the whole.

NOTES ON BOOKS.

THE DEVELOPMENT OF THE TELEPHONE IN EUROPE. By Herbert Laws Webb. London: Electrical Press, Ltd.

Mr. Webb has republished in book form a series of articles on this subject which appeared last year in *Electrical Industries*, and has prefixed to them a short introduction by Mr. Harold Cox. Mr. Cox states briefly, but forcibly, the arguments against the purchase and working of telegraphs by the State, and shows that a commercial undertaking, which in other countries, notably in the United States, has paid handsome dividends, and one which, while in private hands in this country, was being developed economically and profitably, has not only failed to provide revenue, but has proved a source of considerable expenditure to the State.

Mr. Webb himself gives a very full account of the origin, evolution, and development of the telephone. While he draws very unfavourable conclusions as to the comparative results achieved

in America and this country, he also shows that Great Britain is not really much behind other European countries, which have suffered more or less from the same causes as those which have prevented the complete development of the telephone in this country.

The Arts and Crafts of Our Teutonic Forefathers. By G. Baldwin Brown, M.A. London: T. N. Foulis.

The substance of this book was delivered as a course of Rhind Lectures before the Society of Antiquaries of Scotland last year. Professor Brown's object is to prove that there is a genuine and original Teutonic art born and developed amongst the different branches of the Teutonic race, Goths, Burgundians, Franks, Angles, Saxons, Lombards, etc., and that it was not in any way due to Roman influence. This thesis he supports by an examination of the various works of art of Teutonic origin which have come down to our own times. The bulk of these are personal ornaments, or arms and armour, derived from graves, together with sepulchral urns, etc. There are also a few objects which have been preserved in churches and elsewhere, and still fewer monuments.

The book is illustrated with a very large number of photographs, but they suffer from their very small size, and their reproduction leaves something to be desired.

GENERAL NOTES.

Departmental Committees on Lead Poisoning amongst Painters.—The Home Secretary has appointed two departmental committees to investigate the danger attendant on the use of lead paints and compounds to persons engaged in painting buildings and to persons engaged in painting carriages and coaches. The chairman of both committees is Sir Ernest Hatch, Bart.; Sir Godfrey Baring, Bart., Lord Henry Bentinck, M.P., and Mr. E. L. Collis, Medical Inspector of Factories, are members of both committees. The other members of the committee on the painting of buildings are:—Mr. F. G. Rice, President of the London Master Builders' Association and Representative of the National Federation of Building Trade Employers; Mr. W. G. Sutherland, Secretary of the National Association of Master Painters and Decorators; Mr. Archibald Gardner, Secretary of the Scottish Society of House and Ship Painters; Mr. J. Parsonage, Secretary of the National Amalgamated Society of Operative House and Ship Painters and Decorators; and of the committee on the painting of carriages and coaches, Mr. A. L. C. Fell, Chief Officer of the London County Council Tramways; Mr. C. L. Mason, Works Manager of the London and North-Western Railway Company's works at Wolverton; Mr. Charles Kinggate, Secretary of the United Kingdom Society of Coach Makers; Mr. W. Robins, Member of the United Kingdom Society of Coach Makers. Communications may be addressed to the chairman at the Home Office.

Turin International Exhibition, 1911.—In the British Section of the approaching Turin Exhibition, chemical and physical apparatus will be shown, as far as possible, as it would be used in a laboratory. There will be on view at least two well-equipped chemical laboratories, with such work going on as will effectively illustrate various interesting processes. There will also be a large space available for the display in show-cases of chemical products and apparatus not in use in the laboratories, and smaller rooms will be provided for certain special appliances. The court devoted to scientific instruments will be of similar design. Here, also, arrangements are being made for the display of apparatus ready for work, electric supply, where needed, being provided. The equipment of a large dark room is under consideration, and in this, projection apparatus, such as oscillographs, spectroscopes, optical lanterns and photometers, could be shown to advantage.

Abnormal Places in Mines. — The Miners' Federation of Great Britain recently convened a national conference in London to consider the question of "abnormal places" in mines. In many districts throughout the kingdom miners complain of the existence of these abnormal places. By this they mean working places where the coal-getting is rendered difficult and unprofitable by reason mainly of the large proportion of refuse that has to be cleared away. It is obvious that where men are paid so much per ton of coal, every hour taken up with clearing refuse is, from their point of view, an hour wasted. For this reason special price-lists are struck for working such places, and the adjustment of price to place often leads to friction between employers and employed. The question formed one of the points in dispute when the Conciliation Board Agreement was being drafted in South Wales last spring, and it was found to be so difficult to adjust that it was agreed to leave it in abeyance and exclude it from the provisions of the Agreement. It was the friction concerning the price-list for working the Bute seam in some of the Rhondda Valley pits that led to the strike of the 12,000 men of the Cambrian Combine.

A New Mexican Fibre.—The discovery of a henequen plant in Chiapas, equalling, if not surpassing, that grown in any henequen-producing country, has been reported in Mexico. The leaf of the new plant is from five to six feet in length in its full growth. The fibre after examination, as compared with the Yucatan leaf, has proved itself superior in its tensile properties, colour and natural length of fibre. The plant in question is not the plant lately discovered near Tuxtla

Gutierrez, and named "non plus ultra" by its discoverer, Espatoline Moguel, who claims to have found it in a village not far from that place. Present indications are that it will not be many years before the State of Chiapas will be one of the foremost henequen producing districts of Mexico, and that it will be able to grow the plant at prices which will compete with the Yucatan product. The valley of Zintalapa is particularly suited to the cultivation of henequen. In this valley there are large plantations producing henequen of an average quality, most of which are fairly successful from a financial point of view. The United States Consul at Tapachula says that it is apparent that the plants and mechanical equipment for working the henequen are run in primitive fashion, and that anyone taking the matter up seriously could be assured of a financial success. Labour in Chiapas is more than plentiful, and low in cost; and properties having perfect titles are obtainable at comparatively low figures. Not only is there a profitable field in Chiapas for the cultivation of the plant, but there is also a field for the introduction of henequen machinery.

Rubber Auctions in Ceylon.—On November 4th, 1910, the first rubber auction was held in Ceylon. A quarter of a century ago—and well within the memory of many colonists still resident and retired—the first public sale of tea was held in Colombo, and those who have witnessed the development of the tea sale will not be inclined to minimise the importance of the opening of the rubber auctions. The quantity offered at the first sale was twenty-two tons. The chief factor which has led to the inauguration of the rubber sales is the convenient position of Colombo in relation to the large consuming countries. Buyers in these countries already find it convenient to come direct to Colombo for their supplies. Public sales of rubber will be conducted weekly, it is said by the American Consul at Colombo, and it is anticipated that the new departure will meet with the same success as has attended the tea auctions. There are at present 12,000 bearing acres of rubber in Ceylon, while 185,000 acres have been planted. It has been estimated that 220,000 acres will be the maximum area planted with rubber in Ceylon, and that with 140 trees to the acre and one pound and a-half yield per annum, this will give an export of 20,000 tons by 1920. The 1909 exports amounted to 681 tons.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

February 15.—George A. Stephen, "Modern Machine Book-binding." John Murray, J.P., D.L., F.S.A., will preside.

February 22.—Professor J. Wertheimer, B.Sc., B.A., "Water-Finders."

March 1.—Dr. Leonard Hill, F.R.S., "Caisson Sickness and Compressed Air."

March 8.—James Cantlie, M.A., M.B., C.M., D.P.H., "Plague and its Dissemination." Sir Shirley Forster Murphy, M.R.C.S., will preside.

Wednesday afternoon, at 4.30 o'clock:—

March 15.—Colonel Charles Edward Cassal, V.D., F.I.C., "The Adulteration of Food." The Right Hon. the Lord Mayor of London will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

March 16.—Claude Hamilton Archer Hill, I.C.S., C.S.I., C.I.E., "Education in India."

April 27.—Sir Thomas Henry Holland, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord Avebury, D.C.L., LL.D., F.R.S., will preside.

May 25.—W. R. H. Merk, I.C.S., C.S.I., LL.D. "The N.W.F. Province of India."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

February 28.—The Hon. Sir Richard Solomon, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "The Resources and Problems of the Union of South Africa."

April 4.—Captain R. Muirhead Collins, C.M.G., "Australia and her Resources."

May 9.—F. Williams Taylor, "Canadian Banking."

Cantor Lectures.

Monday Evenings, at 8 o'clock:—

Professor Adrian J. Brown, M.Sc., "Brewing and Modern Science." Four Lectures.

Syllabus.

Lecture II.—February 13. — "Malting." Constitution of the Barleycorn — Character of Changes during Germination—Investigations of the Biochemistry of Germination—The Barleycorn a highly-specialised seed, etc.

Lecture III.—February 20.—"The Mashing Process." The Chemistry of Starch and its Transformation Products—Protein Changes during the Mashing Process.

Lecture IV.—February 27.—"The Fermentation Process." Previous Treatment of the subject by Dr. G. Salamon in 1888—The Pure Yeast Question in Brewing—Zymase and Modern Views of Alcoholic Fermentation—Nitrogen Assimilation—The so-called "secondary" products of Fermentation, etc.—Conclusion.

Professor J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

March 6, 13, 20, 27.

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

Dates to be hereafter announced:—

FRANK M. ANDREWS, "Architecture in America."

ARTHUR CHARLES DAVIS, F.C.S., Assoc.Inst.C.E., "The Manufacture and Testing of Portland Cement."

CYRIL DAVENPORT, "Illuminated Manuscripts."

GEORGE B. HEMING, "Art Education in Jewellery and Goldsmithing."

Professor RAOUL PICTET, "Les Basses Températures."

Sir WILLIAM ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

HAL WILLIAMS, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

NOEL HEATON, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 13...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor Adrian J. Brown, "Brewing and Modern Science." (Lecture II.)

Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Mr. G. Cecil Jones, "The Purchase of Fuel on Specifications."

Surveyors, 12, Great George-street, S.W., 7 p.m. (Junior Meeting.) Mr. G. G. Symons, "Land Banks and Co-operative Credit Societies."

Geographical, Burlington-gardens, W., 8.30 p.m. Major P. H. Fawcett, "Further Explorations in Bolivia."

British Architects, 9, Conduit-street, W., 8 p.m. Messrs. P. Waterhouse, J. W. Simpson, and E. A. Rickards, "The Artistic Development of London."

Mechanical Engineers, Storey's Gate, Westminster, S.W., 8 p.m. (Graduates' Lecture.) Captain H. R. Sankey, "Wireless Telegraphy."

TUESDAY, FEBRUARY 14... Aeronautical, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. 1. Mr. F. H. Page, "The Pressure on Planes and Curves." 2. Professor G. H. Bryan, "A Note on the Turning Movement of Aeroplanes."

Asiatic, 22, Albemarle-street, W., 4 p.m. Sir Charles J. Lyall, "'Abid of Asad, an ancient Arabian Poet,' with some specimens of translation."

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. W. Mott, "Heredity." (Lecture V.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. W. J. Wilgus' paper, "The Detroit River Tunnel, between Detroit, Michigan, and Windsor, Canada." 2. Mr. W. T. Douglass, "Coast-Erosion."

Photographic, 35, Russell-square, W.C., 8 p.m. Annual General Meeting.

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Mr. Ellis T. Powell, "The Industrial Development of Canada."

WEDNESDAY, FEBRUARY 15...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. G. A. Stephen, "Modern Machine Bookbinding."

Meteorological, 25, Great George-street, S.W., 7.30 p.m. 1. Messrs. R. Cooke and S. C. Russell, "Variation of the Depth of Water in a Well at Detling, Maidstone, compared with the Rainfall, 1885-1909." 2. Mr. A. W. Clayden, "The Actinograph; an Instrument for recording changes in Radiation." 3. Mr. K. M. Clark, "New Cloudiness Charts for the United States."

Automobile Engineers, at the Institution of Mechanical Engineers, Storey's Gate, S.W., 8 p.m. 1. "Report of the Horse-Power Formula Committee," with a Note by Mr. Dugald Clerk. 2. Mr. G. A. Burls, "A Proposal for a Maximum Power Rating Formula."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. E. M. Nelson, "On some New Objectives and Eye-Pieces by R. Winkel, of Göttingen." 2. Messrs. Edward Heron-Allen and Arthur Earland, "On the Recent and Fossil Foraminifera of the Shore-sands of Selsey Bill, Sussex. Addendum."

United Service Institution, Whitehall, S.W., 3 p.m. Major C. D. Simonds, "With the Anglo-French Niger-Chad Boundary Commission."

THURSDAY, FEBRUARY 16...Illuminating Engineers, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Discussion on School Lighting, with papers by Dr. J. Kerr and Dr. N. Bishop Harman.

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m.

Geographical, 1, Savile-row, W., 5 p.m. Professor Edgeworth David, "Some Antarctic Problems."

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. H. Davies and F. S. Kipping, "Different Methods of Applying the Grignard Reagents." 2. Messrs. F. B. Thole and J. F. Royal Institution, Albemarle-street, W., 3 p.m. Dr. P. Chalmers Mitchell, "Problems of Animals in Captivity." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. S. Nathan, "History of Three Centuries told by Roman Coins."

Philatelic, 4, Southampton-row, W.C., 6 p.m. "Notes on the Stamps of Roumania."

FRIDAY, FEBRUARY 17... Royal Institution, Albemarle-street, W., 9 p.m. Professor H. E. Armstrong, "The Stimulation of Digestive Activity."

Engineers, Junior Institution of, at the United Service Institution, Whitehall, S.W., 7.30 p.m. Mr. B. Bylander, "The Architectural and Engineering Features of the Royal Automobile Club Building."

Geological, Burlington House, W., 3 p.m. Annual General Meeting.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. James Swinburne, "The Uses of Chemistry in Engineering." (Lecture I.)

Mechanical Engineers, Storey's Gate, Westminster, S.W., 8 p.m. Discussion on Messrs. W. Dixon and G. H. Baxter's paper, "Modern Electrical Dock-Equipment, with Special Reference to Electrically-Operated Coal-Hoists."

SATURDAY, FEBRUARY 18...Royal Institution, Albemarle-street, W., 3 p.m. Mr. T. G. Jackson, "Architecture: The Byzantine and Romanesque Period." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,039. VOL. LIX.

FRIDAY, FEBRUARY 17, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

PRESIDENCY OF THE SOCIETY.

The Council have the gratification of announcing that, with the approval of His Majesty and the consent of His Royal Highness, they elected, at their meeting on Monday, the 13th inst., His Royal Highness the Duke of Connaught, K.G., as President of the Society.

The Council also passed a cordial vote of thanks to the Lord Chief Justice, who has held the office of President since it was vacated by His Majesty, and who resigned in order to make way for His Royal Highness the Duke of Connaught.

NEXT WEEK.

MONDAY, FEBRUARY 20th, 8 p.m. (Cantor Lecture.) Professor ADRIAN J. BROWN, M.Sc., "Brewing and Modern Science." (Lecture III.)

WEDNESDAY, FEBRUARY 22nd, 8 p.m. (Ordinary Meeting.) Professor J. WERTHEIMER, B.Sc., B.A., "Water-Finders."

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES ON "BREWING."

On Monday Evening, the 13th inst., Professor ADRIAN J. BROWN, M.Sc., delivered the second lecture of his course on "Brewing and Modern Science."

The lectures will be published in the *Journal* during the summer recess.

COVERS FOR JOURNALS.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s*. 6*d*. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A Meeting of the Colonial Section was held on Tuesday, January 31st, Sir WILLIAM HOOD TREACHER, K.C.M.G., presiding.

The CHAIRMAN, in opening the meeting, explained that the paper to be read was one of a series which was being given under the auspices of the Colonial Section of the Society on the "Commercial Products of the Empire." It was hoped that the series of papers would help people to realise that our world-wide Empire contained within its bounds, extending as it did through all the zones, all the raw products necessary and essential for the support and welfare of its people.

The first paper of the series dealt with the subject of Wheat, and was contributed by Mr. A. E. Humphries. The second paper was written by the Agent-General for Tasmania, and had for its subject Fruit, and the third paper was the one about to be read, dealing with the Tin Resources of the Empire, by Mr. Douglas Osborne, a member of the Legislative Council of the Malay States. The author's lot and his own were for several years cast together in the Malay Peninsula, which was one of the most successful instances of the art of British government in the way of "Protectorates." It was a country teeming with tin-ore deposits, and at one time produced more than two-thirds of the tin supplies of the world. In that country his (the Chairman's) lot was on the humdrum side of the Government public service, while the author's was on the more exciting and more lucrative side of tin mining.

The Paper read was—

THE TIN RESOURCES OF THE EMPIRE.

By F. DOUGLAS OSBORNE, M.INST.M.M.

To the average man "Tin" means but little, and, if thought of at all, is vaguely associated with pots and pans; but in reality tin is one of the most interesting of the metals, and the fact that some 100,000 tons of it are consumed annually in the arts and industries proves that

it is of considerable importance to the world at large.

Tin is a white metal with a silver-like lustre, which remains untarnished for a long time when exposed to the atmosphere. It is very soft, so soft that it can be scratched or indented by a finger nail; it is ductile and tough to such an extent that it can be beaten out to resemble paper, a form in which it is familiar to most people as a wrapper of chocolates and other sweetmeats. It is a metal which, when once used, is rarely recoverable, and, therefore, is a wasting commodity, so that unless some substitute is found, the consumption of tin must increase as the world's trade expands.

In "The Production of Tin," published by the *Mining Journal*, Professor Lewis wrote :—

"Tin occupies in many respects a unique position amongst the various metals used in the arts, due not only to its specific properties, but to an even greater extent to its mode of distribution and occurrence.

"In the first place, it is the rarest of common metals of commerce, and is produced in markedly smaller quantities. Unlike most of these metals, it is distributed sparingly throughout the world, occurring in workable amounts at but few localities; where it does occur, however, it is generally, but not invariably, found in very important quantities. Again, tin is the only common metal, except iron, the only true ore of which consists of an oxide of the metal. All the other minerals appear to have been deposited originally as sulphides, their existence in the oxidised state being due to the secondary action of atmospheric agencies upon these sulphides. Hence the other metals are found as oxides near the outcrop only of their deposits, but as sulphides in depths, while tin appears as an oxide wherever it has hitherto been found, even in the deepest mines in which it has been met with, and at depths where all other metals are known only as sulphides.

"Again, the sulphides of the other ordinary metals, when exposed to atmospheric agencies, form more or less soluble compounds; oxide of tin is notable for its great chemical indifference and for its insolubility in those reagents that dissolve most other metallic compounds. Hence the degradation of a mineral deposit containing any of the other metals is apt to be accompanied by the removal in a state of solution of those other metals.

"In the case of tin it will only lead to a concentration and purification of the oxide. This is why oxide of tin (the tinstone or black tin of the miner and cassiterite of the mineralogist) is found to so large an extent in alluvial gravels, a mode of occurrence that it shares almost exclusively amongst metallic minerals with those other chemically indifferent substances, gold and platinum."

To this property the world owes its abundant supply of the metal, for by far the greater portion of tin produced comes from alluvial deposits, and again its indifference to the action of acids is responsible for its use in the tin plate trade, by which over 25,000 tons are annually absorbed. In this trade its function is to coat steel plates so that these can be converted into receptacles for all manner of things; preserving the steel plates from oxidisation, which would quickly render them porous, it admits of much thinner steel being used and keeps the contents pure and untainted.

Other uses for tin are many. It is familiar to most people in the form of solder, and enters largely into the composition of brass, gun-metal, bell-metal and phosphor bronze.

As "white metal" it is used for type metal, pewter, machine bearings and valve packing, bottle capsules, fusible alloys, electric fuse wire, Britannia metal, tea lead, the foundation for gold and silver plating, and the manufacture of toys.

Tinfoil is pure tin.

Cheap reflectors are tinned instead of being silver plated.

In dyeing and calico printing it is used as stannous chloride, for the precipitation of colours.

Bronze powder used for decorative purposes, and having a golden lustre, is the bisulphide of tin.

Pure block tin is largely used by Chinese for the manufacture of ornamental vessels, the soft nature of the metal rendering it particularly adaptable to the characteristic scroll work of the Chinese.

That tin was known and used in the early ages there is abundant evidence.

Egyptian bronzes of the eighteenth dynasty and coins of 30 B.C. in bronze contain tin, and the commencement of the Phœnician trade with Cornwall for tin is generally assumed to have taken place about 1200 B.C. Ancient bronze weapons and tools invariably have had tin added for the sake of hardness.

The chief sources of the world's tin supply are the Malay Peninsula and the Islands of Banca and Billiton; Bolivia; Australia and Tasmania; Cornwall; South Africa; Nigeria

and Swaziland; China. It is also produced in New Zealand, Burma, the Congo Free State, Korea, Japan, Spain, Portugal, Central Europe, France and Alaska, but not in quantities that are of any importance.

THE FEDERATED MALAY STRAITS.

Of the sources named, the Malay Peninsula is the most important, as from thence comes more than half of the total supply.

Situated at the south-eastern extremity of the continent of Asia, the Peninsula consists of a narrow strip of land varying in width from less than 50 to nearly 200 miles, and extending from latitude 13° 30′ N. to 1° 18′ N. The northern part of the Peninsula is feudatory to Siam, and in this part the development of the mineral resources has hardly begun. Towards the south are the Federated Malay States, which, under British protection, have so wonderfully developed during the past thirty years. It is from these States, Perak, Selangor, Negri Sembilan and Pahang, that the major part of "Straits Tin" comes. In 1909 the amount exported was little short of 49,000 tons.

That mining for tin in these States has been going on for long years, there is evidence in the form of old workings all through the country; but it was not until the advent of the Chinese that any considerable quantity was produced, and only since their faction fights, which led to British interference and subsequent protection, that the States have rapidly developed and become the mainstay of the world's tin supply.

The tin exported from the Federated Malay States is almost entirely won from alluvial deposits. The most important of these are in Perak and Selangor, the former being at present responsible for about 56 per cent. of the total.

In the Federated Malay States during the twenty years 1890 to 1909, there has been produced 873,703 tons of tin, or an average of 43,685 tons yearly. Of this total Perak produced 447,900 tons; Selangor, 329,564 tons; Negri Sembilan, 73,315 tons; and Pahang, 22,924 tons.

The maximum production was in 1905, when the output for the States reached a total of 50,991 tons. Since then the production has diminished slightly; 48,743 tons were produced in 1909, and it appears as if there will be a greater falling off during 1910 (total 45,000). Almost the whole of this production comes from alluvial workings, as at present, with the exception of the mines of the Pahang Consolidated in Pahang, and some workings in the Kledang range of hills near Ipoh in Perak, no lode mining is carried on, and the total production from these two sources does not exceed 1,200 tons per annum. The chief centres of the alluvial workings are the Kinta Valley in Perak and the flats near Kwala Lumpor in Selangor drained by the Selangor and Klang Rivers. In these places it is hardly an exaggeration to say that tin occurs everywhere, from the surface of the ground down to depths of 250 feet, on the flat land, in the valleys, and high up on the mountains.

The Kinta Valley, which is so enormously rich in tin and which is typical of the characteristic deposits, is the valley drained by the Kinta River, the most important tributary of the Perak, with which it runs parallel in a southerly direction, the Kledang range forming the watershed between the two rivers and the boundary of the Kinta Valley on the west; on the east of the valley is the main range of the Peninsula. The valley is about thirty miles long by twelve wide and is very flat, the mountains on each side rising abruptly. Mining villages, well laid out and tidy, are scattered throughout, connected by well-made cart roads, and the main railway runs through the centre. The chief geological features of the valley may be described as a floor of highly crystalline limestone or marble, usually white in colour, and lying in the centre of the granite mountains. On the east side this limestone forms a series of wonderful pinnacles or hills, rising in cases as high as 2,000 feet above the surrounding country, covered by dense jungle scrub, and honeycombed by caves and fissures. It has been weathered to a very irregular surface, forming innumerable small pinnacles and crevices, is non-fossiliferous and its geological age is unknown. The mountains on either side are composed of intrusive granite, which has doubtless been the cause of the upheaval and contortion of the limestone, the intrusion of the granite having probably occurred simultaneously on both sides of the valley, and thereby squeezed the limestone into the extraordinary shapes which it has assumed.

The tin deposits are extremely irregular and follow no well defined lead. The richest occur in the vicinity of the granite foothills, much tin being occasionally concentrated in the fissures left at the junction of the granite and limestone, as in the case of Tronoh and Lahat. The channels and crevices in the limestone valley bed invariably are rich in tin, and it is from these shallow deposits that the majority of the tin is won by the Chinese workers. The

tin wash may be sandy or heavy clay; it may occur in layers separated by barren ground, or the whole of the ground from surface to bed-rock may carry tin; and as in the valley the holes and crevices in the limestone are filled with tin-bearing ground, so it is in the hills, even up to heights of 1,200 and 1,300 feet. Isolated deposits from time to time are found in the limestone, the most notable of these being the Tambun Mine, from which in 1903 as much as 350 tons of tin ore was won during one month, and the average for the year was some 250 tons per month. There being no connection between this deposit and any other of considerable value makes it all the more difficult to evolve a reasonable theory as to the origin of the mineral, more especially as, in the case of Tambun, the tin is much less water-worn than is the case in many of the cave deposits in the hills, which are much closer to the granite ranges, from the weathering of which the alluvial tin was most probably derived.

Mr. Scrivenor, the Government geologist, is of the opinion that it is much more probable that the bulk of the alluvial tin has been derived from the masses of pegmatite, lodes, and stockwerks which take part in the formation of the low rolling country at the foot of the high ranges, than that it was derived from the high granite mountains.

In his report for 1904 he states that undoubtedly the bulk of the tin found in the Tronoh mine had its source in the hill lying to the west of the mine.

If this theory is accepted, it becomes still more difficult to account for the presence of alluvial deposits high up in the limestone caves and on the mountains. My opinion is that the bulk of the tin deposits of the Federated Malay States came from the weathering and erosion of lodes that existed in the granites and schists. Even close to the foothills the tin deposits are almost invariably much waterworn and rounded, which naturally leads to the conclusion that they have travelled a considerable distance. Then, if the tin came from high granite hills, it is a simple matter to account for its presence in the high caves and fissures of the limestone cliffs, for where the granite pushed through and distorted the limestone, huge crevices are left which would catch the detritus subsequently washed down from above, and, acting as receptacles for large bodies of water, hydraulic power would be provided, capable of forcing the alluvium through channels in the limestone and to considerable heights.

Wherever the tin came from, however, there is no doubt that the greater portion found its resting-place on the west of the main range. These on the west side are almost continuous from Taipeng to the north to Seremban to the south, and an interesting feature is that their extent and value seem to diminish towards the south. From this it might be deduced that the main source of the supply was the mountains of Perak. On the east coast the tin-fields are less numerous, more scattered; the deposits are of a more recent period, and, as the bedrock of the alluvial workings is generally granite rock, there seems but little likelihood of discoveries being made of new fields which will equal in richness those on the west coast.

It is probable, however, that lodes of considerable importance may in time be discovered and worked in the eastern States.

For the development, in the future, of the tin resources of the Federated Malay States there is no doubt that modern machinery and abundant capital are necessary. The shallower, richer and easier-won deposits having become exhausted, those remaining require, for their development, modern engineering skill and plant capable of treating large quantities economically.

The methods by which alluvial deposits are worked may be described under four heads:—

Ground sluicing, with its modern development of hydraulicking.

Open cast workings.

Underground workings.

Dredging.

Ground sluicing is only practicable where a sufficiency of water is available and an outlet for the debris exists. It is a favourite form of mining for small parties, little capital being required. The scene of this class of operations is, generally speaking, some narrow valley up in the hills. A watercourse is cut to the face that is to be worked, and along the face a narrow channel or ground sluice, with sufficient slope to enable the valueless dirt to be carried off by the water, while the tin remains behind. The ground is then, as soon as water is turned on, hoed from the face into the sluice, and kept stirred until it is considered that sufficient has been run in, when the hoeing is stopped, and the dirt in the sluice is kept stirred until the lighter material has nearly all been carried away, and but little except tinstone remains.

Hydraulicking is but a modern development of ground sluicing, water being used to do the work. Being brought to the ground in pipes and subject to considerable pressure, the water

is directed by means of swivelling directing nozzles, known as "giants" or "monitors," against the face to be worked. This is gradually undercut at the lowest possible level, until a huge mass of ground falls down. The jet is then played on this until the whole is disintegrated and carried away into the sluices, when a recommencement is made to get down a fresh fall. In this manner very large quantities of ground are removed and treated, and naturally must find a fresh resting-place. To a certain extent this necessity is provided for by the valleys below the hydraulic mines, which are mostly hills; but as time goes on, even these become filled, and then the water-power is again called upon for assistance. By its help the debris from the ends of the sluices is elevated and stacked. These hydraulic jet elevators, as they are called, are wonderfully simple and efficient. They consist of an uptake pipe set at an angle of about 20° from vertical, having at the lower end a bell-mouthed intake, below which is set a nozzle supplying the power. All sand, water, and stones coming to the end of the sluice are caught by the force of this nozzle, shot up through the uptake pipe to a height proportionate to the requirements of the case and pressure available, and thereby the difficulty of getting rid of tailings has been overcome.

The tinstone, being heavier than the dirt containing it, travels more slowly in the sluices, and tends to gravitate to the bottom, advantage being taken of this fact to save it. For this purpose various types of sluices are used. The most primitive, and, it is maintained by the managers of the leading group of hydraulic mines, the most efficient and economical, are simple sluices cut in the bedrock, which, left to themselves, are periodically cleaned up by women working with flat circular dishes. Wooden sluices with and without riffles, or stops, are also used; but these require more water and, when riffles are employed, constant attention and stirring, which tends to keep the tinstone moving and to consequent loss.

The cost of working on a well-managed hydraulic mine is very low, being less than 1*d.* per cubic yard; but as water has generally to be brought a considerable distance in pipes and ditches, the initial outlay, before working starts, is generally heavy.

By far the greatest part of tin-mining in the Federated Malay States is carried on by open cast mining. It is a method of mining introduced and developed by the Chinese—in plain English, it consists of digging a large hole in the ground and extracting from its contents all that is of value. Where the scene of operations is on a well-defined lead of tin-bearing gravel, works of an extensive nature and some measure of permanency are undertaken; otherwise luck is largely trusted in, and too often with disastrous results.

The site for opening a mine having been chosen, and the jungle felled and cleared, a strong earthen embankment is built round, so as to prevent an inrush of flood water. Sheds for the accommodation of coolies are erected, and the necessary watercourse cut, to provide water for separating the tinstone from the gravel.

All being ready, a commencement is made to remove the "overburthen" or barren ground overlying the stanniferous alluvium. This work is always done by contract, the overburthen from the first paddock being stacked round the excavation. When the "karang," or tin-bearing gravel, has been uncovered, it is lifted by wages coolies to the wash-boxes, for the separation of the tin from the gravel. These wash-boxes are of coffin shape, varying in length from 10 to 30 feet, and are set at a grade of about 1 in 12. They are about 3 feet to 3 feet 6 inches at the widest part, where the tin is saved, and gradually narrow towards the end to from 10 to 18 inches.

At the widest part a baffle board is fixed, about 8 to 12 inches deep, over which a portion of the water used falls, and at the side on which the karang is deposited, a square aperture is cut, through which a stream of water constantly flows, carrying the karang, which is stirred by a coolie with a rake, into the box, where it is immediately caught up by the washers, working with large long-handled hoes, drawn against the stream, turned over and over and tossed, until it is considered that the box will not, with safety, hold any more tin. Then the stream through the side is shut off, and the tinstone, after a little further washing, lifted and put into tubs or baskets for transport to the store.

The first paddock having been exhausted of karang, it becomes the dumping ground for the overburthen which has to be removed from the second, and so the operations continue until the ground is all worked out.

To contend with the seepage water, centrifugal pumps, operated by portable steam-engines, are now almost invariably used; but before the introduction of these, the Chinese chain pump, driven by water-power, was the

only pump used, and in many places these are still in vogue, sometimes worked by a steam-engine, sometimes by coolies, treadmill fashion, but more often by water.

By the style of open cast mining described, depths of 65 feet were worked, but deposits deeper than that were generally left alone until mechanical haulage was introduced. Now mines of a depth of 100 feet and over are by no means uncommon.

Various systems of haulage and for the excavation of the ground have been tried, such as steam shovels and grabs, blondins, belt-conveyers, endless rope-ways, and Kimberley gears, but the system that has proved the most efficient and economical is inclined tramways, with trucks which are filled on contract rates by coolies, both Chinese and Indian.

The irregularity of the run of tin-bearing ground militates against the success of fixed mechanical haulage, whereas branches from the tram lines can be run in all directions, and the, generally speaking, heavy clayey nature of the deeper deposits renders the use of steam shovels and grabs unprofitable as compared with coolie hoe work. The former sends up to the dressing-plant large masses of hard clay lumps and stones, which have to be broken up before treatment, whereas the hoe work breaks all up and reduces the mass to a condition most favourable for treatment.

The ground excavated is sent first to the puddling plant for disintegration, the plant most generally adopted being in the form of iron vats about 30 feet in diameter by from 3 to 4 feet deep. The dirt for treatment is fed into these with a constant stream of water. There are four horizontal arms radiating from a power-driven spindle situated in the centre of the vat, and to these arms are fastened by chains heavy harrows, which gradually reduce the mass, the clayey part being floated away by water, and the heavier sand, stones, and tin remaining in the bottom of the vat until a charge is completed, when it is let out for final dressing in wash-boxes. In some installations there is a constant discharge from the puddles into long sluice boxes, the bottoms of which are armed with riffles, or stops, placed across the box at intervals of 1 to 3 inches. The puddled dirt and water travelling in these boxes is kept constantly stirred by men raking between the riffles at right angles to the flow, and the tin is deposited between the riffles. Experience, however, shows that this system is wasteful of tin as compared with concentration in the puddling vat. Horizontal puddlers, consisting of a box some 10 feet in length, with a central shaft armed with knives revolving at a high speed, are also used.

Underground working is confined to those deposits where the amount of overburthen is too great to admit of the proposition being worked open cast. It is often adopted by small parties working on tribute, in order to avoid the capital outlay necessary to open a mine.

The method of working is to sink a number of shafts at regular intervals, the extent of which depends on the nature of the ground to be dealt with. Through the shafts the "karang," or pay dirt, is brought to the surface for treatment, and the whole is thus gradually blocked out as the various shafts are connected below.

By this method depths of 250 feet have been reached, and where the tin bed is deep, of little thickness and width, this is the only way by which it could be mined; but generally it is not economical, for though the cost of removing overburthen is avoided, the expense of timbering the shafts and drives adds so much to the outlay on excavation that, in most cases, the price at which the karang is raised exceeds considerably what would have been necessary if the proposition had been dealt with by open cast. As a consequence, much ground which is rich in tin is left untouched, owing to there not being quite sufficient tin to pay for its excavation and the necessary timbering, in addition to which there are usually layers of karang above the main layer which are left untouched, and which in an open cast mine would have been taken advantage of to reduce the cost of stripping.

There are many instances to prove that the values left in underground mining are considerable, mines after having been worked as far as they could profitably be dealt with by this method having been open cast and paid handsomely. One instance is the Tambun Mine, before referred to, which was worked to the limit admissible by shafting, and is now a highly profitable concern, worked as an open cast mine. In fact, as regards Chinese-run underground workings, it may be taken that only the richest portions are touched, and the system must, as already stated, be regarded as wasteful, and, therefore, should not be encouraged.

Dredging is of two forms—bucket dredging and dredging by means of centrifugal gravel pumps. No bucket dredging has so far been attempted in the Federated Malay States,

though the use of bucket dredges for the recovery of gold and tin from river beds and flats is general in Australia and New Zealand. A bucket dredge is nothing more nor less than the ordinary dredger, slightly modified, which most people have seen clearing away accumulations of mud and sand from harbours. In mining use, instead of being shot into a hopper at the side, the dirt raised by the buckets is dumped into a revolving trommel, from the centre of which strong jets of water are playing, which disintegrate the lumps, allowing the smaller particles to pass through the perforations in the trommel plates on to tables or other value-saving appliances, the valueless debris passing out over the end of the pontoon, and, where necessary, being elevated and stacked by another system of buckets. The great advantage of dredging lies in the large quantities of ground that can be treated at a very low cost.

Dredging by centrifugal pumps is a modern adaptation of the principle of hydraulic mining, and was first introduced in Australia. Essentially it is hydraulicking at a low level, the difficulty of getting rid of the tailings being met by the introduction of a centrifugal pump, which raises them to a height at which they will find an outlet by gravitation.

The plant is carried on a strong pontoon, and consists of the power in the shape of engines and boilers, or electric motors, the gravel pump, electric lighting plant, and, where natural gravitation does not supply sufficient pressure, the nozzle pump to force water through monitors to break down and disintegrate the ground.

The ground is undercut in the manner already described when dealing with hydraulic mining, and gravitates through a channel cut in the bedrock to the sump of the gravel pump, whence it is sucked up and delivered into a sluice box, in which the tin remains, while the sand and gravel is carried off by the water. Of course, in order to gravitate the dirt and water to the sump, the channels cut in the bedrock must rise higher and higher as the faces become more distant from the sump. When such a distance has been reached that it is no longer possible to gravitate the whole of the tin ground to the pump, the entire plant has to be brought closer to the face. This is done—after a bed for a pontoon has been prepared—by allowing water to flood the paddock and float the pontoon. The pontoon is then towed to the new site, and water is pumped out, the pontoon bedded down, and operations recommenced.

Ground to a depth of 150 feet has been worked in this way by a series of two lifts, and by a single lift a depth of 100 feet has been reached. Working costs are low, though the wear and tear on pumps is heavy, and renewals of wearing parts have frequently to be made.

For the future development of the tin resources of the Federated Malay States, plants of this description must be the mainstay if cheap power can be procured. Already it has been demonstrated practically that ground which has already been worked Chinese fashion, and abandoned as exhausted, can be worked profitably, and it needs only the introduction of some more economical means of generating power than is at present available, for the thousands of acres of so-called exhausted tin-fields to be profitably reworked. The substitution of suction gas for steam has already met with a considerable measure of success in the Sungei Raya Mine in Kinta, where the plant has been intelligently treated, and there is a scheme in prospect for generating electric energy by the water-power of the Kinta River. Should this scheme be carried to a successful issue, working costs, where its electric energy is employed, must be reduced to such a low figure that but little land in the Kinta Valley and other mining fields is too poor in tin not to be a payable proposition.

Given the means of systematically turning over the land that has already been worked, there is no doubt that many rich deposits, the existence of which is at present unthought of, will be discovered, and in this way the output of the Federated Malay States may be maintained at a high level for many years to come.

So far the alluvial resources only have been dealt with; but, in addition to these, there are the lodes to be developed, and in a country where such abnormally rich alluvium has been found, all of which at some period must have come from the decomposition or erosion of metalliferous veins in the rocks, it is but reasonable to presume that time and patience, with the assistance of capital, may discover the sources of the alluvial supplies and develop them into profitable tin-producing mines.

Already enterprise has begun to develop the lodes in Perak and Pahang. So far, in Pahang, the majority of the tin won has been found in the slate country, overlying the granite, none of the lodes having been followed through the slates into the granite.

The property of the Pahang Consolidated Company at Sungei Lembing (formerly owned

by the Pahang Corporation and the Pahang Kabang Co.), has been worked for over twenty years, and it is said that more than thirty lodes have been discovered, having an east to west course, the angle of dip varying from ten degrees to forty degrees, according to Mr. W. H. Derrick. The country in which the lodes have been worked is schist or slate overlying the granite. Mr. Scrivenor considers that the lodes here are fissure veins, and expresses the opinion that they will continue to great depth. Certainly the lodes can in some cases be traced into the granite, but the measure of success that has so far rewarded the liberal development policy of the Pahang Consolidated Co. is so small that an opinion as to the future value of the property cannot be formed.

Mr. Scrivenor and Mr. Sydney Fawns both consider the outlook promising. The latter, in his book, "Tin Deposits of the World," writes:—

"The lode at Bundi constitutes one of the best defined and richest lodes at present operating in the Malay Peninsula. Taking this lode in conjunction with the lodes at Sungei Lembing and other places in the Kuantan district, forty miles to the south, and the district of Sungei Ayam, twenty miles to the north, goes to prove that a large lode-mining centre exists in this part of the peninsula."

But at the Bundi Mine, again, the lode hitherto worked has been in the schists or at the contact of the schists and granite, the lode proper being entirely composed of chloritic schists.

The late Mr. Warnford Lock, however, in commenting on the Sungei Lembing lodes in his book, "Mining in Malaya for Gold and Tin," writes:—

"They never possess two distinct walls, and very rarely one. They appear rather as brecciated or 'mullocky' lodes, or as impregnations of the shattered country, and are most irregular in size, in proportion of lode matter to the total width, and in richness of contents in tin. Whether any *workable* lode will ever be traced into the granite is still quite uncertain. It has not been done yet; and in the only cases so far encountered where the lode can be seen at all in the subjacent granite mass, it is very small, in exceedingly tight ground, and barely stanniferous."

Mr. Lock's opinion of the Bundi Mine was not any better—in fact, he questions the existence of a lode at all.

Lodes rich in wolframite and tin have been worked in the Gopeng district of Kinta in the decomposed schists, but these invariably ceased at the contact of the schists with the granite, though in the schist country they were strong, varying in width from 18 inches to 3 feet and with well-defined walls.

In the Kledang range of hills, close to the village of Menglembu, in Kinta, a series of lodes have been discovered in the granite, and are at present being developed. The country rock is a hard granite. The general strike of the rock is N. 58° East, in which direction fissures occur, varying in width and at irregular intervals. These fissures are filled with mineral, cassiterite, arsenical and iron pyrites, and galena, cassiterite predominating, veins of it, almost pure, being in some cases as much as 5 inches thick. The stone intervening between the main fissures has also been enriched by the mineral permeating innumerable small veins which run in irregular courses from the main mineral bodies.

Unfortunately, the capital at the disposal of those interested in these lodes is quite inadequate, and development work cannot be pushed ahead.

The Menglembu property has two shafts extending in depth to 300 feet in granite, both of which have been sunk on the main lode. Levels driven at right angles to the strike of the rock have discovered parallel lodes of varying width. The main lode has been traced underground for a distance of 600 feet, and seems to have improved in value as greater depth was reached.

Assays taken at various parts of the workings gave irregular values, and the manager states that the stanniferous ore bodies occur in lenticular shape following a quartz vein which runs through the granite.

Chinese and other workings in these hills have disclosed the presence of many outcrops of lodes, all running parallel to those being worked at Menglembu, and there appears to be no doubt that there is here a mineral zone only waiting for sufficient capital to develop into a valuable source for tin.

In addition to the true lodes, of which there are indications, there are also the stanniferous pegmatites, which may form an important reserve to the tin resources of these States.

All through the States this rock occurs, and the Government geologist writes of it as "pegmatite *in situ* bearing tin ore disseminated through the mass, and also in small pockets and leaders," and that "it is possible that the pegmatite goes down for enormous depths."

At Gopeng and in the Kledang Hills, in Bujang, Malacca, and many other places in Perak, the pegmatites, where they have been softened by the kaolinisation of the felspar, have been worked for tin. In Pahang in various places, and in Negri Sembilan there are also instances of this class of workings. In the latter State large quantities of tin have been won by hydraulicing the soft pegmatite. The development of this source of supply must be slow, owing to the remote situation of the localities in which the deposits occur and the generally low average value of the mass. The occurrence also of hard portions, which will not yield to the influence of water, has hitherto retarded the systematic treatment of any of the known bodies of this class of rock, while the more easily won alluvial deposits still continue to provide remunerative employment for the mining labourer.

For the immediate future the tin supply from the Federated Malay States must continue to depend upon the alluvial resources; but as these become less abundant, and as the mining of them gradually passes from the hands of individuals into those of companies, then more attention will be given to the development of the lode resources, and important and valuable discoveries are certain to follow.

Australasia.

Next in importance to the Federated Malay States as a source of our tin supply is Australia, with which I include Tasmania. The output for the twenty years ending 1909 was 161,560 tons, the average yearly production from each colony being :—

	Tons.		Tons.
Tasmania . . .	3178	. Highest in 1908 .	4520
Queensland . .	2733	. „ „ 1907 .	5140
New South Wales	1685	. „ „ 1890 .	3668
West Australia .	482	. „ „ 1907 .	1424

Tasmania's production in 1909 was 4,511 tons, the chief mines being Mount Bischoff, Mount Bischoff Extended, Pioneer and Gladstone District Alluvial Mines, the Briseis group, Moorina District, Weldborough Mines, Blue Tier, St. Helens and Avoca.

Of these Mount Bischoff has been working since 1872.

This mine is situated in the north-west, some 45 miles from the coast, on the top of a mountain 3,500 feet above sea-level and 1,200 feet above the surrounding plain.

W. von Fircks, in a paper describing the deposit, writes :—"The tin deposits appear in an area of quartzites and clay slates with dykes of quartz porphyry. Granite is present, but at some distance from the mine. These deposits are in part fissure veins carrying cassiterite . . . Another part of this deposit is formed chiefly by the replacement of porphyry dykes."

The ore is generally of low grade, the average for the whole mine being about 1¼ per cent. cassiterite. It is mined chiefly by open quarries, the ore being broken and dressed by means of stamp battery, tables, buddles, etc.

On the north side of the hill some good alluvial was found and worked, and from the whole mine, since work was commenced up to the end of 1909, over 68,000 tons of ore have been won, and at present the average monthly output is about 85 tons of ore.

Mount Bischoff Extended is also a lode deposit producing about 10 tons of tin monthly.

Pioneer Group of Alluvial Mines in the north-east are working alluvial drifts in the Ringarooma Valley by means of suction dredges down to depths of 120 feet, the output amounting to about 90 to 100 tons of ore monthly.

The Briseis Mine and Brothers' Home are hydraulic propositions in the Derby district, working a gravel deposit covered by barren overburthen consisting of basaltic soil in which occur hard basaltic boulders. Water was introduced under pressure from a distance of 30 miles, so that the whole can be treated by hydraulicking, excepting the rocks and boulders, which have to be trucked. During 1909 little short of 1,000 tons of tin ore was saved.

Of the other alluvial mines there are none deserving of special mention.

The Anchor Tin Mine in the north-east works a mass of comparatively soft tin-bearing granite, the whole of the stone broken being taken to the mill and crushed; and mining about 1 per cent. tin ore can be made to pay, as the costs are kept very low.

A new tin-field has recently been discovered on the Stanley River, south of Mount Bischoff. Here prospecting has proved alluvial deposits averaging for a depth of 39 feet 4 lbs. of tin ore per yard, and there are lodes said to be worth 7 per cent. of cassiterite.

Latest reports point to increased activity in the tin-mining industry in Tasmania, and the introduction of hydro-electric power should stimulate the production by reducing working costs.

When dealing with tin the Report of the Government Department of Mines, Queensland, for the year 1909, states :—

"The steady and satisfactory price of tin

throughout the greater part of the year has been reflected in the activity in this branch of the industry, more especially in Herberton and Chillagoe Fields, where new lodes have been discovered, old workings have been reopened, and richer and more extensive ore bodies have been disclosed in some of the established and productive mines."

The Vulcan Mine in this district has, by fresh discoveries, developed promising ground for the future in the lower levels on the lodes, but at Stannary Hills the promise, based on borings by diamond drills, of further valuable ore bodies, has not been realised. Koorboora, in the Chillagoe division, has improved its position by the discovery of a valuable lode worth 20 per cent. of tin oxide, but generally in this district the ore deposits seem to be of an uncertain nature, and the alluvial workings have ceased to be productive.

In the Kangaroo Hills Field the easily won alluvial tin has almost been exhausted, and lode workings have not been sufficiently successful to induce any fresh developments.

In the Cooktown district the alluvial mines with an increased water-supply are now doing better, but of lode tin in this district but little has been won, and, notwithstanding the increased value of tin, there does not appear to be any prospect of any increase in the output of this colony.

In New South Wales there was a small increase to record in the production during 1909, due to increased activity in dredging operations, which produced 69·5 per cent. of the total yield of tin, chiefly from Tingha and Vegetable Creek, but with good assistance from Wilson's Downfall and Glen Innes Division. During the year it is recorded that mining for lode tin came in for little attention.

In Western Australia the output has also considerably decreased, being 225 tons less than during 1908. Practically the whole was produced from two fields, the Pilbarra and Greenbushes, and, in the Report of the State Mining Engineer, no hope is held out of there being any prospect of an improvement, though the lodes at Greenbushes may prove valuable if sufficient capital for their development can be obtained.

South Africa.

The Bushveldt Tin Mines in the Transvaal were at one time expected to prove large producers. They were favourably reported upon by an expert, and a strong company was formed, but the result of their operations has not been satisfactory, and the mines are said to be still in a state of development.

The Kuils River alluvial deposits near Cape Town have not produced any significant quantity of tin, but the Zweiplaats Mine, working pipes in granite, is now doing well, the ore treated averaging 20 per cent. tin oxide.

It is, however, from Swaziland that most of the South African tin comes. Here, in 1889, Mr. Ryan discovered alluvial tin in payable quantities, and alluvial deposits of considerable value and importance are known to exist in the valleys of the Embabane and Usutu rivers.

Swaziland Tin, Limited, has been operating during three years with very gratifying results for its shareholders.

At first, operations were confined to ground sluicing, manual labour serving to shift the ground. Recently, however, a hydraulic installation has been completed which in last year, during the months of July, August and September, produced 91·5 tons of tin. This result, obtained during the driest months of the year, can, the manager confidently states, be largely augmented when more water is available. The company has in hand the introduction of further water-supply, and prospects for the future are considered very bright.

Sketchy prospecting in many of the beds of the tributaries of the Embabane proves that there is tin in all the valleys, and as prospecting in a more systematic manner and on a large scale is about to be undertaken, important developments may be looked for.

Nigeria.

Much attention has of late been attracted to Northern Nigeria and the tin deposits there discovered.

That tin was found in Nigeria has been known for many years, owing to "faggots" of pure tin having from time to time found their way down to the coast; but it was not until 1902 that any serious endeavour was made to trace the source of the supply.

In that year the Niger Company despatched an expedition, under Mr. Laws, to examine the country, and tin was discovered in the province of Bauchi.

Within the past few years many companies have been formed to develop the tin-fields. All of these companies are represented on the ground by their managers and assistants, but even now there is very little reliable information available as to the value or extent of the alluvial deposits.

Reports published with prospectuses bristle

with glowing accounts of wonderful rich finds, but on analysis there seems to have been very little prospecting on systematic lines.

Attention has been mostly, if not entirely, given to shallow deposits in the river beds near the sources of the streams, and though undoubtedly rich pay dirt has been found in places, as is evidenced by the tin ore exported by the Naraguta and a few other mines, the nature of these deposits points to the conclusion that they are concentrates behind natural bars—that they will eventually prove to be patchy and of short life.

Mr. A. F. Calvert, in his "Tin Fields of Nigeria," gives much interesting historical information and a very full account of the various Nigerian companies, with details of reports by their experts; but, apart from the historical matter it contains, the book is of little value as a work of reference, most of the information being of an *ex parte* nature.

The *Mining Journal* of the 19th November last contains an article, "from a correspondent," on Northern Nigeria. The article commences by stating that, after several months in the country, the writer still has difficulty in obtaining any reliable data. "With regard to the 'power' companies here, I think that this phase of mining, if on a large scale, may be dismissed altogether. . . . The situation, in a few words, is too much water in the rainy season, and too little or none in the dry season. In some localities the river water dries up altogether.

"But I put these facts forward as a counterbalance to the undoubted richness of much of the ground taken up.

"*Values.*—Information is not available as yet, everyone being absorbed in taking up areas . . . I have seen ground in Ninghi going at least 5 lbs. of very coarse cassiterite per cubic yard; the average all over will remain at this figure, or drop to 4 lbs. throughout . . . This instance is, however, exceptional, I should say, taking into consideration the coarse nature of the ore.

"Very few properties are being taken up on the square area, owing to tin not existing in many cases outside of the actual river bed or far into the banks. . . . These areas of six miles by half a mile will, when producing, probably average all round from 4 to 5 tons ore per month, but it will take some getting."

Of labour there is a good supply available at low rates of wages, but until the railway is completed to the coast, the cost of transport to and from the mines (estimated at £25 to £30 per ton of ore) must hamper the development of the fields, which, for this reason, will be slow; and, therefore, a few years must pass before Northern Nigeria will be able to demonstrate the position it can take among the tin resources of the Empire.

Cornwall.

Cornwall at one time produced 14,000 tons of tin annually, but the average for the ten years ending 1910 has fallen to 4,800 tons.

With the exception of the famous Dolcoath Mine, very few of the many mines in Cornwall are worked at a profit, and, passing through the county, one sees abandoned mine workings on all sides. Many mines still continue to operate year after year, but without any benefit to the shareholders, and it would appear that the mines are run more for the sake of the employment they provide than for anything else. Their condition does not seem to improve with an advancing price of tin—a fact probably due to advantage being taken of the higher price to work poorer ground and to develop more reserves as a stand-by when the inevitable fall occurs.

A few years ago much was said and written of the improvements that could be effected in Cornish mines if the prejudice for antiquated Cornish methods of mining and ore-dressing could be eliminated. Several companies with ample capital were floated to demonstrate the truth of this theory. Much work was done, much money was expended, but the superiority of the newer methods still remains to be proved—at least, in so far as shareholders are concerned.

The main factor which militates against the success of Cornish mines is the depth at which mining is carried on, and the quantity of water that has to be pumped. As an instance of this, the Basset Mines have to pump from a depth of 1,800 feet 90 tons of water for every ton of ore raised. Pumping charges alone on this mine amount to 5*s.* 4*d.* per ton of ore, which on 42,500 tons of ore (the amount mined in 1909) means a sum of £11,328.

There does not appear to be any prospect of improvement in the mining industry in Cornwall. Probably the output will continue to be maintained at or about the present level of 5,500 tons, but any material increase is unlikely.

Attention has recently been given to the alluvial deposits on the Goss Moor, where a centrifugal dredging plant has been erected. So far the ore won has not covered working costs, but better results may be obtained when

those responsible for the running of the plant become acquainted with its idiosyncrasies.

Farther east a bucket dredge is in course of erection, and its operations will be watched with interest, but under no conditions are the alluvial deposits of Cornwall likely to make much difference in the world's tin supply.

TIN SUPPLY IN TONS OF 2,240 LBS.

YEAR.	Shipments from				Banca Sales in Holland.	Billiton Sales in Java.	Production in Cornwall.	TOTAL.
	Straits.	Australia.	Bolivia.	S. Africa.				
1909	58,500	5,350	18,000	3,000	11,600	2,200	5,600	104,250
1908	60,500	5,850	17,000	1,700	11,500	2,200	5,400	104,150
1907	52,500	6,350	15,300		10,890	2,150	4,900	92,290 (*a*)
1906	57,200	5,900	16,380		8,980	1,900	4,900	96,760 (*b*)
1905	57,000	4,900	11,900		9,625	2,625	4,500	90,550

(*a*) Includes 200 tons from China. (*b*) Includes 1,500 tons from China.

From the above table it will be seen that in 1909, out of the total world's supply of 104,250 tons of tin, 72,450 tons came from within the Empire, though some of the tin shipped as "Straits" was mined in the independent States of the Malay Peninsula and in Billiton and Singkep.

For years to come there should be no difficulty in maintaining this rate of production. In fact, there appears to be more probability of an increase than of any falling of.

The high value at present of tin is certain to stimulate production throughout the Empire, with the exception of the Federated Malay States, where, as statistics prove, the production decreases as the value of the metal increases. Any falling off here, however, should be made good as the development of Northern Nigeria and Swaziland goes on, so that there is no reason to fear that the world's requirements for tin will not be amply provided for in the future, as has been the case in the past.

DISCUSSION.

MR. HERBERT W. ELY (Secretary, Tasmanian Government Office), in opening the discussion, after apologising for the absence of Dr. McCall, the Agent-General for Tasmania, thought the author was to be congratulated on a paper which was not merely interesting to professional mining men, but also to the mere layman. Tasmania was the principal tin-producing State of Australasia, and it prided itself on the fact that it now possessed the largest tin mine in the world, which was also one of the best-paying mines. It was only some thirty-five years ago that the statement was made that the Mount Bischoff Mine was petering out, and would have to close down; but it had gone on ever since, and had been a regular dividend-payer for over thirty years. He confessed to a feeling of disappointment that the author had not mentioned, in connection with the mining districts of Tasmania, the large tin-field of north-east Dundas. It had not been very much worked up to the present, but the district was a very large one, and was highly tin-bearing, both alluvial and lode. Farther to the west there was the Stanley River field, which had proved to be extremely rich in tin, and there was every indication to show that when those districts were opened out, Tasmania would, within the next few years, double or perhaps treble its output of tin. The author had stated that there were no bucket dredgers in the Malay States. This was true, but, as a matter of fact, there was a Tasmanian company operating at Tonkah harbour, about 200 miles north of Penang, and successfully dredging the harbour for tin by means of bucket dredgers. It would be of interest if the author could state whether the success of tin-mining in the Straits Settlements was due to the high percentage of tin obtained, or the cheapness of the cost of production, including labour. It was quite conceivable that in places where labour cost only a few shillings a week, tin deposits could be worked profitably, whereas the reverse would be the case if the Australian rate of wages of 8*s*., 10*s*. or 12*s*. per day had to be paid.

MR. T. L. LEWIS stated that he had travelled all over the world searching for tin and gold. In Bolivia he had ridden for four days over country in which he had picked up pieces of alluvial ore, as large as his head, almost every five minutes. He brought some of those pieces home to England, and on their being assayed by an eminent tin expert they gave 27 per cent. of tin. He believed that in the future no country would be equal to Bolivia in the production of tin. He had made a careful study of the tin-bearing districts of Cornwall, and believed that that county possessed a very large area of some of the finest alluvial tin country in the world. He further believed it would be found

that Cornwall in the future would produce tin in very large quantities, which, if not exactly up to the scale of its old production, would very nearly equal it. There were tin values in Cornwall which were very much higher than the general average values he found in Australia, while the quality of the tin in Cornwall was about the best in the world. He firmly believed that in the future there would be a big alluvial tin industry in the county. Miners did not yet know all that was to be learned with regard to the saving of tin, no system having yet been adopted by which the finer tin might be saved, and the general output of the metal thus increased. The author had stated that tin alluvials contained platinum and gold, but he had not mentioned wolfram. He had seen alluvial deposits in Cornwall containing wolfram, which would pay handsomely if worked on modern lines.

Mr. J. H. COLLINS said the author had made the statement that the mines of Cornwall were mainly worked for the benefit of those who worked them. As a mining man, he would like to know whether the same remark did not apply to the mines all over the world. If the author tried to maintain that in that respect Cornishmen were different from other people, he thought he would fail absolutely. There was a very simple reason for the decline in the production of tin in Cornwall in the last few years. Not many years ago tin was being raised in twenty different districts in Cornwall, while it was now being raised in any quantity in only three districts. There were fashions in mining as in everything else, and some of the mines had gone out of fashion. They would come into fashion again in the future, but the great district which had yielded the largest amount of tin in Cornwall for many years past had maintained its output. Although Mount Bischoff had a great reputation and record, he thought no other tin mine in the world had a record like Dolcoath, which had been working continuously for a great deal more than a century, giving fair profits for a very great part of the time. By-and-by, when Cornwall came into fashion again, and the derelict districts were reopened, the production of tin in Cornwall would increase to something like what it was previously, and the dismal predictions which had been put forward in regard to the industry in that county would be found to have no ground for justification whatever.

Mr. WILLIAM S. LOCKHART mentioned that for the sake of completeness he thought the paper should state that tin existed in the western part of Devon, as well as in Cornwall. Although Devon was not at present a large producer, he believed that alluvial tin from Devon occasionally came into the market. In wandering round Dartmoor, visitors would see that recent tin-streaming work had been done, and ample evidence, not only of the "old man," but also of the "ancient old man," as the tin-streamer of antiquity was locally termed. He desired to emphasise the previous speaker's remarks with regard to the tin alluvials of Cornwall. Alluvial tin was worth more than mined tin, and now that wolfram was commercially utilised, and could also be efficiently separated from the tin, there was far more inducement to work the alluvial tracts of the county. With better methods of mining, and a more thorough grasp of local conditions, he believed alluvial tin-mining in Cornwall would become a profitable industry. He desired to ask the author whether much wolfram was found in the tin deposits of the Malay Peninsula. He had been much interested in the author's remarks as to the white limestone, as he had met with an apparently similar formation of massive white calcspar in the ruby mines of Burma. Occasionally there were vast caves in this rock containing rich alluvial deposits, from which the finest rubies were obtained. It would interest him to know if such caves existed in the formation referred to by the author, and also whether tin occurred actually in the rock itself.

Mr. C. G. MOOR thought the principal reason Cornish mines had not paid was that the miners commenced mining from the top, instead of from the bottom. That process had had the effect of letting the surface-water down into the mines, and it would eventually drown them out. More modern methods of sinking a deep shaft avoided that drawback, and it was a point worth considering in opening up a new mine. The author had referred to the Anchor Tin Mine, in Tasmania, and had stated that mining about one per cent. tin ore could be made to pay. As a matter of fact, the actual recovery in that mine was no greater than 3½lbs. of black tin per ton of rock crushed, and that ore had to be blasted out of the face of a mountain. It was the most remarkable tin mine in the world for the low cost of working, and, so far as one could tell, it might be inexhaustible. It was simply a huge mountain of granite, 700 tons of which were being crushed per day. He hoped something would be said, in the course of the discussion, about the tin-fields in the Tanganyika district, some statements he had heard with regard to the discovery of tin there being to the effect that those tin mines would eclipse every other mine in the world. He wished the miners every success in working the alluvial tin ores of Cornwall, but the great difficulty experienced there was that only a few landowners would give permission to sluice off the surface of the property. In Tasmania no one said anything if the miner washed away the whole side of the hill; but it was seldom allowed in this country. It also had to be borne in mind that most of the alluvial tin that had been profitably won in Cornwall was obtained when wages were something under one shilling a day, and not four shillings, as they were at the present time. He thought there must be gentlemen present at the meeting who had first-hand knowledge of every tin-field in the world, and he suggested that most valuable information would be obtained if those gentlemen were to add to the information about the particular district with

which the author had dealt, contributions in regard to all the other tin-fields of the world.

Mr. JOHN VIVIAN asked what was the amount of royalty paid by the Malaya Tin Mining companies to the State. In Cornwall it was usual for the miner to have a twenty-one years' lease, a royalty being paid of anything from one-twentieth to one-thirtieth of the whole of the produce. That was one of the reasons for the decreasing output in the Cornwall mines. In the mine with which Mr. Collins was connected, a profit of over £17,000 had been made, and out of that amount over £3,000 had been paid in royalties. He agreed with the previous speaker that the day was coming when not only the alluvial deposits of Cornwall, but also many of the mines which had ceased to be worked during the time of the very low price of tin would be worked again. Given sufficient capital, men who thoroughly understood the work, and fair terms for the working of the mines, Cornwall would again be one of the largest tin producers of the world.

Mr. SYDNEY FAWNS, in referring to the quotations from various books given in the paper, said that Mr. Lock in his book used the word "lode" mostly in a commercial sense, whereas Mr. Scrivenor and he used it from the scientific standpoint. The remarks made with regard to the Sungei Ayam did not agree with Mr. Lock's opinion. There was no doubt there about the lode entering the country rock, but it was not payable, and this opinion was endorsed by Mr. Scrivenor. Personally, he looked upon Mr. Scrivenor as the best geologist Malaya had ever possessed. Another point in which he differed from the author was that all the tin came from the lodes, but why should not the stockwerks and dykes be responsible for it to a very great extent? If the author had made a short statement in regard to the extraordinary deposits the French were working in the limestone, it would have been most interesting. The only similar instance of which he was aware was the tin obtained from the limestone in Greenland; but in that case the undertaking did not pay, owing to the rigorous climate. He further wished to say that Mr. Laws was not the discoverer of tin in Bauchi. The first man who went to the tin-fields of Northern Nigeria was Richard Provis, and the next man—who was the real discoverer—was Mr. G. R. Nicholas. Laws replaced Nicholas after the latter came back; but, on the other hand, he thought Mr. Laws deserved great credit for staying for three years by himself in a country inhabited by cannibals. That, in his opinion, was one of the finest pieces of work any engineer had ever done. The paper was a most valuable one, but he wished to throw out the suggestion that the author would do an excellent piece of work if he would write a paper for the Institute of Mining and Metallurgy, giving details of the costs of working, costs of pumping, and a few drawings. Such information from a practical man like the author would be most valuable, if he could provide it without giving away official secrets.

Sir WILLIAM TAYLOR, K.C.M.G. (late Resident-General, Federated Malay States), spoke of the increasing opening that existed for the employment of European capital, enterprise, and supervision in the more effective and scientific exploration of the tin-fields of the Malay Peninsula. Owing to the interest that people took in rubber at the present time, something was getting to be known about that part of the Empire, so far as the cultivation of rubber was concerned, but comparatively few people appeared to know anything about the great mineral wealth of the country. Few people knew about its tin-fields, and still fewer about how much tin had done for its development and expansion. It was largely due to the revenue derived from the royalties collected on the export of tin that the administrators of the country had been able to do so much in the way of development—in the making of roads thousands of miles in length, the building of railways, the creation of harbours and towns, and the construction of public works generally. The revenue had increased in the thirty-five years that the Malay States had been under British protection and under the control of British officers, from less than £80,000 in 1875 to close on three millions in 1909. There had also been a marvellous expansion of trade, unparalleled in a country of its size and population. In 1909 the value of the exports amounted to nearly nine millions sterling, and the imports to nearly five and a half millions sterling, more than two-thirds of the former being accounted for by tin. The natives of the country had not taken an active part in the development; the Chinese, the natives of Southern India, and the British had been responsible for it. Nevertheless, the people of the country were prosperous, contented, increasing in numbers, and were well looked after by a stable and paternal Government, which provided them with education and other so-called blessings of civilisation, of which they were not slow to take advantage.

Mr. F. DOUGLAS OSBORNE, in reply, said that Mr. Ely had asked if he considered there was any special reason why so much tin was won in the Federated Malay States, and if that reason was not more than probably due to the fact of lower rates of wages being payable there than in the Australian colonies and most other places where tin was won. He did not think it was, for the reason that where Mr. Ely was able to employ one intelligent European it was generally necessary to employ four or five Asiatics and negroes, in addition to providing European supervision to see that they did not sleep too much. He was afraid Mr. Collins did not quite appreciate what he said with regard to the mines in Cornwall. He said it appeared that the mines were run more for the sake of the employment they provided than for anything else. That certainly was not the case all the world over. People generally put money into a venture for the sake of what they could get out of it, and not for the philanthropic reason of providing labour for

a certain number of men. With regard to the remarks of Mr. Lockhart, most people knew that a certain amount of tin came from Devonshire, but the quantity was so very small that it was hardly worth mentioning. Wolfram was certainly found in the Malayan tin deposits. He should have mentioned that himself if he had been describing tin; but the statement made in the paper that tin, platinum and gold were found in the alluvial deposits was a quotation from a book by Professor Lewis, published by the *Mining Journal*. "Amang" might be taken as being a generic term for anything that was not easily separated from tin. It occurred in various forms, but principally in the form of titaniferous iron. He had also been asked whether tin occurred in the limestone caves and deposits. He made mention of that fact in his paper, and endeavoured to account for its presence there. Tin was also found in crystals in the limestone. Mr. Sydney Fawns had drawn attention to his neglect to deal with the very interesting deposit which was worked in Kinta. His reason for doing so was that the deposit had almost entirely ceased to exist; it had been completely mined out, and to deal with the subject at all called for a paper in itself. Mr. Vivian asked what were the royalties paid in the Federated Malay States, and in what way they compared with the very heavy dues paid in Cornwall. In the Federated Malay States, the mining land was held by the miners under a lease from the Government for twenty-one years. The royalty paid to the Government was not one based on profits, but on the gross value of all the tin won, and it amounted at present, roughly speaking, to 12 per cent. of the total value. It was on a sliding scale. He was glad to accept Mr. Sydney Fawns's corrections, because his own knowledge of Nigeria was nil. He worked hard to gather some information with regard to Nigeria for the purpose of the paper, and there were only two sources from which he could get it—the *Mining Journal* and Mr. Calvert's book. Unfortunately he took one extract from that book, and it happened to be wrong.

On the motion of the CHAIRMAN, seconded by Mr. BYRON BRENAN, C.M.G., a vote of thanks was accorded to Mr. Osborne for his valuable paper, and the meeting terminated.

TENTH ORDINARY MEETING.

Wednesday, February 15th, 1911; JOHN MURRAY, J.P., D.L., F.S.A., in the chair.

The following candidates were proposed for election as members of the Society:—

Bell, Thomas, Messrs. John Brown & Co., Ltd., Clydebank, Scotland.
Byrne, James, 24, Broad-st., New York City, U.S.A.
Cookson, Clive, Oakwood, Wylam, Northumberland.
Dubilier, William, 431, Lumber Exchange Building, Seattle, Washington, U.S.A.
Lee, Harold, 56, Oxford-street; and Fairfield, Broughton Park, Manchester.
Lello, Thomas Stanley, High-road, Chadwell Heath, Essex.
Mackay, Robert John, Secretary's Office, General Post Office, E.C.
Mansell, Walter H., 405, Oxford-street, W.
Pitt, T. E. Sandford, Calne, Wilts.
Srivastava, Jwala Prasad, B.Sc., Municipal School of Technology, Manchester.
Sunderland, John Samuel, 37, Aberdeen-road, Highbury Park, N.
Todd, John, Hamilton House, 155, Bishopsgate, E.C.

The following candidates were balloted for and duly elected members of the Society:—

Bell, A. Mitchell, 56, Stanley-road, Halifax, Yorks.
Hill, W. Hereward, Canton, China; and Fairmount, Sidcup, Kent.
Hope, William Henri, The Studio, South Croydon.
Miles, T. R., 9, Brighton-terrace, Brixton, S.W.
Oosman Sahib, Khan Bahadur S.M.V., B.A., B.L., Presidency Magistrate, Madras, India.
Pillai, Perumana Narayana, Kayangulam, Travancore, India.
Sykes, John Guttridge, 88, Marlcliffe-road, Hillsborough, Sheffield.
Young, Rev. William Edward, Brook Lawn, Queen's-road, Teddington.

The CHAIRMAN, in introducing the reader of the paper, said the statement was often made that people who lived at the present time would frequently be placed in a difficulty if they had to describe to their forefathers the familiar articles in everyday use. For instance, how many of the audience would be able to describe the telephone or the locomotive to Dr. Johnson? It was a discredit to the nation that such should be the case; and as bookbinding was one of the most familiar subjects, he felt sure a great deal of information and profit would be derived from the paper.

The paper read was—

MODERN MACHINE BOOKBINDING.

By GEORGE A. STEPHEN,

Chief Assistant Librarian, St. Pancras Libraries.

The present epoch is pre-eminently an age of machinery, and consequently an age for cheapness. Necessity being the mother of invention, the insatiable desire of the masses for a cheapening of manufactured articles has resulted in the invention of ingenious mechanical contrivances for minimising hand-labour in all departments of manufacture, including the making of books.

Machine bookbinding was solely a product of the nineteenth century. At the time of the Great Exhibition of the works of Industry of all Nations in 1851 it was in its infancy, yet the jurors of the bookbinding section were jubilant at the great strides which they considered had then been made. The following extract from the jury's report concisely states the extent of machine bookbinding at that time:—

"Mr. Burn, of Hatton Garden, first introduced rolling machines to supersede hammering. The

iron printing presses of Hopkinson and others were altered to form arming-presses, by which block gilding, blind tooling, and embossing can be effected with accuracy and rapidity. Leather covers, embossed in elaborate and beautiful patterns by means of powerful fly-presses, were introduced by M. Thouvenin, of Paris, about twenty-five years ago; and almost simultaneously in this country by Messrs. Remnant & Co., and by Mr. De la Rue, who were quickly followed by others. Embossed calico was also introduced about the same period by Mr. De la Rue. Hydraulic presses, instead of the old wooden screw presses; Wilson's cutting machines, which superseded the old plough; the cutting-tables with shears, invented by Mr. Warren de la Rue, and now applied to squaring and cutting millboards for book-covers—all these means and contrivances, indispensable to large establishments, prove that machinery is one of the elements necessary to enable a binder on a large scale to carry on that business successfully."

Since the Great Exhibition the incessant demand of the public for cheap books, and the acute competition of publishers and authors, have combined to stimulate mechanicians to produce machines for the efficient execution of almost every process in printing and book-binding, and the natural result to-day is a plethora of books, good, bad and indifferent.

Before proceeding to describe the various processes in edition binding, it may be of interest to refer briefly to some of the machines used for pamphlet and magazine work. For pamphlet work wire is generally preferred by binders on account of the economic advantages to be derived from its use. There are on the market a great variety of wire-stitching and binding machines for stitching single sections through the centre of the fold, or for binding together several sections by stabbing them through the left-hand side. The greatest thickness a wire-stitching machine can pierce is $1\frac{5}{8}$ inches; this extraordinary work is accomplished by a machine made by Mr. Aug. Brehmer. Thread-stitching machines are rapidly displacing wire-stitching machines for certain classes of pamphlet work. The Elliott, Brehmer and Martini thread-stitching machines effectively stitch pamphlets up to about a quarter-inch in thickness, through

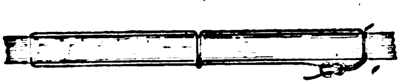

FIG. 1.

the fold or through the side; they are fitted with mechanical devices which make the holes, draw the thread through them, tie a tight reef-knot, cut the thread, and pick up the end of the thread again for the next pamphlet. A machine-made stitch can easily be recognised, as the knot is always tied at one end of the stitch, as shown in Fig. 1, whereas in hand-stitching it is invariably tied in the centre of the stitch.

For periodicals, such as *The Graphic*, Messrs. Harrild's "Graphic" folding machine is used; this machine will fold, inset, cover and stitch with two wire staples, two sixteen-page sheets, one four-page inset and a four-page wrapper, delivering the whole, folded and stitched, ready for trimming. It will also fold and stitch one whole sheet of sixteen pages, half sheet of eight pages, quarter sheet of four pages, with the cover, at one operation; or two half sheets, one quarter sheet, with a four-page or eight-page wrapper. The machine can be altered from whole sheet to half sheet, or from two whole sheets to two half sheets, or *vice versa*, while it is running.

The present method of securing the leaves of the *Strand Magazine* has caused considerable comment, favourable and otherwise. The binding is done entirely by an ingenious machine, known as the Sheridan "Perfect Binder," working at a rate averaging about 1,400 copies per hour; this machine, which has revolutionised the methods of binding magazines, secures the leaves by processes similar to those of the india-rubber binding, patented many years ago by Mr. Hancock. After a complete magazine, minus the cover, has been placed between one of the thirty pairs of jaws, it travels round the machine, and during its progress the following operations are effected: the edges of the folds of the sections are cut off; the edges are roughened to prepare them for receiving the adhesive; the adhesive, a strip of mull, and the cover are then applied in rapid succession; and the magazine is finally delivered upon a receiving table. The magazines are allowed to stand for several hours until the adhesive has set, and then they are trimmed by a cutting machine in the ordinary way.

In edition binding several of the processes continue to be done by hand in most English binderies, but as machines have been constructed for almost all processes, handwork will not be described in the following account. The first operation in edition binding is folding, for which many machines have been constructed; some of them are fed by hand, while others have a self-feeding attachment. The principle on which the folding of the sheets is effected by most of the machines is very similar; the sheet is placed beneath a folding-blade, correct register being obtained by feeding according to guides, or to "points" or small slits; the blade descends

and presses the sheet between two rollers which make one fold; the sheet is then automatically carried to another pair of rollers and folded again, and this process is repeated until the desired number of folds has been made, when the folded section is delivered into a receptacle at the bottom of the machine. Some of the machines insert one section within another before delivering them.

After the sheets have been folded into sections they are tied up in bundles to prevent the different sections being mixed; this work is generally accomplished with the aid of a bundling press, by which the sections can be tied up in bundles of equal size under great pressure, and then stored in the least possible space.

If the book is to contain plates or maps, they are tipped (*i.e.*, pasted) to their respective sections, and the end-papers are attached to the first and last sections of the book. There are machines even for this work, and they accomplish it with a neatness and speed that are truly astonishing. Brehmer's end-sheet pasting machine for attaching end-papers or plates to sections is simple and effective; the operator feeds a section and the end-paper or plate to two flaps, and the machine brings them together, applies the adhesive, presses them, and delivers the combined section. An American machine of more complex construction is known as the Lewis end-papering machine; this is designed to cut, fold, and tip on end-papers to the first and last sections of a book concurrently.

The next process is "gathering." For this process there are several different machines, the action of some of which, such as Mercer's, Juengst and Son's, Plimpton's, and Gullberg and Smith's, is similar; piles of the sections which are to constitute complete books are placed in a series of boxes, from which they are automatically withdrawn and delivered on to an endless band which travels in front of the boxes; by the time the band has travelled across the machine a complete set of sections has been obtained, and it is only necessary for the set to be removed by the girl. Mr. Oscar Friedheim's machine, invented in 1908 by Mr. James Abel, occupies considerably less space than those with travelling bands; it consists of a series of ten trays attached to two endless chains on sprocket wheels carried by two shafts mounted on a frame. The sections are placed in the trays, each of which is arranged to take piles of six sections side by side, and a girl is placed on either side of the machine to gather the sections as the trays rise and fall. The "Express" collator of Messrs. Walker Bros. occupies about the same amount of floor space as Friedheim's machine, viz., six feet square. It consists of a rotating cabinet having three tiers, each of which is divided into sixteen compartments to take sections of the size of an imperial folio, but more compartments may easily be provided for sections of smaller size, by rearranging the partitions. During each revolution the machine stops eight, twelve or sixteen times to enable the gatherers (four or six of whom can sit around the machine) to extract a section from the compartment in each of the three tiers directly in front of them.

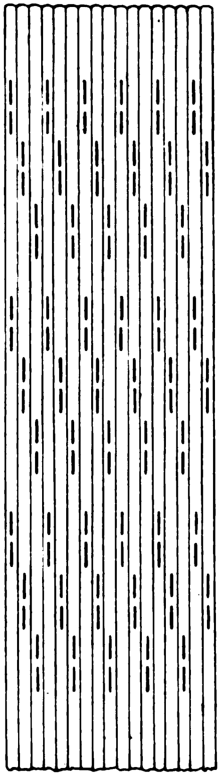

FIG. 2.

The book must next be collated to see that all the sections are in their proper sequence, and that none are in duplicate or missing. The book after being collated is ready for the important operation of sewing, the process upon which the durability of a book so largely depends. Wire and thread are both used for the sewing of books, but in this country the latter material is now used for practically all letterpress books. In Germany, however, books are commonly sewn with wire, and there are many wire-sewn books, including Baedeker's important guides, to which very little objection can be made from the

points of view of serviceability and durability. In wire-sewn books the sections are attached to a common foundation of mull, canvas, or tapes, by staples which are driven through the section (from the inside) and the back fabric, and then clinched at the back. Baedeker's guides and Brockhaus' Encyclopædia are sewn on Brehmer's wire book-sewing machine, which is a typical one. This machine inserts the staples in adjoining sections in different positions, as shown in Fig. 2, in order to reduce the swell in the back of the book; thus two or three times as many rows of staples appear on the back of the book as there are staples in each section; for the sake

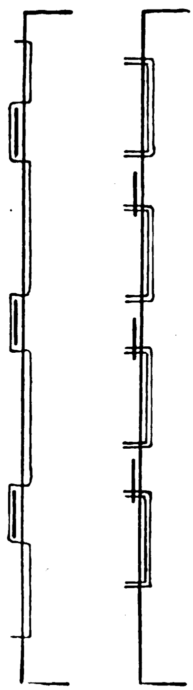

Fig. 3.

of clearness the back fabric is not shown in the illustration. This method of sewing with wire is quite strong, but, as wire does not yield as readily as thread, wire-sewn books are usually less pliable than books sewn with thread, and therefore they are disapproved. With much use the leaves of wire-sewn books are more liable to become loose than those sewn with thread, because the two or three small staples used only secure the leaves to the back fabric to the extent of about 1½ inches, whereas leaves sewn with thread are generally secured about three-quarters of their entire length. The greatest objection to wire-sewn books, however, lies in the fact that sooner or later the wire will rust and rot the paper and the back fabric to which the book is secured, so that the book will fall to pieces, and cannot be rebound without first repairing every fold. Doubtless, if only alumenoid wire were used, this latter objection would be removed, but its price is almost prohibitive.

In England and in America thread book-sewing machines are used almost exclusively for commercial bookbinding. There are now several efficient machines, each of which is adapted for several different kinds of work. By the use of one or other of these machines, books may be sewn on the principles known as "all along" and "two sheets on," the sewing may be plain, through mull, through or over tapes, or over cords, and the stitches may be of different lengths. The principle of machine book-sewing differs essentially from hand-sewing; with one exception the machines sew inside the sections with double thread, and when sewing "all along" as many threads are used as there are to be stitches in a section. In hand-sewing one

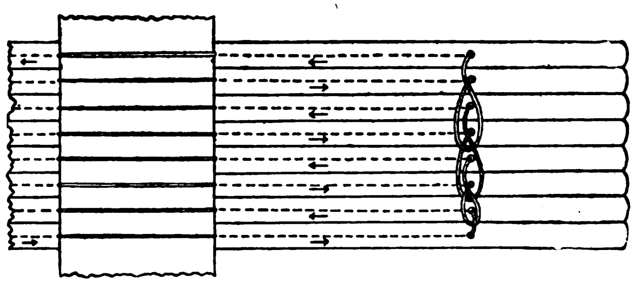

Fig. 4.

continuous thread is used which goes vertically through the whole length of each section, as shown at *A* in Fig. 3. In machine-sewing each length of thread in a given section is independent of the adjacent length, as shown at *B* in Fig. 3, the sections being united by a series of threads passing horizontally along the back of the book. Each thread in a machine-sewn book is inter-looped with itself, and embodied in each is a chain-stitch which the makers of the machines erroneously term a kettle-stitch. Machine-sewing is quite good, and is advantageous because the threads are held under even tension, and, being independent, a section cannot come out of a book until every stitch in the section has been severed; whereas in a hand-sewn book, if the thread be broken, not only will the section come out of the book, but the whole sewing will become loose. The machine chain-stitch, however, is not so strong as the hand-made kettle-stitch (Fig. 4), as may be seen by comparing the two Figs. 4 and 8, but as each machine-stitch

embodies a chain-stitch, the additional chain-stitches in a machine-sewn book compensate for any inferiority in this respect. In operation most of the book-sewing machines are similar; the section to be sewn is placed over an arm carrying punches which make holes in the sections to facilitate the ingress and egress of the needles, and the arm brings the section under several needles and hooks which sew the section.

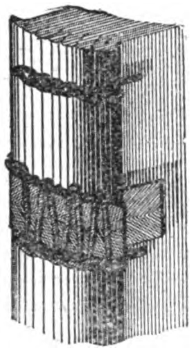

Fig. 5.

The Smyth book-sewing machines are of two kinds, the needles of which are curved, their curvature determining the length of the stitch; the one style has four feeding-arms designed for rapid work, and the other style has a single feeding-arm. Of the various styles of sewing done by the Smyth machines the following are selected for illustration:—Fig. 5 shows the style of

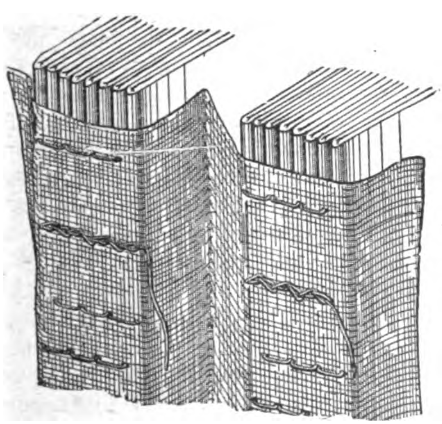

Fig. 6.

sewing done by the improved No. 3 machine (which has four arms) when sewing over tape; it will be observed that the two series of stitches are connected by an auxiliary thread (called a braiding thread), which holds down the tape. Fig. 6 is a sectional view of two books sewn through mull on the "two sheets on" principle as they come from the No. 7 Smyth machine, with the sewing-thread between them cut, but the mull uncut.

Brehmer's machines are of the single-arm type. One of them is different from all other book-sewing machines, as it sews with *single* thread "all along" inside the sections. This machine, unfortunately, cuts the head and tail of each section while sewing, as shown in Fig. 7, for the purpose of allowing a continuous thread to pass from one section to another in such a manner that the threads will not be cut by the guillotine when the edges of the book are trimmed. The

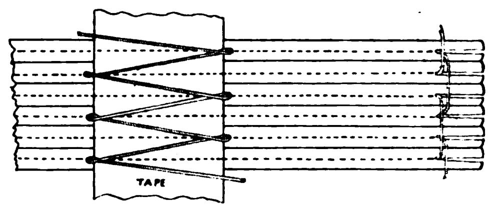

Fig. 7.

use of this machine should, therefore, be confined to "books which are no books"—to borrow a phrase from Charles Lamb—such as large directories and extra-thick books which it is desirable to sew with single thread in order to reduce to a minimum the swell in the back of the book caused by the thread. Three other book-sewing machines are made by Brehmer, and these are much to be preferred for ordinary edition binding. They sew with double thread, and use straight needles, which are adjustable so that the distance between the stitches and also the length of stitch may be varied. An illustration (Fig. 8) is given of the kind of sewing

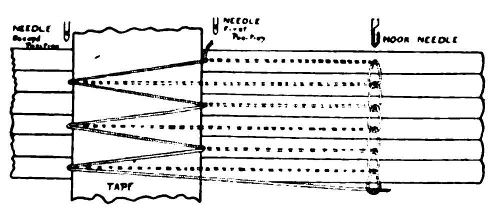

Fig. 8.

done by the No. 38 machine when sewing "all along" over tapes; the stitches in the adjoining sections are of different lengths, due to the automatic working of the needles, which carry the threads in a zig-zag direction over the tapes. The No. 33 machine is adapted for heavier work, and when sewing over tapes the threads are carried over the tapes in a double zig-zag direction to give additional strength. Fig. 9 illustrates the plain (or French) sewing done by this machine when adapted for sewing on the "two sheets on" principle.

The Martini book-sewing machines are also of the single-arm type, and are equipped with straight needles. The Martini machine, known as National No. 1, is arranged only for plain

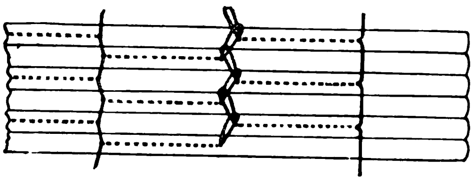

FIG. 9.

sewing or for sewing through mull or tape, or both together; this machine produces stitches of one length only, viz., $1\frac{1}{8}$ inches, and when sewing through tape the stitches are as illustrated at Fig. 10. The National No. 2 machine has several improvements; it will sew over tapes or cords, in addition to the styles of sewing done by the No. 1 machine; it will make stitches of several different lengths, and it has an automatic adjustable saddle which permits sections of different thicknesses to be sewn without any adjustment on the part of the operator. The stitches produced by this machine when sewing over tapes are similar to the zig-zag stitches shown at Fig. 8.

Messrs. Edler and Co. handle three book-sewing machines, which are known respectively as the "Universal," the "Victory," and the "Rapid" book-sewing machines. The Universal machine does various kinds of sewing, and makes stitches of three different lengths; when sewing over tapes the stitches are similar to those of

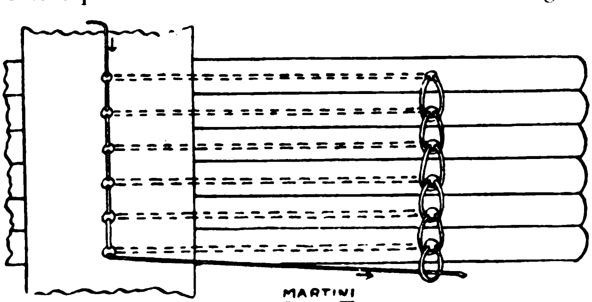

FIG. 10.

the Brehmer No. 38 machine, illustrated at Fig. 8. The Victory machine is similar in construction to the Universal machine, but is adapted for heavier work; instead of making an ordinary zig-zag stitch it makes a combined stitch of $2\frac{1}{2}$ inches and plain stitch of $\frac{15}{16}$ inch, or combined stitch of $3\frac{3}{4}$ inches and plain stitch of $1\frac{1}{2}$ inch, as illustrated at Fig. 11. The Rapid machine is for light work, and is so arranged that the sewing devices require no adjustment when changing from one job to another.

A machine specially adapted for sewing account books and books of a similar nature is

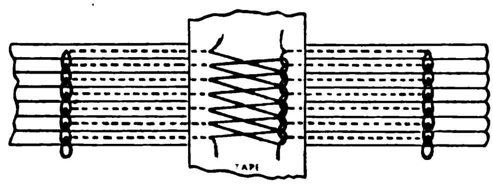

FIG. 11.

sold by Messrs. Marriott and Stewart; this machine works without stabbing needles, it sews over tape or canvas, or through tape, and produces a pearl stitch, as shown at Fig. 12.

After sewing, the book is taken to the nipping or smashing machine and inserted between the upper and lower platens; the pressing is rapidly and thoroughly effected by the rising and falling of the upper one. The back of the book is then "glued up" by hand to hold the sections together while the cutting or trimming of the

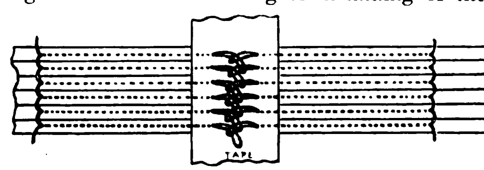

FIG. 12.

edges is performed; the back is brushed over with hot glue, which is, or should be, worked well in between the sections. Whether the edges of a book should be cut or not by the publishers' binder is a moot question; probably most librarians prefer the binder to do the work. There is an almost endless variety of cutting machines; some of them have only one knife, others have two knives, and others, again, have three. Most of the guillotines work upon a similar principle: a pile of books is correctly placed by means of a gauge on the bed of the machine; the operator starts the machine, and it automatically completes the cycle of operations; the work is clamped under heavy pressure; the knife descends, cutting one edge, and returns to its original position; the clamp releases the work, and the machine stops in order that the work may be removed. The "Duplex" trimmer is equipped with two knives which act automatically and simultaneously, and with turntables upon which two piles of

books are placed back to back. An enormous output in a short time is effected by the machines having three knives; these are respectively called the "Seybold," the "Oswego," and "August Fomm's" continuous book-trimmers. The construction of these three machines is similar, the essential features being a rotary table divided into four sections, and three knives which act simultaneously and automatically, so that at every quarter-revolution of the table a pile of books is delivered having the three edges cut. The latest machine for cutting the three edges of books, introduced by Smyth-Horne, Ltd., is a novel one, and exceedingly rapid. The operator, at intervals, feeds a handful of books to the gate of the machine; the machine itself jogs and presses the work, cuts the three edges at one operation, then unclamps the work, and discharges it into the receiving trough. For trimming books that are to have deckle edges, the Mercer continuous book-trimming machine

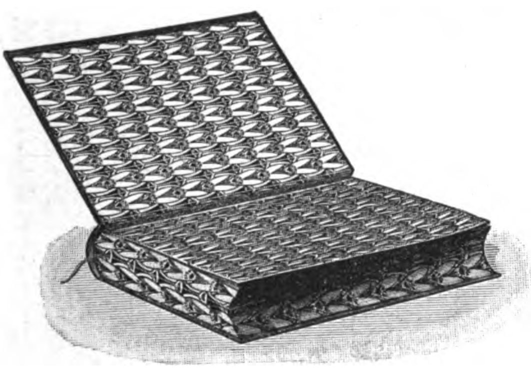

FIG. 13.

is employed; this machine has a circular knife which cuts off the projecting edges of the leaves as the books are automatically drawn against its edge by means of two horizontal endless chains.

If the edges of the book are to be decorated by gilding, colouring, or marbling, the work is done by hand at this stage of the operations. There is, however, a machine for ornamenting book-edges in imitation of marbled edges; it was brought out in 1908 by Messrs. J. G. Schelter and Giesecke, of Leipzig, and is now used in some Continental binderies. The machine is constructed on the principle of the manufacturers' well-known Phœnix platen printing-machines, and all its operations are automatic. The operator places the book on the platen, where it is secured by a clamp, and it is then carried forward to the printing surface, which has meanwhile been inked by the forme rollers; during the return motion of the platen the book is unclamped and lifted so as to allow of its being easily and quickly removed by the operator. By the use of this machine it is possible to ornament the edges in several colours, and with a design to correspond to the end-papers and binding of the book (as shown at Fig. 13), thereby giving the book a uniform finish.

The book is now rounded and backed by a rounding and backing machine. The Crawley machine rounds and backs each book by one continuous operation; the operator simply places the book between a pair of rounding rollers, and the machine does the rest of the work. The rounding and backing machines are capable of doing their work in a thorough and effective manner if they are set accurately and are manipulated by intelligent workmen, but carelessness on the part of the operators may easily ruin the folds of the sections. After the book leaves the rounding and backing machine its back should receive a second coating of glue, a strip of mull should be attached, and a strip of tough paper should be put on top of this. Unfortunately, however, the mull is frequently attached during the first glueing of the back, with the result that most of the strands on the back are severed by the rounding and backing machine, and the strength of the back lining simply depends upon the strip of paper.

While the preceding operations are being performed, the book-cover or "case" is made in another department of the bindery. The work of case-making is now done entirely by machinery. The first stage in the making of a cover is to cut the boards to the required size; this is done by a rotary cutting machine driven by power. There are two machines in general use for case-making, namely, the Sheridan case-maker and the Smyth case-maker; the construction and working of these machines are different, but they both automatically glue the cloth, apply the boards and lining, and turn in the edges of the cloth, thereby making a complete case. For the Smyth case-maker a roll of cloth must first be cut into rectangular sheets of the correct size for the cases, but for the Sheridan case-maker the ordinary roll must be cut into a roll of a width requisite to the cases, which is then fixed to the machine.

The book-cover is now ready to be lettered with its title, and to be ornamented. Cloth book-covers may be decorated in various ways —by blind stamping, embossing, blocking in gold, white or coloured foils, or alloyed metals, and printing in colour, or by a combination of some of these processes. If the cover is to be

decorated simply by blocking in blind or gold, or by printing in one colour, only a single die is necessary; but if the cover is to be decorated in gold and one or several colours, a separate die is required for the gold and each colour, unless the colours are to be blended by applying the colour in bands up and down or across the cover. For blocking in "blind" or in gold, or for printing in colour, dies or blocks cut in relief are used; for stamping in relief, a die of hardened brass cut in intaglio, and a counter die, made up of millboard, sugar-paper, or *papier-maché* are necessary. There is an enormous variety of machines for doing the work of blocking and printing. Most of the blocking presses work in similar manner: the block is fixed to an upper plate, situated under a heating-box kept at correct temperature by gas-jets; the cover, after having had the gold-leaf laid on, is placed on the lower platen, and it is then brought into contact with the die which gives the impression and fixes the gold-leaf. The superfluous gold is afterwards wiped off, leaving the ornamentation visible. Colour-work is done without heat, and frequently platen printing-presses, specially constructed for the purpose, are used. Another form of book-cover decoration in vogue is that consisting of a paper illustration, usually forming a central panel, attached to the cover which has previously been stamped to form a depression to receive the print and to protect its surface. This method is to be deprecated, because the paper illustrations soon get very shabby, and, furthermore, the book-cover should not resemble or compete with the illustrations in the book. Attention may be drawn to two other recent methods of book-cover decoration, viz., lithography and the three-colour process. The upper cover of Messrs. A. Constable and Co.'s edition of Oliver Goldsmith's "The Deserted Village," published in 1909, has an excellent reproduction of a charming rustic scene painted by W. Lee Hankey, which was effected by lithographic printing on a cloth which had been specially prepared. The pictorial design on the red cloth cover of H. Strang's "Humphrey Bold" (Henry Frowde and Hodder and Stoughton) was obtained by first blocking a portion of it in white foil, and then applying the three-colour process.

Five or even six different colours are sometimes used in printing book-covers, but more frequently the number of colours is restricted to one or two, with or without the addition of gold, which, of course, lessens the cost of production considerably, as each colour requires a separate printing. From an artistic point of view the restriction of colours is commendable, because the "painty" appearance which covers printed in several colours frequently have is avoided.

The present excellence of the designs of publishers' book-covers and end-papers is due partly to the arts and crafts movement (indelibly associated with the names of William Morris and Walter Crane), which has done so much for the practical revival of sincere design and handicraft. Within recent years a distinct school of book-cover designers has arisen, and artists in other and wider fields of decorative art, such as Walter Crane and Sir Hubert von Herkomer, have contributed their quota to book-cover decoration. There is an enormous variety in book-cover designs and end-papers which may be classified into four main groups: (1) æsthetic, (2) symbolic,

FIG. 14.—Designed by A. A. TURBAYNE.
By permission of Messrs. T. C. & E. C. Jack.

(3) heraldic, and (4) pictorial. The aim of the designer of an æsthetic book-cover is merely to create a design that will decorate with ornament the rectangular cover without any apparent connection with the subject-matter of the book. A. A. Turbayne's cover-design* for Messrs. T. C. and E. C. Jack's edition of Lamb's "Tales from Shakespeare," herein reproduced, is a beautiful example of this class. The aim of the designer of a symbolic cover is to suggest by imagery the purport of the book. Illustrations of two typical examples of this class are given. Walter Crane's felicities of design are seen to advantage

* The blocks of the cover-designs by A. A. Turbayne, W. Pogany, G. W. Eve, A. Rackham, C. E. Dawson, and J. Hassall, illustrated herein, have been kindly lent by Messrs. A. W. Penrose and Co., the proprietors of the 'Pictorial Annual."

on his cover for Spenser's famous collection of pastorals entitled "The Shepheard's Calender" (Harper and Brothers), which depicts a shepherd and his appurtenances, and the symbols of the zodiacal constellations. Willy Pogany's treatment of grape leaves and roses on the cover of Messrs. Harrap's edition of the "Rubáiyát" of Omar Khayyám is strikingly original, and effectively symbolises Fitzgerald's quatrains of the Persian astronomer-poet. A good example (see Fig. 17) of an heraldic book-cover is that of G. W. Eve's "Heraldry as Art" (B. T. Batsford), designed by the author, which depicts a lion rampant, supporting a banner bearing a Tudor rose.

Pictorial covers are very numerous on children's books, and they are also plentiful on books intended for "children of a larger growth." Pictorial designs aim to illustrate clearly the contents of books; usually a

pictorial cover either portrays one or more of the characters, or it illustrates an important scene in the book. Arthur Rackham's successful design for Mr. Wm. Heinemann's edition of

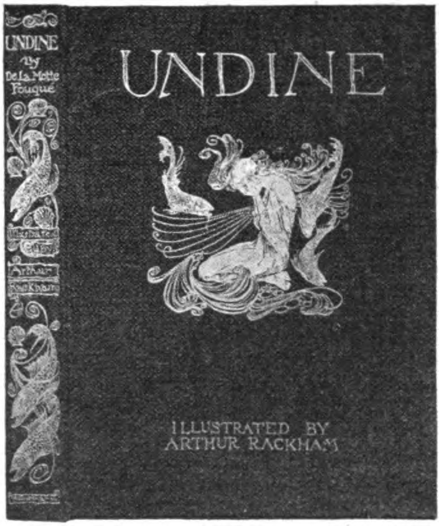

FIG. 18.—Designed by ARTHUR RACKHAM.

De la Motte Fouqué's "Undine" (herein reproduced) is an excellent example of a pictorial cover; the design, blocked in gold on blue cloth, portrays the water spirit in her grief, whose name gives the book its title. Charles E. Dawson's cover-design for "Six Women" (T. W. Laurie) is illustrated herein as an example

of a pictorial cover, the silhouette figures of which indicate the title of the book; it is also an example of a successful colour-scheme which secures the effect of three printings by one

working, the colour gradations being obtained by dividing the ink duct of the printing press. The famous "poster-man," John Hassall, has produced a large number of pictorial designs, many of which are humorous; an illustration is given of his ludicrous cover-design for "A Cockney in Arcadia" (George Allen and Sons), which cannot fail to arrest attention and arouse curiosity as to the contents of the book—the principal object of the pictorial cover.

Many decorative end-papers are specially designed for use in a particular book, and frequently they are the work of the illustrator, who also designs the book-cover, thus ensuring harmony in the decorative scheme; other end-papers are intended for a series of books, and thus, besides being decorative, serve to show the relationship of the books in a series. A familiar example of the latter class is R. L. Knowles' pleasing symbolic end-paper for Messrs. Dent's "Everyman's Library," which is admirably adapted for a comprehensive series of volumes of the great and live literature of all time; the Gothic character of the design is in keeping with the mediæval morality play from which the motto is taken, and the twirling ornament is suggestive of Fortune's wheel, amidst which is the calm, matronly figure of Wisdom, holding a branch of the tree of knowledge and the scroll of learning. Walter Crane, who considers that end-papers should not compete with the illustrations proper, but should be delicately suggestive of the character and contents of the book, is very partial to end-papers having

repeating patterns. A noteworthy example of this artist's work is the end-paper for his "Ideals in Art" (George Bell and Sons), the

design of which (see Fig. 22) consists of vertical rows of conventional laurel leaves alternating with rows of ancient lamps. Edmund

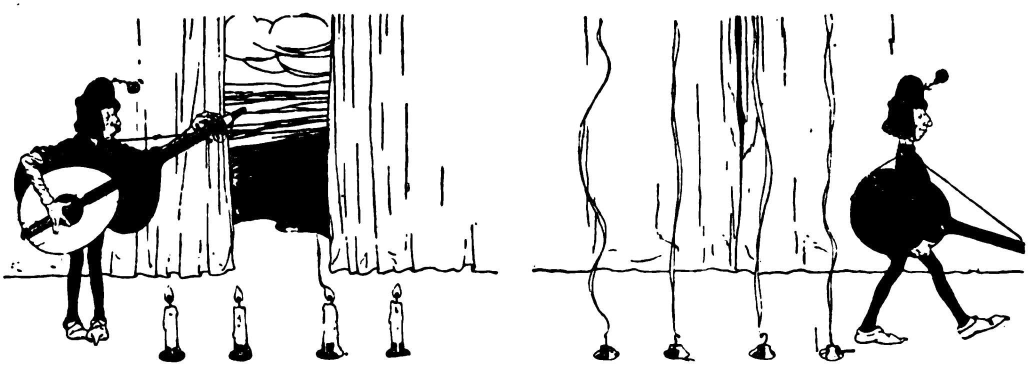

FIG. 23.—End-papers for "LYRICS: PATHETIC AND HUMOROUS." Designed by EDMUND DULAC.
By permission of Messrs. F. Warne & Co.

Dulac's "Lyrics: Pathetic and Humorous" (F. Warne and Co.), has two good end-papers (see Fig. 23), depicting a musician, grave and gay, which form an excellent introduction and conclusion to this clever nonsense book. As the love of children for pictures is insatiable, pictorial end-papers are specially appropriate for children's books. L. Leslie Brooke has successfully grouped the principal characters of some of the most popular rhymes in the "Nursery Rhyme Book" (F. Warne and Co.), edited by Andrew Lang; from the illustration of this end-paper it will be observed that the figures unmistakably suggest the verses of Tweedledum and Tweedledee, Four and Twenty Black Birds, Ride a Cock-horse, Little Jack Horner, Three Blind Mice, Little Miss Muffet, and Mother Goose.

To resume the description of edition binding. The book-cover, having been ornamented, is attached to the book by a casing-in machine.

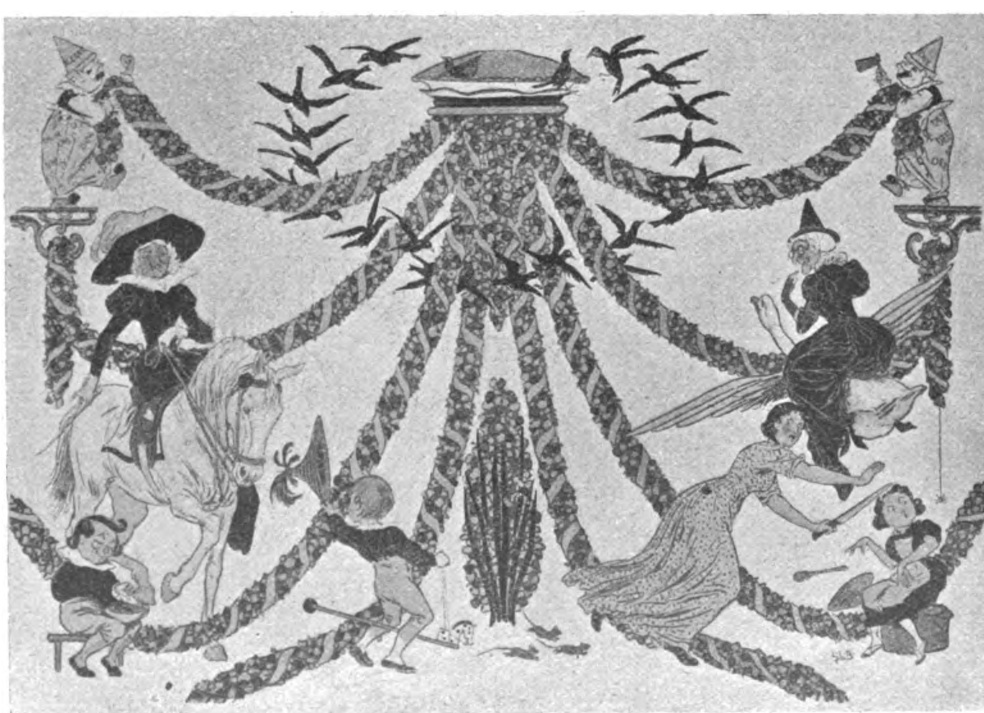

FIG. 24.—End-paper for "NURSERY RHYME BOOK." Designed by L. LESLIE BROOKE.
By permission of Messrs. F. Warne & Co.

If the Smyth machine is used, the book is placed on a radial arm which brings it into the centre of the machine; two rollers apply the paste to either side of the book; a cover is automatically placed over it and forced into the joints, and the sides are pressed before the book is removed by the operator. If the Parkside machine is used, the book is placed in a guide and pushed on to a book-blade; it is then lowered into the machine to receive a coat of paste from a pair of pasting-plates, during which time a cover has been advanced from the magazine, had its back rounded, and then been placed above the book; as the book ascends, it rises into and lifts the cover, and the cased book is then removed by the operator. As the books are removed from the casing-in machine, they are conveyed to a hydraulic standing press, in which they are stacked and pressed for several hours. Finally, the books are removed to receive their wrappers, and they are then ready for the publisher.

From the preceding account of edition binding it should be evident that machine binding has come to stay, and that satisfactory work can be done by the machines if they are permitted to work at their maximum efficiency. Unfortunately, owing to the acute stress of competition between publishers and the demand for cheap books by the public—who cannot or who will not make any distinction between immediate and ultimate advantage—the publishers are practically compelled to avail themselves of every means which tends to lessen the cost of production. The inferior physical qualities of books at the present day must not be attributed primarily to the wholesale bookbinder, as he simply estimates for that for which he is asked, and, if the prices are cut very fine, one cannot expect him to turn out good work. The responsibility lies with the publisher, who is generally more concerned with low prices than with quality and serviceability; even when he is prepared to pay a fair price for a binding* he oftentimes handicaps the binder severely by giving him books to bind that are printed on the detestable featherweight paper, or the equally execrable heavily-loaded art paper, both of which preclude the binder from doing satisfactory work. Featherweight paper cannot be sewn tightly because if much tension is imparted to the thread it would tear the paper, neither can featherweight paper be properly pressed, as this would considerably reduce the bulk of the book, and thus frustrate the publisher's object to delude book-purchasers into believing that they were receiving in exchange for their cash a book containing a large amount of reading matter. These books are generally provided with very attractive covers, as the publishers are well aware that, as in Shakespeare's time, "the world is still deceiv'd with ornament." It is sometimes facetiously suggested that a kindly Providence invented featherweight paper for modern books because the majority of them have only a slender claim to survive another generation. Whether a new book has a strong claim or not to literary merit, its worst fate, as a writer in the *Pall Mall Gazette* recently pointed out, is to carry, like a victim of cancer or consumption, the seeds of its dissolution within itself. There are hundreds of valuable books, including costly reference books, printed on inferior paper which are a standing disgrace to the publishers who issue them. The heavily-loaded art paper, which has come into vogue as a result of the extensive use of half-tone and colour blocks, is also a serious defect of modern book production for several reasons. It cannot be bound satisfactorily by the usual methods of commercial bookbinding; after a book composed of this paper has been subjected to slight usage, the surface of the paper flakes off from its meagre basis of fibre, the glue on the back of the book cracks and breaks away from the paper, and thus the whole book becomes loose, and the sections speedily break in their folds. From the readers' point of view, books printed on this paper are inconveniently heavy to handle, the paper is unpleasant to the touch, it is dazzling to the eye, and one leaf sticks to another upon the slightest application of moisture; furthermore, unless the paper experts are wrong, it is doomed to rot speedily.

So far as publishers' bindings of the present day are concerned, their defects are generally assignable to one or more of the following items:—

Materials.

1. The use of thread, tapes, cords, and mull of inferior quality.

2. Sewing or stitching with wire that is not rust-proof. (Wire-sewing is not much used in England for bookwork, but pamphlets are commonly stitched or stabbed with wire staples.)

3. The use of inferior glue or glue of the wrong consistency.

4. The use of inferior cloth which is neither fast to sunlight nor to water, and which soon becomes faded or discoloured and shabby.

* Publishers' books are "cased," not "bound," but the familiar term "binding" has been used herein instead of "casing."

5. The use of cheap metal foils instead of gold leaf.

6. The use of unsuitable blocking inks.

7. The use of white or coloured foils which easily rub off when the books are handled a few times.

Methods.

1. Sewing with thread to which insufficient tension is imparted, thereby resulting in "loose" sewing. (Of course, if the tension be too great, the thread would tear the paper and would also result in loose sewing.)

2. Sewing on the "two sheets on" principle, which considerably decreases the strength of the binding; furthermore, sections sewn by machine on this principle are usually perforated by the punching devices, as if the sections were to be sewn on the "all along" principle, so that there are several unnecessary holes in each section, which, besides being unsightly, decrease the tensile strength of the paper, and frequently allow the glue to penetrate into the middle of the sections.

3. Sewing on the "all along" principle on an insufficient number of tapes or cords, and with less than the maximum number of stitches. In some cases the tapes or cords are dispensed with, and the books simply sewn on to mull of poor quality.

4. Fixing the back lining of mull to the book prior to the rounding and backing operations. This practice frequently results in many of the strands of the mull being severed by the rounding and backing machine; and if the backing plate of this machine is not properly adjusted the paper at the folds is crushed and broken.

5. Tipping plates, maps, etc., or other single leaves with paste, instead of guarding them round the adjoining section.

6. Cutting the slips (*i.e.*, the ends of the tapes or cords) too short, and cutting the mull of a less width than is necessary to make a strong joint.

7. The defective execution of the casing-in operation. (This may either be due to the application of an insufficient quantity of paste at the joints, or to the inaccurate placing of the cover on the book.)

8. Paper illustrations and paper titles on the covers.

9. Square-backed books which cause the fore-edges to assume a convex shape.

10. General looseness of the book due to insufficient pressing in the standing press.

Some of these defects are to be found in almost all publishers' bindings, which are consequently very unsatisfactory. In a public library the average life of a publishers' binding before being repaired is about thirty issues. When deciding upon the kind of binding (apart from the decoration of the cover), publishers do not seem to take into consideration the selling price of the book, and provide a binding commensurate with it; books published at 25*s.* often have bindings no better than those on books published at 6*s.* Especially is this true of expensive scientific and technical works for which a small demand is anticipated; many of these, being translations, cost the publisher comparatively little. Presumably, a publisher estimates the probable number of copies required by public libraries and scientific bodies, bases his selling price accordingly, and depends for his profits upon sales to private individuals. To provide a flimsy binding for such books is sheer shortsightedness and stupidity on the publisher's part, because if a public library decide to purchase these books, the extra cost of a satisfactory binding would not be noticed or resented.

So far as works of fiction and cheap books generally are concerned, book-purchasers as a rule receive an adequate return for their money, and doubtless the bindings serve their purpose sufficiently well when books are only handled a few times; but the bindings are quite inefficient for service in public or school libraries. The report of the Books and Apparatus Sub-Committee to the Education Committee of the London County Council on the first day of this month is apposite:—

"We are somewhat disappointed to find that a large number of the new books do not reach the standard of excellence which would justify our recommending that they should be placed on the Council's list. This criticism applies not only to the subject-matter, but to the paper, the binding, the illustrations, and the covers. We think it would be well for the publishers to consider whether it would not be advisable to issue books bound in plain cloth covers, unobtrusive in colour, and with clear gilt lettering, rather than in covers which are gaudy in colour, inartistic in design, or which bear poor and unnecessary illustrations."

It is encouraging to note that during the past two or three years the American Library Association's Committee on Binding has succeeded in inducing several of the leading American publishers to issue some of their important and popular books in a strong binding, suitable for library requirements, at a small additional cost, generally about ten cents, and fifteen cents for some of the larger volumes.

In June, 1908, no less than 112 works in reinforced bindings prepared by different publishers were exhibited at the Annual Conference of the American Library Association, and since that date additional works have been issued; some of these bindings conform completely to the following specifications prepared by the American Library Association, while others conform in certain particulars only:—

1. The first and last signatures guarded with muslin.

2. End-sheets made of good paper and reinforced with a muslin joint to be sewed on as a signature.

3. Best quality of cotton thread to be used, and volume to be sewed on three tapes.

4. Thin strong muslin or canton flannel to be used on the back instead of the ordinary super [*i.e.*, mull].

5. Use some kind of strong buckram for a cover instead of the ordinary trade cover.

In the main the books were sewn and cased by machinery; in some cases the books were bound in a good strong buckram, while in others the cloth for the ordinary trade edition was used. The Chairman of the Binding Committee of the American Library Association, who has tested the reinforced bindings in his library, has recently informed me that he considers "there is no comparison between the durability of the good special binding and the ordinary publishers' binding." In no case had he to rebind the special bindings in buckram made by one large publisher, while other books had to be rebound because the ordinary trade cloths did not stand the hard wear to which the books were subjected, although the sewing was perfectly sound. The American publishers' reinforced bindings have given complete satisfaction to librarians. In a letter published in *Public Libraries*, the Librarian of the Jacksonville Public Library, U.S.A., stated that a copy of F. H. Smith's "Tides of Barnegat" (Charles Scribner's Sons) had circulated in his library "142 times without a single visit to the repair room." A specimen copy of this book in my possession is bound in buckram, is machine-sewn on two tapes, has end-papers with cloth joints sewn on as a section, and the title and author's name are lettered in gold on the back.

In this country three publishing firms have emulated the example of the American publishers. The firms of Henry Frowde and Hodder and Stoughton combined in 1909 for the purpose of publishing a series of "Oxford Books for Children," some of which were issued as an experiment in special library bindings of quarter pigskin and pluviusin. Considerable improvements were made in these special library bindings a few months ago, and they now possess the essential features of serviceable library bindings. The books are obtainable in quarter pigskin or morocco, and whole legal buckram or Imperial morocco cloth, and the chief characteristics of these bindings, which approximate to the usual library bindings, are as follows:—The books are bound from the sheets; the books are sewn on four or five tapes on the "all along" principle—the smaller volumes by machine, and the larger by hand; the first and last sections are lined in their folds with jaconet; the illustrations are guarded with jaconet round the adjoining section, and sewn through; the end-papers have linen joints; the books have French joints; flexible glue is used on the backs; the boards are good quality millboards with blunted corners; the books are boldly lettered in gold on the back with the title and author's name, and neatly finished with blind fillets.

The firms of Thomas Nelson and Sons, and J. M. Dent and Sons both issued, in the spring of last year, some of their publications in reinforced bindings. Messrs. Nelson's experiment consisted in issuing several of their 2*s.* net novels in a special binding at an extra cost of sixpence per copy, the special features of which are:—the book is machine-sewn with strong thread on the "all along" principle, on three tapes which are of good length; the first and last sections are lined in their outer folds with linen; the book has linen joints; the cloth is strong, and the boards are stout grey boards; and the title and author's name are boldly lettered on the back.

Messrs. Dent and Sons' venture is much more extensive, the whole of the five hundred volumes comprising their world-famous "Everyman's Library" being obtainable in two styles of library binding: (1) bound in a strong linen-faced cloth at 1*s.* 6*d.* net per volume; (2) bound in quarter pigskin at 2*s.* net per volume. The special features of these bindings are:—each book is machine-sewn with strong thread on the "all along" principle on three strong tapes; the back is rendered flexible by the use of a special glue, and the back lining of mull is of good quality; the end-papers are completely lined with mull, and they are passed round the first two and last two sections of the book; the boards are strong millboards; the title and author's name are clearly lettered on the back, and the cover is devoid of ornament.

In the provision of special library bindings for expensive works the Cambridge University Press has decided, within the last few weeks, to take the initiative; copies of the new edition of the "Encyclopædia Britannica" will be bound in half morocco in accordance with specifications prepared by the British Library Association, and in whole "Legal Buckram" in accordance with the American Library Association's specifications. The specifications of the British Library Association provide, amongst other items, for strong machine-sewing with unbleached thread on unbleached linen tapes; the guarding of plates; end-papers with cloth joints; lining the first and last sections with linen; millboards instead of strawboards; French joints; Winterbottom's "Imperial morocco cloth" fast finish; and hard grained morocco, in conformity with the Royal Society of Arts' specifications.

These pioneer efforts in the direction of serviceable publishers' bindings are greatly encouraging to the Book Production Committee of the British Library Association, which is now formulating a series of standards regarding the typography, paper, and binding of books in the hope that they will be accepted by the leading publishers as a basis on which modern book production shall be carried on. This committee has almost completed its investigations, and its report will, in all probability, be published during the present year. In the meantime I have permission to quote the committee's two provisional specifications for publishers' cased work as they are at present formulated.

Specification I.

Publishers' Cased Work Generally.

1. Books to be sewn with strong thread.
2. Books to be sewn "one sheet on" on strong tapes; at least three tapes to be used for crown octavos, four for royal octavos, and an increased number of tapes for books of larger size. Two of the tapes to be placed not more than one inch from the head and tail of book, and the slips to be of good length.

Note.—In the case of extra-thick volumes printed on thin paper it may be necessary to sew "two sheets on."

3. All single leaves and plates to be guarded round the adjoining section and sewn through. Or, when the plates are few, they may be pulled on paper with the inner margin extra wide in order to allow the paper to be folded round the adjoining section.
4. End-papers to be of good quality.
5. Flexible glue to be used in glueing up.
6. The lining to be of a strong open fabric.
7. Good quality cloth of fast colour to be used.
8. Books to be lettered on back with title and author's name at least. Ink used for the decoration of covers to be fast.

Specification II.

Publishers' Cased Work for Libraries.

1. Books to be sewn with unbleached thread.
2. Books to be sewn "one sheet on" on unbleached linen tapes; at least three tapes to be used for crown octavos, four for demy octavos, and a porportionate increase in the number of tapes for books of larger size. Two of the tapes to be placed not more than one inch from the head and tail of book, and the slips to be of good length.

Note.—In the case of extra-thick volumes printed on thin paper it may be necessary to sew "two sheets on."

3. All single leaves and plates to be guarded round the adjoining section and sewn through. Or, when the plates are few, they may be pulled on paper with the inner margin extra wide in order to allow the paper to be folded round the adjoining section.
4. The first and last sections to be guarded with linen; fine cambric for books printed on thin paper.
5. End-papers with cloth joint sewn as a separate section.
6. Flexible glue to be used in glueing up.
7. The lining to be of a strong open fabric.
8. Good quality boards with a strip of strong liner glued over the slips inside the case.
9. Good quality cloth of fast colour to be used.
10. Books to be lettered on back with title and author's name at least. Ink used for the decoration of covers to be fast.

In the opinion of the Book Production Committee the first specification represents the minimum requirements of all publishers' bindings. The second specification is presented as a statement of the requirements of books that are likely to be subjected to considerable wear in libraries; for books bound in accordance with this specification librarians would be prepared to pay an extra cost commensurate with the quality of the binding. While the general adoption of these reasonable and practicable specifications would ensure durable "cased" books which would redound to the credit of the publishers and would give satisfaction to their patrons, it should not be inferred that the bindings of such books would be the *ne plus ultra* of commercial bookbinding.

In the interest of sound book production, specifications are required for all the materials

used in commercial bookbinding, in addition to specifications for superior book-paper. The Royal Society of Arts did a great service when it appointed a committee to investigate the causes of the decay of modern leather bindings, and to indicate the best methods of preparing leather for bookbinding; and the committee's published report has had a salutary effect on the manufacture of leather, for which all librarians and bookbinders are grateful. But leather is only one of several materials which are of importance in connection with the durability of bindings. Tapes, cords, thread, glue, and cloth are all factors of prime importance in bookbinding. The Report of the Committee on Leather for Bookbinding certainly recommends the use of unbleached linen tapes and unbleached linen thread, but no reasons are offered in support of the recommendations; unbleached materials are obviously preferable to bleached ones, but it seems to be a moot point as to whether linen is superior to cotton. With regard to thread, it is questionable whether first quality cotton thread, apart from its cheapness, is more suitable than linen thread. It is true that the tensile strength of linen thread when new is much greater than that of cotton thread, but linen thread frays more readily than cotton thread. It has been seriously contended by an eminent gentleman connected with the bookbinding industry that the application of glue to the back of a book affects linen thread (and linen tapes) much more than it does cotton, and that linen thread rots and deteriorates to a considerably greater extent than does cotton thread; further, it is stated that dealers (in America, at any rate) find it impracticable to carry any considerable quantity of linen thread on their shelves, because in a very few months it becomes dry and brittle, and retains only a fraction of its original strength. Here, then, is a matter that requires investigation. Tests should be made as to the tensile and fraying strains of linen and cotton threads, and their relative tendency to become dry and brittle, and to rot under the action of glue; and specifications should be formulated as to their suitability for various classes of work.

With regard to glues used in bookbinding, it is desirable that tests should be made as to their chemical composition and their properties, and formulæ should be prepared in order that no injurious ingredients should be included that would be injurious to the thread, tapes, book-cloth or leather. The glue used on the backs of books has an important bearing on their strength and flexibility; therefore tests should be made to ascertain the affinity of glue—which should be flexible—for the various classes of book-paper, and its liability to crack.

Although there are in existence some satisfactory grades of book-cloth which are fast, or relatively fast, either to water or sunlight, these are, unfortunately, not in extensive use for publishers' work. Most of the book-cloths used for publishers' bindings are unsatisfactory; usually they are not durable, they are neither fast to water nor to sunlight, and in some instances they speedily become discoloured. The discoloration, which is most observable on certain blue cloths, does not seem to be due to exposure to sunlight; whether it is due to the kind of dyes used, the action of the glue used in attaching it to the boards, or to any chemicals in the boards, remains to be ascertained.

As book-cloth is the material most extensively used for the covering of books, it is very desirable that the various grades should conform to certain specifications, so that publishers might be in a position to select for a particular book a cloth most suited to the usage it is likely to receive. A standard and popular novel, for example, requires a more serviceable cloth than an ephemeral novel of slight popularity, and a large and heavy technical work usually requires a more durable cloth than either.

In America the Bureau of Standards made important physical and chemical tests regarding the durability of certain selected book-cloths, which resulted in the publication, in 1909, of valuable specifications. The objects of the chemical tests were (1) to determine the extent to which the samples of book-cloths submitted were subject to the attack of insects, and to ascertain, if possible, the conditions favouring or discouraging such attacks, and a means of preventing them; (2) to determine the relative liability to change of colour when exposed to light. The objects of the physical tests were to determine the following physical properties, viz., weight, thickness, number of threads per 2 cm., absorption of moisture, expansion and contraction with changes in moisture, friction when pressed together, durability with respect to folding, durability with respect to rubbing, tensile strength, and stretch. The specifications formulated as a result of these severe tests are given herein as an appendix. Already the two largest book-cloth manufacturers in America are producing cloths in accordance with these specifications; these cloths are being extensively used in America on books

that require a strong durable cloth, and they have already found favour in this country. The only adverse criticism that has been applied to these cloths is that they are not fast to water. As these specifications were originally formulated with the view of obtaining a satisfactory cloth for the binding of Government publications and reference works of a similar character, the question of fastness to water was comparatively insignificant. It is very desirable, however, that cloth on books which are carried to and from libraries in all weathers should be fast to water, in addition to being fast to sunlight. So far as I am aware, no cloths at present meet these requirements.

The standardisation of book-cloths in Great Britain is quite practicable, and it is worthy of the attention of the Royal Society of Arts. The Society could prosecute inquiries and obtain suitable materials for testing, and so forth, and it could employ the National Physical Laboratory to make the actual tests, as it possesses much of the necessary apparatus. It might be advisable to formulate three specifications for book-cloths: (1) for cheap cloth for ordinary book-work; (2) for a medium cloth for superior books; and (3) for a good cloth for library books and others that require a strong durable cloth. Similar tests to those of the Bureau of Standards might be made, but special attention should be given to the relative advantages of cotton cloths as compared with linen cloths, and to the attacks of British and foreign insects; tests should be made regarding the effects of water on the colour of the cloth, the effects of the products of combustion on the cloth, and the behaviour of the cloth in regard to germ cultures.

If the Royal Society of Arts would undertake the work herein suggested, a powerful impetus would be given to sound book production. The publishers would then have reliable standards for their guidance in the production of satisfactory books, for which librarians and others would be prepared to pay a fair compensation; the publishers would receive the cordial co-operation of the paper-maker, the printer, the manufacturers of materials, and the binder; and with this consummation British books would become renowned for their intrinsic value in addition to their artistic qualities.

[NOTE.—The paper was illustrated by an exhibition of modern commercial bookbinding, which included specimens of the binding of the *Strand Magazine* by the Sheridan "Perfect Binder," the various kinds of machine book-sewing, book-edge decoration by the Phœnix platen machine, case-making by machinery, and the blocking and colour printing of book-covers. The exhibits also comprised book-cloths made by J. Bancroft and Sons, and the Holliston Mills, in accordance with the specifications of the Bureau of Standards, Washington, U.S.A.; fast finish cloths made by the Winterbottom Book Cloth Co.; a set of blocks and book-covers to illustrate the seven stages in the decoration of the book-cover for "The Shepheard's Calender," designed by Walter Crane; specimen volumes in accordance with the Library Association's provisional specifications prepared under the supervision of Mr. Douglas Cockerell; reinforced publisher's bindings by J. M. Dent and Sons, Thomas Nelson and Sons, Henry Frowde, and Hodder and Stoughton, Charles Scribner's Sons, and the Houghton Mifflin Co., U.S.A.; specimen volumes of the special library binding for the new edition of the "Encyclopædia Britannica"; samples of flexible glue; and a collection of about 200 decorative end-papers and 200 book covers designed by English, American, and foreign artists. A number of the specimens were kindly lent by James Burn and Co., Ltd., of London and Esher.

The paper was also illustrated by lantern-slides of the principal machines used in commercial bookbinding, diagrams of various kinds of machine book-sewing, and a series of coloured slides, made by the recent process of the "Thames" Colour Plate Company, of typical book-covers and end-papers.]

APPENDIX.

SPECIFICATIONS OF THE BUREAU OF STANDARDS, U.S.A., FOR BOOK-CLOTH.

Fabric.—The fabric shall be made from first quality staple cotton, uniformly woven and of a grade known as "firsts." The weave shall be two up and two down in the warp, and one up and one down in the weft. The grey cloth shall consist of from 33–36 threads per centimeter (85–90 per inch) in the warp, and 12–15 threads per centimeter (30–38 per inch) in the weft. The surface shall be finished smooth and hard, and show no tendency to stick when folded upon itself.

Thickness, Tensile Strength and Weight.—The thickness of the finished fabric shall not exceed ·30 millimeter (0·012 inch), or be less than ·20 millimeter (0·008 inch). The tensile strength of the

grey cloth shall not be less than 18 kilograms per centimeter (100 lbs. per inch) of width in the warp, and 9 kilograms per centimeter (50 lbs. per inch) of width in the weft. The average value for the warp and weft in the finished fabric must show an increase over the average value for the warp and weft in the grey cloth of at least 10 per cent. of the strength of the grey cloth. The finished fabric, when dry, shall weigh not more than 260 grams per square meter (0·5 lb. per square yard), or less than 200 grams per square meter (0·4 lb. per yard).

Absorption of Moisture.—At a normal relative air humidity of 65 per cent. it shall not absorb more than 5 per cent. of moisture, or expand (an average of both directions) to exceed ·45 per cent., and when subjected in a closed case to a saturated atmosphere for two hours, at a temperature of 20° C. (68° F.), shall not absorb more than 10 per cent. of moisture, or expand (an average of both directions) to exceed 2 per cent. All increases to be computed on the basis of the dry weight and dimensions.

Folding Endurance.—The folding endurance as determined by the Schopper folder shall be not less than 65,000 double folds for the warp, and not less than 10,000 for the weft.

Colour.—Before coating, the fabric must be dyed with a purely mineral or inorganic colour (such as iron salts), so as to imitate the colour of the finished cloth, but somewhat lighter in shade, so as to give the desired "linen" effect. All coal-tar, aniline, vegetable, or other organic dyes and lakes, must be strictly excluded from both fabric and coating, even in traces. The following substances must be also excluded: Chrome yellow and other chromates, ultramarine, browns containing bituminous or other organic matter, compounds of lead and arsenic. The colour of the finished fabric should be slightly darker than the standard sample, which will be furnished on application, and it must not show the slightest change of colour after exposure under prescribed conditions to direct sunlight, or to the action of ammonia gas, sulphuretted-hydrogen gas, sulphur-dioxide gas, or illuminating gas.

Resistance to Mould and Insects.—The finished fabric shall be immune to the growth of mould or the attack of insects.

NOTE.—For the present some latitude will be allowed in the enforcement of this requirement, since definite knowledge of the causes and the methods of prevention are still lacking. Experiments have shown that book cloths have been produced which meet the requirements.

Tests.—Physical and chemical tests to verify the properties required by these specifications will be made according to the standard methods for testing book cloths as used by the Bureau of Standards, copies of which can be obtained on application.

DISCUSSION.

The CHAIRMAN (Mr. John Murray), in opening the discussion, said that though he had not actually bound a book with his own hands, he had been responsible for a very great deal of binding, and therefore the subject was of intense personal interest to him. The more one heard of the shortcomings to which Mr. Stephen had referred, the more one felt that the two points of view from which the subject might be considered, namely, that of the book-lover and the book-user, were widely different. Those who were book-lovers must have felt, in looking at some of the old bindings with studs and ornamental silver plates, that though they were works of art in themselves, they were absolutely inappropriate for books. A book in its normal state was not to be laid on a table, or put in a bookseller's shop, but it should be put on a shelf along with other loved and cherished friends, and books bound in the rough, unkindly bindings to which he had referred were almost impossible for that purpose. He had in his collection one or two of the old chained books, which were a constant source of anxiety, because they had to be kept by themselves; otherwise their neighbours suffered from their contact. One point in regard to the beauty of binding which the author had not touched upon was that the first requisite in a book which could be admired inside and outside was the imposition of the text. He had seen ostensibly beautiful books which were entirely spoiled from faults of that kind. In considering, as a publisher, the question whether books should have cut edges or not, it was necessary to take into consideration that question, because if the book was a good book issued in a cloth binding, many book-lovers would in due course have it bound in leather, when the head had to be cut a second time; if this was done a trifle too much, the book was spoiled for ever. He had some first editions of Shakespeare in which the head had been so cut that the title at the top of the page was half cut away, and in handling these books he felt this almost like a hurt to himself. Years ago, when his father issued one of Darwin's works, at the time when the question was first discussed as to whether the edges should be cut or not, although many thousand copies were subscribed for, he did not think 10 per cent. were ordered with cut edges. In those days it was the fashion to have books uncut. A man who loved a book liked to cut the edges with a paper-knife and to look at the rough edges, the thought being present in his mind that some day the book would be bound according to his own taste. But people at present lived in a hasty age, and very few of them were in favour of the uncut edge. The author had very properly criticised the publishers, who generally were held responsible for much that they had not done. Personally he should feel sorry if, in a discussion upon books, the publishers did not come in for their full share of blame, because he was so accustomed to it that he

rather liked it. The publishers were accused of being responsible for bad bindings, for a certain amount of stupidity, and for a desire to delude book-purchasers. He assured the audience that cheap bindings were a grievous necessity, although it was heart-rending to the publishers. If publishers tried to turn out a book well on the best paper, with the best binding, they got no thanks for it; the public did not appreciate it. We were living in an age when there was a craze for cheapness. It was no doubt an excellent maxim that people should buy in the cheapest market, but the other essential, inseparable condition must not be lost sight of, that it was sometimes wise to sell in the dearest market, and by buying in the cheapest market the selling market might be altogether lost. Books were put on the market at such a price that some publishers did not care to turn out such cheap work. He was interested to hear from the author that the London County Council had complained of the standard at present adopted in regard to the paper and binding of a large number of new books; but the L.C.C. were in a great measure responsible, for if the publishers raised the price of the books the authorities would not look at them. He strongly contended that it was the force of public opinion nowadays which compelled the bindings to be cheap. The criticism which he had made as to the unsuitability of bindings covered with nails or silver applied to some of the beautiful designs of books at present produced. To book-lovers the normal and proper position of a book was on a shelf, and not on a table, and a pictorial lithographed side was, to his mind, utterly out of place. It was only an advertisement, which might show up very well in a bookseller's shop, but personally he felt inclined to have a book rebound which had a picture on its side. Some very beautiful, startling and realistic designs had been produced, but he felt that for real beauty of design something was required which was not realistic but which was conventional. For instance, there were the beautiful designs displayed in the British Museum; and above all there was the magnificent book which was issued to the public some years ago of the bindings in the Royal Library at Windsor, from which it would be seen that binding, like printing, began at its very zenith. Publishers could not nowadays compete with Caxton or Sweynheim and Pannertz. Those people used better materials; they cherished their art; they turned out everything almost like an old missal manuscript, the very best work being put into it; and the paper 400 years afterwards was almost as good as the day it was turned out of the mill. A book-lover handled such a book with the feeling that it was a treasure. But nowadays the public did not appreciate that sort of work; books were looked upon, not as articles to be treasured, but as things to be used and thrown aside. With regard to wire binding, he altogether abhorred its use for books. It could be used very well for a pamphlet which was thrown away after it was read, but to use it for binding books was, he thought, wrong. He was delighted to hear Mr. Stephen's statements with regard to books standing wear and tear so well. From experience, he thought everyone would agree that schoolboys were pretty hard on books, but the books which had to stand the roughest and hardest wear were those which were placed in the hands of choir-boys. He was the first to advise the binding of hymn-books with pigskin backs and cloth and leather sides and corners, because that was the strongest form of binding in existence. For durable leather bindings Russia leather should, in particular, be eschewed; in fact, very few leathers could be used for this purpose.

Mr. W. E. Doubleday stated that among the defects of modern bookbinding to which the author had not referred was the glazed cloth, the surface of which got into a sticky condition, so that when a person handled the book the imprint of his fingers remained on it for ever afterwards. Part of the responsibility for the present defects in bookbinding rested with the public, because they were not prepared to pay for the improvements which might be effected at very little extra cost; and part of the responsibility rested with the publishers, who had a habit of charging quite out of proportion for the cost of any improvements which were effected. For instance, the prices asked for the cloth cases which the publishers produced for binding works which had appeared in serial form, were sometimes more than the amount charged by a bookbinder for binding the book in sound leather in accordance with the recommendations of the Royal Society of Arts. If the publishers would have the courage to adopt a superior form of binding, he thought they would find the public ready to respond to any moderate charge which might be made for the improvement. If, on the other hand, the price was altogether out of proportion, the undertaking was foredoomed to failure. As a book-lover and librarian he wished to call attention to the abominable character of some of the paper used in the production of books, particularly the spongy paper—the most difficult of all forms with which the binder had to deal. One London firm published nearly all its books upon spongy paper, the books being very tightly bound in cloth; and the life of those books, so far as that binding was concerned, was over after the books had gone out six or seven times. He hoped the publishers would not continue the use of such wood-pulp papers, as binders assured him that it was physically impossible to bind soundly a book made with that particular paper, because there was no substance for holding the thread. With regard to the question of printing imposition, he wished to utter a note of warning with regard to mechanical type-setting, which was coming more and more into practice. Part of the trouble might be due to the paper, but he knew of many books in which the mechanically-set type was a source of constant irritation to the eye. He hoped some improvement would be

effected, so that mechanically-set type might more closely resemble the hand-set type, of which it was a very imperfect imitation. He hoped that, as a result of the meeting, the Society would take up the question of the improvement of the physical appearance of books and the life of books as it had taken up the leather question. If it did so, he believed the attention not only of librarians but of the public would be directed to the question; and if a fair appeal was made to the public he thought they would surprise Mr. Murray by the response they were willing to make to an improvement at a reasonable price.

Sir GEORGE BIRDWOOD, K.C.I.E., regretted that the author did not in the earlier part of his paper condemn illustrated backs, which were very wonderful in their technical aspects, but from an artistic point of view were simply detestable. Bookbinding should be as plain as possible, and of all forms of bookbinding he preferred the old tree-calf or the mottled-calf. It was a great pleasure to him to hear the Chairman agree with the criticisms of the author in regard to the defects of the cheaper processes of bookbinding. As a botanist and medical man who had practised a great deal in India, he thought he could explain why cotton thread lasted better than linen. Cotton fibre was hollow, while linen fibre was solid. Linen fibre did not absorb moisture; the moisture clung to the outside of linen and tended to rot it very rapidly. Cotton fibre and cotton clothing absorbed a great deal of moisture, and the natives of India wore cotton clothing exclusively, unless they wore silk, and therefore they never caught cold. It was the English people, who wore linen and woollen underclothing, that always caught cold. He thought the demand of the public for cheap books could be met, not only in the way indicated by the last speaker, but also by following the French method of publishing books. The French publishers issued books in two forms—the first in a paper wrapper, and the second in superior kinds of leather bindings, at different prices. They secured themselves against loss by communicating with every likely subscriber for the purpose of ascertaining in what form he would like the book bound before it was passed through the press. There was a large public in this country who would buy good books and pay for good bindings, and the publisher could guard himself, at any rate to some extent, against any risk by adopting the French plan, which, it seemed extraordinary to him, was not more known in this country.

Mr. R. A. PEDDIE said that after carefully considering, not only the author's works but other information, it was very difficult indeed to fix the responsibility for the condition of the modern book. In his opinion, books might be divided into two classes: firstly, the cheap books, with regard to which decent condition of production could not be expected; and, in the second place, the books published ranging in price from 12*s*. 6*d*. to 25*s*. The latter class of books had, he was sorry to say, very little more care expended on them than the cheaper books, and it was that class of books which librarians expected to have put before them in a satisfactory condition. A technical book, which was published a little time ago on a particular phase of book production, reached one library in such a state that the pages were only held together by a thread here and there. The book was sent back to the publishers, with the request that a decently-bound copy should be forwarded, and a special copy was bound and sent to the library. That sort of thing unfortunately was continually coming to his notice. It must also be borne in mind that the cost of the more important books was increasing and not decreasing. In a particular book which had been published over a series of years, and of which several volumes of equal size had now appeared, each succeeding volume had been slightly higher in price than the preceding volume. The price was very high to begin with, and he did not think any slight rise that might have taken place in the cost of the materials could justify the increase. He wished to emphasise the author's remarks with regard to book-cloth. Many of those present would recollect the firm of Bentley, which many years ago published a series of novels called the "Standard Library," bound in dark-green cloth, with no ornamentation and perfectly plain lettering on the back. The cloth was of good texture and a thoroughly solid material. On inquiring from a representative of a firm of book-cloth manufacturers whether such a cloth was now produced, he replied, "No, we are never asked for it." That was the secret of the whole thing; the book-cloth manufacturers were prepared to produce the material, but they were never asked for it. Buyers of books ought to insist that books for which they paid the same price as in days gone by should be produced under the old conditions. The ordinary book of the 'sixties or 'seventies was properly sewn; was made of good paper, and not of mechanical wood-pulp paper, and after it had been used for a reasonable length of time was in good condition; but he very much doubted whether a book produced according to ordinary modern methods would be seen in such a condition twenty or thirty years hence. It would be falling to pieces, the back would be off, the cloth would be spotted all over, and it would be rotten from one cover to the other. When publishers charged such high prices for books, he thought they might reasonably be expected to consider the question of putting a little of the price into the book itself, because modern expensive books were not got up in a style commensurate with the price paid for them. The harmony of a German book with its cover was much better thought out than any book that was ornamented and produced in England on a similar basis. Germans did not use the staring reds, violets, and blues that were seen in English books. The majority of English publishers bound the

greater portion of their books in red because it was the colour that attracted, but unfortunately it was the one colour which was not fast. On the other hand, the German publisher used a cloth of good texture, and the whole book was produced in a workmanlike fashion. He would like to see English publishers adopt what was good from the German school, and harmonize it with the best practice of the English school. Although he agreed with the author's remarks with regard to wire sewing, there was one point in its favour, namely, that Baedeker's Guide Books, which received the hardest possible usage, were sewn with wire, and it seemed to be particularly effective for that class of book, because it was a very rare thing to find a Baedeker with loose leaves, unless it was an old copy.

Mr. G. A. Stephen, in reply, after thanking the audience for the kind manner in which they had received his paper, and tendering his thanks to the Chairman for presiding over the meeting and for the valuable remarks he had contributed to the discussion, said that although he had shown some typical specimens of the exceedingly ornate book-covers of the present day, he was very careful not to commend the practice. He simply showed them as illustrations of modern bookbinding. In regard to Mr. Peddie's remarks, he thought the publisher probably paid the binder as much at the present time for the binding of the book as he did formerly, but unfortunately an undue proportion of the amount went in payments for the design and decoration of the cover. The artist obtained his fee; blocks had to be cut for the reproduction of the design, which was exceedingly costly, and the binding proper suffered thereby. Mr. Doubleday had disagreed with his (the author's) statement that the average life of a book in a publisher's cover was thirty issues. He agreed with Mr. Doubleday's criticism, but he had purposely placed that figure high in the paper. Some books tumbled to pieces after being issued five or six times, but he thought it was unfair to press the point unduly, and therefore considered that thirty issues were sufficient to rub into the publishers at the present time. The meeting was indebted to Sir George Birdwood for his interesting remarks on cotton and linen, which might supply the reason for the superiority of cotton thread in certain classes of commercial bookbinding. He did not think, however, the French method of publishing books would be acceptable in this country, because there were many more public libraries in England than in France, and it would be exceedingly costly for libraries to buy their books in paper covers and have to pay 1*s*. 3*d*. or 1*s*. 6*d*. to get them bound before they could be put into circulation. In addition to that, it would prevent books being put as quickly into circulation as was at present the case; a month or six weeks' delay would probably result. Mr. Peddie had spoken somewhat favourably of the wire-sewing of Baedeker's Guides, but it must be borne in mind that those books had very little rounding and backing, and the covers were very thin and pliable. He had examined some large German books in the Patent Office Library, and found that the wire made the books so unwieldy that when they were backed in the machine there were quite a number of ugly creases in the folds.

The Chairman, in proposing a hearty vote of thanks to the author for his interesting and instructive paper, said the exchange of views which had taken place would be most useful and advantageous, and if only a little could be done to induce the public to appreciate good materials in the making, binding, and illustration of a book, as well as in the text, the paper would not have been in vain.

The resolution of thanks was carried unanimously and the meeting terminated.

ARTS AND CRAFTS.

A London School of Arts and Crafts. — The Camberwell School of Arts and Crafts usually holds its annual exhibition at about this time of year, and it is always an interesting event. The show which is now open at the South London Art Gallery in the Peckham-road, and will remain on view until nearly the end of the month, is, of course, not very widely different from its predecessors, but it is none the less very well worth a visit, not only because the work in some departments is in itself deserving of attention, but because the exhibits as a whole give a very good idea of what an up-to-date school of arts and crafts in London does and does not do. It is, from the first, quite plain that it does not do very much in the way of teaching design for manufacture. It is true there are a few pattern-designs on the walls, but they form on the whole one of the least satisfactory features of the exhibition. There is nothing which strikes one as really first-rate (even for students' work), and the patterns as a whole show no very firm grasp of the principles of the subject. The tendency is to make everything all-overish and featureless; and the value of plain spaces, in helping to give at once distinction to a design and rest to the eye, is not by any means generally understood. It may be that design pure and simple cannot be expected to take a very prominent place in a "School of Arts and Crafts," but it seems a pity that a subject which so vitally affects some of the largest industries of the country should not be more popular with the students in the schools of the Metropolis.

The largest and most important group of exhibits is doubtless to be found in the embroidery section, in which a quantity of good and interesting work is to be seen. It includes some very delicate small pieces of work and a good deal of crewel-work in which patterned background

fillings have been employed to good purpose. Some of the designs are quite sufficiently good for their purpose, but in a few cases it is difficult not to think that the student would have been better employed in carrying out a good design by someone else than in executing her own very feeble pattern. It is really waste of labour to expend good needle-work on a bad design, and, though, theoretically, it may be an admirable plan to make students work from their own patterns, the fact remains that quite a number of capable needle-women are by no manner of means designers. There are several pieces of white linen cutwork on which the stitchery is in colours. The effect of this is extremely pleasing, and it leads to very delicate colour schemes. The one or two pieces in which lines of gold thread are added to the coloured stitching are also very effective, but gold thread hardly seems a good material to employ on white linen. Much of the work in type-setting is very satisfactory, both tasteful and restrained. The students have, however, not unnaturally, been much more successful in displaying short titles than in setting up prospectuses and the like containing a great deal of matter. The examples of script and lettering are rather larger in scale than usual, but they are almost without exception well done. It seems rather a pity, however, that the student who elected to write a piece of German should not have chosen a more appropriate form of lettering. The bookbinding, as usual, is very good, and the practice of inlaying in sufficiently large pieces really to affect the design and colour scheme of the cover forms a conspicuous feature in the collection of bindings, which includes also some very good work in blind tooling. There are some workmanlike pieces of plastering, and quite a collection of pots, vases, panels, and windows in simple ornamental leadwork. The cabinet work is tasteful and characterised by a pretty use of small inlay. The drawers, etc., are fastened up so that it is impossible to tell how they run, but they look as if they fitted extremely well. The woodcarving, too, is better this year than it has been before. There is nothing very interesting in the way of stained glass, but the work of the students in the decorating and sign-painting classes is on the whole very promising. Of metalwork on a large scale there is not very much to be seen, but one or two cases of jewellery are on show. The simple work is, some of it, very pretty, but the more ambitious pieces are sometimes rather lacking in accomplishment. The enamel is extremely good. The students seem to be taught to aim at certain definite results, and not to be satisfied with anything short of them. Not only is the more elementary work satisfactory, but the really elaborate picture plaques seem generally to be very successful, and the work throughout is characterised by an appreciation of those qualities which enamel is best fitted to give. To sum up, the work on view at Camberwell, though some of it might be better, is on the whole quite as good as schoolwork can be expected to be. If the lines on which it runs are somewhat too widely divergent from those of the big industries of the country, though the fact is to be deplored, that can hardly be laid to the charge of the students, or even of the teachers of this particular school. The fault, if fault there be, goes farther back.

Women's Craftwork.—Only one room is devoted to craftwork at the exhibition of the Society of Women Artists, and it would be manifestly unfair to judge the merits of an exhibition by a small proportion of the work shown; but as regards the particular kind of art with which these Notes are concerned, it cannot be said that the exhibits at Suffolk-street make one feel that there is any particular reason why women's work wants showing apart from men's. The objects on view certainly do not, as a whole, reach so high a standard as a good deal that is to be seen at places where the work both of men and of women is shown. If one did not know better, the natural inference to draw from this exhibition would be that, except in so far as jewellery was concerned, woman's work in the artistic crafts was almost a negligible quantity. Of jewellery there really is a representative show, and if it does not include any strikingly great work, there is a fair amount that is quite creditable. A good number of women jewellers send work, and the list of exhibitors includes such well-known workers as Mrs. E. Roscoe Mullins, Miss L. Rimmington, and Miss Ethel Virtue. But the exhibition, taken as a whole, fails to justify itself on the arts and crafts side. There are several places in London where equally good work can be seen without going to a special exhibition, and it seems a pity that, if women are going to exhibit as women, they do not take care to get together a collection of objects which will give the public some sort of idea of what good work they are doing. Those of us who know what is being done realise that women form a very important section of the craft-workers of the present day; the ordinary visitor to Suffolk-street might well come away with the idea that their work was about fit for a bazaar.

Truth in Craftsmanship.—The first lecture of a course by various well-known men on the arts connected with building was delivered at Carpenters' Hall on January 25th by Mr. Raffles Davison, who took as his subject, "Truth in Craftsmanship." The lecturer showed by his slides that his sympathies were considerably wider than some of his utterances would have led his audience to expect. And, with two of his contentions, he really went to the root of a good deal that is amiss with the art of the present day. He maintained first, that the truth which we are to look for in artistic work of all kinds is *truth as seen by the artist*, not the purely mechanical truth of a photograph; secondly, that all affectation is contrary to real truth in craftsmanship. The first truth is one which, perhaps, at the present day needs emphasising more in the sphere of pictorial art than of artistic craftsmanship; but when we

come to "affectation," as Mr. Raffles Davison understands it—the affectation which refuses to use modern tools and improvements, and expects to be patted on the back in consequence—we feel that craftsmanship is the main offender. It is true, indeed, that, at any rate so far as a large section of the workers are concerned, the tendency to extol only archaic work has passed away, but there remains a large body of people who look askance at anything not produced as it was some hundreds of years ago; and undoubtedly this demand for affectedly elementary craftsmanship does help to produce a want of sincerity. Let people do simple work, by all means, and plenty of it, but do not let them fall into the error of supposing that accomplishment counts for nothing, or that, however simple the work in hand may be, anything is lost by employing modern methods when they help towards its perfection.

EMPIRE NOTES.

Cotton Growing within the Empire.—In a paper read before the Royal Geographical Society by Mr. T. Howard Reed a few weeks ago, he gives an account of the work of the British Cotton Growing Association, and shows that their statement, that "cotton can be grown within the Empire on a large scale and on a commercial basis" is fully proved. Four districts were specially selected by the Association for demonstration—Nigeria, Uganda, Nyasaland, and the West Indies. The reports of the progress of cotton cultivation in the West Indies are very encouraging. The cotton grown is mainly that known as "sea-island," which has been reintroduced from the islands off the coast of South Carolina. But other varieties are also being cultivated to advantage. Africa, however, affords the most promising field for the cultivation of the variety of cotton most in demand in this country. This especially applies to West Africa, where there are large areas of land possessing a soil and climate specially suited for the purpose, where, indeed, an extensive native industry has been carried on for centuries. On the other side of the continent, in Nyasaland, the first experiments were made in 1901-2. By August of last year the cultivation was said to be "going ahead by leaps and bounds." Uganda also is proving a most promising field. Some difficulties were met with at first, due to the ignorance and inexperience of the natives, but, under careful instruction, these have been overcome, and now, according to Sir Hesketh Bell, the late High Commissioner, Uganda may become "one of the greatest cotton-fields in the Empire." But these are not the only British lands where cotton can be profitably grown, and where efforts for its cultivation are being made. In South Africa, and particularly Rhodesia, good samples are being grown, and, in the latter country, special attention is being given to the subject by the British South Africa Company and the Association. India and Ceylon, which, at present, produce large quantities of short-fibred native cotton, can grow better qualities, and, by Governmental assistance and instruction, efforts to this end are being made, which are likely to result in a large increase of the supplies available from these countries. Australia, also, and New Guinea can grow cotton of good quality, while Borneo, Fiji, the Straits Settlements, the Malay States, the Seychelles, Mauritius, Cyprus, the Maltese islands, and St. Helena, may all become producers. And all are needed, if the requirements of our own trade are to be met within the Empire. To keep pace with our present demand, three and a quarter million bales of raw cotton, each of 500 lbs. weight, are wanted every year. To meet this demand, the continued efforts of the British Cotton Growing Association and the various colonial governments, during eight years, have only succeeded in producing one hundred thousand bales of 400 lbs. each, or one thirty-fourth of the yearly requirements of our Lancashire mills.

Forestry in New South Wales.—Profiting by the example of older countries, the Australian States are doing their utmost to preserve the forest wealth in their possession, before it becomes too late, and to turn the reserves into sources of regular income. The Forestry Department of New South Wales is doing excellent work, as the latest report shows. Since the inauguration of forestry administration in 1877, there has been a total revenue of £703,343 and a total expenditure of £469,653. There was a deficit of £48,274 on the administration up to the end of 1896, and a surplus of £233,690 for the thirteen and a half years ending June 30th, 1910. The Forest Act, which became law in February, 1910, was the first New South Wales measure to deal exclusively with the question of forestry. It promises, says the report, to be a useful working Act, but its principles will have, in time, to be extended, particularly in the direction of larger control over State forests, and in relation to such questions as their leasing and occupation. The total area, included in reserves for the preservation of timber, is now 7,690,771 acres, showing an increase of 216,511 acres in comparison with the figures of 1909. Of this area, about 4,500,000 acres have already been examined, reported on, and scheduled, for permanent retention, under a scheme of classification, and steps are being taken to review further areas comprised in the reservations, with a view to their dedication as State forests, under the Act. Figures furnished by the Customs and Excise Office show that the value of timber imports exceeded that of exports by about £632,000. Altogether £789,701 worth of timber was imported; £704,091 from oversea countries, and £85,610 from other Australian States. The value of the oversea exports of timber, dressed and undressed, amounted to £247,428; and of rough timber to £222,620. The report states that a year of great activity in the timber industry is expected. There are 420 saw-mills at work in the State, which employ 4,465 hands.

Canadian Progress.—The Minister of the Interior at Ottawa has issued a report embodying the following statistics concerning recent progress made in the Dominion. The value of the gold and silver production of 1910 is calculated at over £5,300,000, as compared with £4,700,000 in 1909. The value of last year's bond issues amounts to £46,300,000. This figure includes £14,000,000 issued on behalf of railways. It is interesting to note that 81 per cent. of the aggregate amount of these various issues found a market in Great Britain. No less than 600 million feet of lumber were cut in Ontario alone during the past year. Canadian trade has increased 88 per cent. during the last decade, which compares favourably with the percentage increase in the trade of the United States and Great Britain in the same period, viz., 55 and 38 per cent. respectively.

The Webster Claim in New Zealand.—A notable visitor to this country from New Zealand this year will be the Hon. J. G. Findlay, Attorney-General and Minister of Justice. His visit is in connection with certain Crown cases. The most important of these, and, at the same time, the most interesting, is the famous Webster Claim for £500,000. The history of this claim is quite romantic, originating as far back as 1840. The claimant, Webster, was a citizen of the United States who went to New Zealand and settled at Herekino, on the shores of the Hauraki Gulf. He appears to have been a man gifted with considerable foresight, and seeing, with the advance of settlement, the inevitable rise in land values, he turned his attention to the acquisition of land. By bartering quantities of blankets, fish-hooks, trousers, shirts and tobacco, with the Maori chiefs for land, he became the possessor of a large amount of property. By the Hobson Commission his claim to native lands, beyond a very small area, became void. It was and is maintained, however, that, being a citizen of the United States, the British Crown had no right to dispossess him. The United States Government have taken the matter up, and the case is to be argued before a specially-constituted tribunal agreed upon by the English and American authorities.

A Burmese University.—Education has been making great progress throughout India during the past few years, and many excellent colleges have been established. A Bill has now been introduced by the Burmese Educational Syndicate for the foundation of a university in Burma. The matter has already been brought before the local Government, and will shortly be referred to the Indian Government for its sanction and approval. The university will take as a model the system of the newer universities of this country. It is proposed that the Rangoon College shall form the nucleus; the Baptist College and other future colleges forming an integral part.

NOTES ON BOOKS.

Fables and Fairy Tales for Little Folk. By Mary and Newman Tremearne. Cambridge: W. Heffer & Sons, Ltd. 2*s*. 6*d*. net.

It has been Captain Tremearne's fortune to spend many years in the service of his country in parts of Central Africa where other white men have seldom or never penetrated, and he has used his opportunities to make the most careful study of the people under his sway. Among other subjects, mainly of an anthropological interest, he has devoted much attention to the folk-lore of Hausaland, and he has collected from the natives themselves a very large number of stories, of which some have been published in this *Journal* and some in *Folk-Lore*. In the present volume we have a dozen tales told in the simplest of language, and, though they are related as merely fairy tales, they have a certain anthropological value. All sorts of animals converse together, as in the days of Æsop—lions, hyænas, elephants, hippopotami, and a curious creature—a half-man, bisected vertically in such a way that he has only one arm, one leg, half a head and half a body—whom we do not remember to have met before. Captain and Mrs. Tremearne have done their work well, and the book ought to prove popular with the children for whom it is intended.

Materials of the Painter's Craft. By A. P. Laurie, M.A., D.Sc. London and Edinburgh: T. N. Foulis. 6*s*. net.

The first six of the fourteen chapters into which this book is divided are devoted to the consideration of the methods of painting in ancient times and up to the dawn of the Christian era. Dr. Laurie concludes (mainly from the statements of Pliny) that two distinct methods of painting were employed in classical times, one of which was the "encaustic" process, in which beeswax formed the medium. The methods of this encaustic painting he explains in detail, and some admirable illustrations of modern work executed according to this ancient method accompany the text.

Polygnotus appears to have been one of the first painters to use encaustic technique, and it is a matter of great regret that when the ruins of Delphi were explored no trace of the celebrated paintings by this worker were discovered; otherwise much valuable information as to the methods and durability of encaustic painting might possibly have been gleaned.

Leaving the debatable ground of classical painting, the author passes, in Chapters VII. and VIII., to the history of mural painting. All the literary evidence available, in the manuscripts of Pliny, Vitruvius, Cennini, Theophilus, and other writers, is carefully reviewed and commented upon, and compared with the opinions formed by various workers as the result of scientific examination of specimens. Dr. Laurie comes to the conclusion that there was a distinct difference between the

technique of fresco painting employed in early times and that practised by the mediæval craftsmen.

In the two following chapters the manuscripts of Theophilus and Cennini are respectively discussed, and then, after an all too brief chapter on "Illuminated Manuscripts," which scarcely does justice to the subject, we come to the most valuable part of the book, in which the author puts together and amplifies in the light of further investigations his classic researches on "The Pigments and Vehicles of the Old Masters." This subject is dealt with in three lengthy chapters, in the first of which, "On the Preparation of the Lakes used by the Old Masters," we see how the various organic pigments were developed from the first crude infusion of dye-stuffs used in early times. The various materials from which lakes are prepared are considered in detail, and the author quotes some interesting experiments of his own on the preparation of lakes according to the recipes given in the manuscripts of Cennini and others.

We then come to a chapter "On the Nature and History of Varnishes," in which the probable method of production of mediæval varnishes is investigated. Literary evidence by itself, as the author points out, is practically worthless on this point, owing to the confusion of nomenclature; but, applying the results of careful experiments to the elucidation of such receipts as occur in the old manuscripts, he comes to the general conclusion that the ordinary varnish used until late in the fifteenth century "consisted of a fairly soluble resin—sandarac or mastic—dissolved in linseed oil, with the addition in many cases of a considerable quantity of pica greca (resin)"; and that the use of volatile solvents and balsams did not come in until the sixteenth century.

The last chapter, on "The History of the Oil Medium," contains a large amount of practical information and pertinent suggestion of which no summary can be attempted in the space at our disposal. The author has here a great deal to say on that much-debated question, the nature of the medium used by the Van Eycks in the preparation of their works, and in discussing it he is seen at his best. Finally, he brings all the information he has gleaned from this study of ancient methods of painting to bear on the problem of producing the most durable work, and sums up his conclusions on the last page.

The book is completed by a most comprehensive and valuable bibliography of forty-eight pages. The difficulty of preparing such a bibliography is immense, and the author specifically states that it makes no claim to being exhaustive.

For the most part the book is written in a style that combines clearness and accuracy with interest, but there are occasional lapses into looseness and confliction of statement which could be eliminated with advantage in further editions. One feels, too, that rather too much stress is laid on the literary evidence, as compared with that derived from scientific research, and Dr. Laurie sometimes suffers from the spirit of the antiquary in regarding the statements of all old writers as gospel unless they come into direct conflict with practical evidence. For example, a great deal of space is devoted to the discussion of the evidence to be deduced from the writings of Pliny, to which the author attaches a degree of importance which one is inclined to question. The book is, however, a most welcome addition to the literature of the subject, and deserves the serious study of every artist, although perhaps its value can only be fully appreciated by those with a knowledge of technical matters.

GENERAL NOTES.

Royal Photographic Society's Exhibition.—The Society announces its Fifty-sixth Annual Exhibition, to be held in May next at the Gallery of Prince's Skating Club. For some years this Exhibition was held at the New Gallery in Regent-street, but the demolition of this building deprived the Society of its usual quarters. Last year the Exhibition was held in the smaller gallery of the Royal Society of Painters in Water-Colours, Pall Mall. Certain changes are made in the classification of the Exhibition, which ought to add to its interest, and the Society has also partly reverted to the practice of awarding medals. These are now offered in all sections of the Exhibition, except Section I. (Pictorial Photographs).

Festival of Empire: Fine Art Exhibitions.—The British Fine Art Section of the Festival of Empire will consist of the works of specially invited modern artists in three classes:—(*a*) Paintings in oil; (*b*) Water-colours, pastels, and drawings; (*c*) Etchings and lithographs. This section will be exhibited in the West Galleries of the Crystal Palace. The art of the Overseas Dominions will be represented by collections of pictures from Canada, Australia, New Zealand, and South Africa, housed in the different Government buildings erected in the grounds of the Palace. In addition to these exhibitions there will be a special section devoted to pictures representing scenes and incidents of historical interest, together with portraits of men and women who have played their part in the building, defence and administration of the Empire. This section will include a number of important paintings kindly lent by the Duke of Marlborough from the Blenheim Palace collection.

Test for Fire-Damp.—A card and leaflet have been prepared, by direction of the Secretary of State for the Home Department, for the purpose of affording to persons engaged in mining clear and simple instructions on the subject of testing for fire-damp. The method of testing is the one described by Sir Henry Cunynghame, in the paper read before the Society last November, viz., the observation of the appearance of the "caps" corresponding to different percentages of gas. The

leaflet is intended more especially for the use of the under-officials of mines; the card (which is in a form convenient for carrying in the pocket) more especially for miners. Both card and leaflet contain a coloured illustration showing the appearance of the "cap" corresponding to percentages of 1, 1½, and 2, of fire-damp.

THE LABOUR EXCHANGES.—The Labour Exchanges have now been in operation for a year, the first batch of 63 centres having been opened on February 1st, 1910. There are at present 160 exchanges at work, and it is expected that nearly as many more will eventually be established. The total number of vacancies notified to the exchanges during the eleven months ended December 31st, 1910, was over 450,000, and the number filled was 370,000. Somewhat contrary to general expectation, the exchanges have proved more useful in filling vacancies for skilled workmen than those for unskilled labour. As the exchanges are in constant communication with one another, they are able to do a great deal in filling, with men from other districts, vacancies which cannot be filled locally. Between 2,000 and 3,000 vacancies have recently been filled each month in this way. Great assistance has been rendered to this branch of the work by the power of advancing railway fares conferred by regulations made under the Labour Exchanges Act. In several thousand cases fares have been so advanced, and the bulk of the money —usually deducted from the workman's wages by the employer—has been recovered.

THE SEA-OTTER.—The sea-otter, when full-grown, measures from four to four and a half feet in length, but so loose is the skin that it easily stretches to six feet; and so valuable is the fur that a skin of this size is worth at present between £300 and £400. Needless to say, an animal which offers such a prize as this is eagerly sought after; and in his recently-published work, "In Forbidden Seas," Captain H. J. Snow gives some interesting particulars of his experiences as a hunter of sea-otters. These animals frequent the rocky coast of the North Pacific Ocean, making their homes in the great belts of "kelp" which flourish there. In former days they used to be so tame that they would stand with head and fore-paws out of the water, watching the hunter and his gun, but the terrible persecution to which they have been subjected has rendered them exceedingly shy and difficult of approach. In the Kurile Islands, between 1872 and 1881, the numbers killed varied from 300 to 1,500 a year; from 1882 to 1891 about 1,200 were taken; from 1892 to 1901 about 800 were taken; while from 1902 to 1909 only about 350 were killed. The numbers caught in the Aleutian Islands were, however, much higher, over 58,000 sea-otters having been killed between 1873 and 1896.

EXHIBITION OF PRINTS AND ENGRAVINGS AT ROME.—The eighteenth exhibition of prints and engravings was opened in Rome on January 29th last. It occupies four large rooms in the "R. Galleria d'Arte Antica," and includes a very interesting collection of works of the sixteenth and seventeenth centuries, chiefly by the Old Masters. Albert Dürer, Rembrandt, Salvator Rosa, Stefano della Bella, Canaletto, Grimaldi, Jacopo Bassano, Bril, Domenichino, Swanevelt, Guercino, Poussin, Jan Botha, etc., are well represented. Many rare engravings, especially a female portrait by Mengs (recently purchased), are especially worthy of mention.

COMO AT THE TURIN EXHIBITION, 1911.—The silk manufacturers of Como have wisely decided to make a collective exhibit of their products at the Turin Exhibition. No expense is being spared to make the show worthy of the best traditions of the silk industry of Lombardy. A special building is being erected in the grounds, and every effort is being made to render it one of the chief attractions of the exhibition. Eminent artists are engaged in illustrating "The History of Dress" during the fifteenth, sixteenth, seventeenth and eighteenth centuries, which were so especially rich in colour and variety. A collection of antique fabrics should prove especially interesting. It is needless to say that modern manufactures will not be neglected, and the silk stuffs for which the province of Como is so justly celebrated will be well represented, while silk in all the various stages of manufacture and processes of production will be shown with great completeness. The opening of the Turin Exhibition by the King of Italy will take place on the 29th April next.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 22.—Professor J. WERTHEIMER, B.Sc., B.A., "Water-Finders."

MARCH 1.—Dr. LEONARD HILL, F.R.S., "Caisson Sickness and Compressed Air."

MARCH 8.—JAMES CANTLIE, M.A., M.B., C.M., D.P.H., "Plague and its Dissemination." Sir SHIRLEY FORSTER MURPHY, M.R.C.S., will preside.

Wednesday afternoon, at 4.30 o'clock:—

MARCH 15.—Colonel CHARLES EDWARD CASSAL, V.D., F.I.C., "The Adulteration of Food." The Right Hon. the Lord Mayor of London will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MARCH 16.—CLAUDE HAMILTON ARCHER HILL, I.C.S., C.S.I., C.I.E., "Education in India." The Right Hon. Lord NORTHCOTE, G.C.M.G., G.C.I.E., C.B., will preside.

APRIL 27.—Sir THOMAS HENRY HOLLAND, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord AVEBURY, D.C.L., LL.D., F.R.S., will preside.

MAY 25.—W. R. H. MERK, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

FEBRUARY 28.—The HON. SIR RICHARD SOLOMON, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "The Resources and Problems of the Union of South Africa."

APRIL 4.—Captain R. MUIRHEAD COLLINS, C.M.G., "Australia and her Resources."

MAY 9.—F. WILLIAMS TAYLOR, "Canadian Banking."

CANTOR LECTURES.

Monday Evenings, at 8 o'clock:—

Professor ADRIAN J. BROWN, M.Sc., "Brewing and Modern Science." Four Lectures.

Syllabus.

LECTURE III.—FEBRUARY 20.—"The Mashing Process." The Chemistry of Starch and its Transformation Products—Protein Changes during the Mashing Process.

LECTURE IV.—FEBRUARY 27.—"The Fermentation Process." Previous Treatment of the subject by Dr. G. Salamon in 1888—The Pure Yeast Question in Brewing—Zymase and Modern Views of Alcoholic Fermentation—Nitrogen Assimilation—The so-called "secondary" products of Fermentation, etc.—Conclusion.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 20...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor Adrian J. Brown, "Brewing and Modern Science." (Lecture III.)

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. J. L. Nickisson, "The Government Horse Breeding Scheme from a Farmer's Point of View."

Bibliographical, 20, Hanover-square, W., 5 p.m. Mr. G. F. Barwick, "The Magazines of the Nineteenth Century."

Surveyors, 12, Great George-street, S.W., 4 p.m. Mr. F. J. Lloyd, "Sugar Beet: Will it Pay to Grow it in Great Britain?"

Victoria Institute, St. Martin's Vestry Hall, St. Martin's-place, W.C., 4.30 p.m. Rev. F. Baylis, "Science in Relation to Christian Missions."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. T. Fyfe, "Germany and the Germans."

TUESDAY, FEBRUARY 21...Statistical, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Messrs. M. Greenwood, Jun., and R. H. Candy, "The Fatality of Fractures of the Lower Extremity and of Lobar Pneumonia. A Study of Hospital Mortality Rates, 1751-1901."

Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Dr. C. W. Saleeby, "The Foundations of Eugenics."

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. W. Mott, "Heredity." (Lecture VI.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. W. T. Douglass's paper, "Coast-Erosion."

Photographic, 35, Russell-square, W.C., 8 p.m. Exhibition of Prints by Members of Affiliated Societies, with Notes by Mr. W. J. Morgan.

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Dr. H. G. Plimmer, "Report on the Deaths which occurred in the Zoological Gardens during 1910." 2. Mr. R. Lydekker, "On *Tragelaphus Buxtoni*, an Antelope from Abyssinia." 3. Mr. E. G. Boulenger, "A Contribution to the Study of the Variations of the Common Salamander (*Salamandra maculosa*)." 4. Mr. G. A. Boulenger, "On a Collection of Fishes from the Lake Ngami Basin, Bechuanaland." 5. Dr. F. D. Welch, "Observations on different Gibbons of the Genus *Hylobates* now or recently Living in the Society's Gardens, and on a *Symphalangus syndactylus*, with Notes on Skins in the Natural History Museum."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. G. H. Scholefield, "The Origins of the New Zealand Nation."

WEDNESDAY, FEBRUARY 22...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Professor J. Wertheimer, "Water-Finders."

Geological, Burlington House, W., 8 p.m. 1. Mr. R. H. Rastall, "The Geology of the Districts of Worcester, Robertson, and Ashton (Cape Colony)." 2. Baron Ferencz Nopsca, Jun., "The Geology of Northern Albania."

Auctioneers, 34, Russell-square, W.C., 7.30 p.m. (Junior Meeting.) Mr. E. L. Pierce, "Land Banks and Agricultural Co-operation."

United Service Institution, Whitehall, S.W., 3 p.m. Mr. W. F. Reid, "The Use of Explosives in Aerial Warfare, with some remarks on Methods of Defence."

Literature, Royal Society of, 20, Hanover-square, W., 5 p.m. Dr. W. E. A. Axon, "Sources of Longfellow's 'Tales of a Wayside Inn.'"

Mining and Metallurgy, at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W., 8 p.m. 1. Mr. A. Beeby Thompson, "The Relationship of Structure and Petrology to the Occurrence of Petroleum." 2. Mr. A. L. Shrager, "Shaft Sinking against Water in Fissured Ground by Cement Injection."

THURSDAY, FEBRUARY 23...Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Child Study, 90, Buckingham Palace-road, S.W., 7.30 p.m. Discussion. "Should Games be Organized?"

Royal Institution, Albemarle-street, W., 3 p.m. Dr. P. Chalmers Mitchell, "Problems of Animals in Captivity." (Lecture III.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. F. H. Evans, "Pianism of the Pianola."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Discussion on Mr. W. T. Taylor's paper, "Long Distance Transmission of Electrical Energy," and Messrs. R. B. Matthews and C. T. Wilkinson's paper, "Extra High Pressure Transmission Lines."

FRIDAY, FEBRUARY 24...Royal Institution, Albemarle-street, W., 9 p.m. Professor Jean Perrin, "Mouvement Brownien et Realité Moléculaire."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. J. Swinburne, "The Uses of Chemistry in Engineering." (Lecture II.)

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7.30 p.m.

SATURDAY, FEBRUARY 25...Royal Institution, Albemarle-street, W., 3 p.m. Mr. T. G. Jackson, "Architecture: The Byzantine and Romanesque Period." (Lecture III.)

Journal of the Royal Society of Arts.

No. 3,040. VOL. LIX.

FRIDAY, FEBRUARY 24, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 27th, 8 p.m. (Cantor Lecture.) Professor ADRIAN J. BROWN, M.Sc., "Brewing and Modern Science." (Lecture IV.)

TUESDAY, FEBRUARY 28th, 4.30 p.m. (Colonial Section.) The Hon. Sir RICHARD SOLOMON, K.C.B., K.C.M.G., K.C.V.O., K.C., High Commissioner for the Union of South Africa, "The Resources and Problems of the Union of South Africa." The Right Hon. LEWIS HARCOURT, M.P., Secretary of State for the Colonies, will preside.

WEDNESDAY, MARCH 1st, 8 p.m. (Ordinary Meeting.) LEONARD ERSKINE HILL, M.B., F.R.S., "Caisson Sickness and Compressed Air."

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES ON "BREWING."

On Monday Evening, the 20th inst., Professor ADRIAN J. BROWN, M.Sc., delivered the third lecture of his course on "Brewing and Modern Science."

The lectures will be published in the *Journal* during the summer recess.

CANTOR LECTURES ON "PYROMETRY."

The Cantor Lectures on "Pyrometry," by Mr. Charles R. Darling, A.R.C.Sc.I., F.I.C., have been reprinted from the *Journal*, and the pamphlets (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John-street, Adelphi, London, W.C.

A full list of the Cantor Lectures which have been published separately, and are still on sale, can also be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A Meeting of the Indian Section was held on Thursday, February 9th, 1911, the Right Hon. Lord LAMINGTON, G.C.M.G., G.C.I.E., presiding.

The paper read was—

INDIAN SUPERSTITIONS.

By R. A. LESLIE MOORE, I.C.S. (retired).

PREFACE.

I should like to preface my paper on Indian Superstitions with two remarks. The first is that the paper does not pretend to be exhaustive, and the second that it is not written in any spirit of condescending superiority towards the domestic beliefs of a people whose civilisation is older than our own.

Such an attitude would ill become a citizen of the United Kingdom, where in England persons not devoid of education are averse from sitting down thirteen to dinner, where in Scotland the careful housewife hopes that the first foot set in her house on New Year's Day will be that of a dark man, so that the household may have good luck throughout the year, and where in Ireland no good old family can do without its banshee, that uncanny harbinger of woe which, *more Hibernico*, laments a death before it has occurred. I should like also to acknowledge my obligations to various friends, both Indian and Anglo-Indian, and last, but not least, to the Bombay Anthropological Society for information supplied.

OMENS.

To turn to the subject of the paper, let us begin with the Indian belief in omens. Among Hindus it is a good omen to catch sight of the following things:—(1) curds, (2) *ghi*, (3) rice, (4) milk, (5) flesh, (6) fruit—all it will be noticed, common articles of diet; (7) a looking-glass, (8) ornaments, (9) jewels, (10) newly-washed

clothes, (11) an umbrella—all of which may be termed articles of the toilette, except perhaps the umbrella; (12) a cow, (13) an elephant, (14) a dog wagging its tail—all three familiar quadrupeds to the Hindu, and not hard to see, especially the elephant; and finally some sundries, such as (15) precious metals, (16) weapons, (17) a sparrow, (18) a peacock, (19) a soldier, (20) a blot of ink.

The Hindu has then a fairly good chance of getting good omens, and if the same rules apply to Londoners we may all hope by good luck to catch sight of sparrows and tail-wagging dogs. On the other hand, it is an evil omen for a Hindu to see:—(1) a smoky fire, (2) medicine, (3) salt, (4) oil, (5) hay, (6) timber, (7) rain, (8) mud, (9) cats, (10) owls, (11) snakes, (12) a beggar, (13) a drunkard, (14) a bald man, (15) a grey-eyed man. Obviously a Hindu must be careful where he looks. But it seems hard on the grey-eyed and the bald to class them with drunkards. And as for Londoners they stand, I am afraid, a poor chance, what with rain, mud, beggars and cats.

But the worst omens of all are to stumble when starting on a journey and to drop a plate. It is pleasant, however, to know that a stray pigeon brings good luck to the house where it alights, that a cat cleaning its face with its paws predicts the arrival of relations, and that, contrary to the usual rule, good luck is brought to a house by a black cat with a white face. On the other hand, Hindus believe the omen bad if at the commencement of a journey the right eye of a woman or the left eye of a man throbs or winks.

Among Indian Mussulmans an unlucky omen at the commencement of a journey is to hear a donkey braying or a jackal yelling—neither of them uncommon sounds in India. But the cry of the black partridge, though scarcely melodious, is lucky, and it is lucky, too, to set out with the moon full in one's face. Good fortune may also be secured at the start by presenting someone with a pie; as three pies go to a farthing, the price of good luck does not seem excessive.

Among Parsis good omens are drawn by travellers setting out on a journey from the sight of:—

1. A woman with a full water-pot on her head.
2. A sweeper with a basket on his head.
3. A washerman carrying a bundle of clean clothes.
4. Flowers or fruit.
5. A snake on the right hand.
6. A pot of toddy.
7. And finally a corpse. The belief in the last good omen is shared by Hindus. It is also lucky for the traveller just after starting to look back when called, as that means he will return safe and sound. But bad omens are drawn if the traveller, on setting out, catches sight of:—

1. A woman with an empty water-pot.
2. A washerman with a bundle of dirty clothes.
3. A snake on the left hand.
4. A cat crossing the path.

It is lucky to hear a clock striking, a bell ringing, or a gun firing during the discussion of a business enterprise, as the omen drawn is that the enterprise will succeed; but it is most unlucky to hear on such an occasion a woman sneeze—apparently the moral is that women and business are best apart. I regret to conclude with a trio of bad omens, which consist in the breakage of a chandelier or globe, the breakage of a wife's glass bangles, and hearing at night the howling of a dog. As regards the bangles, the ill-luck is about to occur to the woman's husband; this belief is doubtless due to the fact that a woman on becoming a widow breaks or takes off her bangles.

Among Goanese Christians, it is a good omen to see:—

1. The mother of a large family.
2. A cow with a calf.
3. A marriage procession.
4. A sweeper.
5. A widow (if she is young and comely).

But it is a bad omen to see:—

1. An ordinary widow.
2. A faggot of wood.
3. A piece of coal.
4. A bare-headed man out of doors.

The Goanese also believe that a sick man is near to death if a dog howls, an owl hoots, or a crow caws in his vicinity. They think these creatures can scent the approach of death—a faculty shared by the Irish banshee. Probably in all three cases the bad omen is due to the melancholy nature of the sound.

The Hindus in Portuguese territory believe that if a cat mews at night she predicts the approaching death of a member of the family. It is thought that an ancestor has taken the shape of a cat to give his relatives warning. However, the omen may be averted by offering food to the spirit of the deceased, similar viands being consumed by the males of the family. The

ladies, however, must not partake, as they are ceremonially impure.

The Evil Eye.

Let us now consider the fascinating subject of the "evil eye." Belief in the evil eye is not, of course, confined to India. It is prevalent, for instance, in Italy. Many of us will remember Rudyard Kipling's gruesome story of the haunted bungalow, where the mangled corpse of the young assistant magistrate was found between the ceiling and the roof. The unfortunate youth's throat had been cut by his servant because the man believed the Sahib had cast the evil eye on his little son. According to Indian belief, good and comely persons and things are those most in danger of suffering from the evil eye—the basic idea perhaps being that good fortune breeds the pride that goes before a fall. The evil-eyed one is not necessarily a person of evil nature, and, most unfortunately, does not exhibit any outward and visible sign —such as a squint—by which he may be recognised and avoided. However, for the protection of the public, it is well to place on record that there are certain classes generally addicted to this deplorable characteristic, *e.g.*, witches, beggars, scavengers and Europeans—not a flattering collocation to the latter, but it is well sometimes "to see ourselves as ithers see us."

An attack of evil eye may be diagnosed by the symptoms of loss of appetite, vomiting, fever and sometimes delirium. As prevention is better than cure, the first essential is to ascertain how the evil eye may be averted. Well, a prime specific, especially in the case of children, is to rub some lamp-black on the forehead. More ornamental prophylactics are bears' hair, tigers' claws, and shell garlands. For the protection of trees a tasteful appendage of old shoes is highly effective, and animals are safeguarded by black threads fastened round their necks or horns. We have next to consider how the effects of the evil eye may be cured. A favourite remedy is to mix on a tile some dust from a spot where three cross-roads meet, with salt, chillies, and coriander seed, then to wave the tile round the head of the patient, and finally to put it in the fire. Hindus have also great faith in a thread tied round the arm of the patient over which a Brahman priest has repeated mantras, while Goanese Christians prefer to burn in the patient's presence a hair or thread obtained from the evil-eyed one without his knowledge or consent, somewhat on the principle of curing a bite by a hair of the dog that bit.

Spirits.

From the evil eye let us pass on to the topic of spirits, both disembodied spirits commonly called ghosts, and spirits who have never had a human body. The latter are in India divided, like their human contemporaries, into two chief classes — Mohammedans called Djinns, and Hindus called Bhuts. I am credibly informed that Djinns can easily be recognised by their inability to wink—whether owing to physical or moral rigidity I am unable to say. However, as a compensation they are provided with elastic arms and legs. Thus, a Djinn would think nothing of suddenly stretching out his arm and picking a sparrow off a housetop or extending his leg and crushing with his foot a black-beetle at ten or twenty paces distance. To turn to Bhuts, in my green and salad days in Poona I remember that the first chuprassie I ever had absented himself for a week at the time of Holi, a season of merrymaking, on the plea that he was suffering from shock—the shock of meeting a Bhut near a burning-ground on his way home. He recognised the Bhut by his eccentric method of walking with his heels in front and his toes behind. In fact his feet were reversed on his ankles. By this you may know the Bhut. Riding on another occasion into a Sindhi village, I found the village accountant's official residence, which stood on the outskirts of the village under a spreading banyan tree, deserted, and the man himself located in a hut in the main street. On inquiry I was informed that the banyan was haunted by a Bhut who objected to neighbours, and showed his objection by throwing stones at them.

My third experience of Bhuts occurred in Khandesh. Visiting an outlying village early one morning I was met by a deputation, who asked me to order the arrest of a Bhut. Thinking that even a Bhut should have fair play, I asked for details of the charge, and was told that the accused had the night before levanted with a baby. It appeared that the keeper of the local liquor shop had gone the previous day to a larger village to replenish his stock, leaving at home his mother, his young wife and infant. According to the wife, at dead of night a black, hairy Bhut came down the chimney, tore the baby from her arms, and again disappeared up the chimney. Full inquiry was made, but the infant was never recovered, nor was any reason for its removal disclosed. I am inclined to think that the Bhut was really a wolf which entered and departed through the door, and that the women were

afraid to confess this lest they should be blamed for failing to bar the entrance.

It is perhaps well to know that Bhuts may be exorcised by an offering of curds, for which they have a liking, more especially as low-class Bhuts are in the habit of causing nightmares by sitting on the victim's chest and trying to suffocate him. This class of Bhut is probably the offspring of indigestion.

To proceed from Bhuts in general to Bhuts in particular—*i.e.*, local species of the genus Bhut—it may be noted that in Bengal there is an unpleasant specimen called Nishi, who is accustomed to take her walks abroad in female human form after midnight. She calls people thrice by name, and if they come out of doors lures them into the jungle and destroys them. Hence, in Bengal, if you wish to get a friend out of doors after midnight, you must call four times.

One of the residents of the Madras Presidency is a superior sort of lady Bhut called Amman. Her *spécialité* is the infliction of small-pox and cholera, but she can be placated by the sacrifice of goats and cocks, and the performance of frantic dances by anyone who likes the exercise. She has no special priests, and her temples are always on the village outskirts. It may be noted that when the dancer becomes hysterical through his exertions he is questioned by the bystanders as to the cure of disease, the method of accomplishing wishes, the welfare of absent friends, and other interesting topics.

In connection with these Madrasi Bhuts, I remember reading that a certain touring member of Parliament once instanced in the House of Commons the fact that a deceased officer's manes were placated with offerings by the local Dravidians as a proof of the tyranny of British rule in Madras. As a matter of fact, the poor man had died in a lonely spot near the coast on his way to England, and the kindly villagers, rightly thinking that his ghost would feel lonely so far from home, were in the habit of offering it consolation in the appropriate form of spirits and cigars, a proceeding that did much credit to their good nature.

I may conclude my remarks on Bhuts by mentioning a Goanese species called Vento Ruim, who hovers over men, counteracting the influence of their good angels and impelling them to evil. Vento Ruim seems to be the local form of a Christian idea that each human being has an attendant guardian angel and malign spirit, the embodied forms of good and evil tendencies.

We will next deal with disembodied spirits, commonly called ghosts. An eminent medical officer told me of a haunted bungalow inDharwar, said to be the local habitation of a deceased ayah. This obtrusive female had the habit of appearing to ladies shortly after childbirth, who never survived the shock of her appearance. He told me of two such deaths in this bungalow, for which he was unable medically to account.

Then I was told by an acquaintance that he had himself seen in a Sindh district bungalow the ghost of a servant who was said to have committed suicide there. The spectre was in the habit of appearing to visitors, and pointing to its throat, which was cut from ear to ear. My acquaintance, however, was notoriously subject to fits of nightmare and imagination.

In a third case an assistant collector, whom I knew, managed, with the aid of a thick stick, to exorcise an uneasy sprite which had a taste for mangoes, especially those growing in my friend's compound. In this case the reputed ghost was found to occupy for the time being the earthly tabernacle of a neighbouring fakir.

But to turn from the particular to the general. There is a belief that the spirit of a deceased person will sometimes pay off old scores by haunting an enemy. This reprehensible practice is most common amongst deceased daughters-in-law, and, in order to prevent its occurrence, mothers-in-law who are conscious of having been overstrict will sow mustard-seed between the family mansion and the burning ghaut. The ghost, on its return journey, lingers to pluck the mustard flowers, and so is overtaken by the dawn, when it has to return whence it came.

Another belief among Hindus is that for ten days after death the spirit of the deceased lingers in the house. An oil lamp is, therefore, kept burning, round which the ghost hovers like a moth, transmigrating, at the end of the ten days, into another body.

In Goa it sometimes happens that stones are thrown by unseen hands on the roofs of houses occupied by native Christians. This affront must not be credited to mischievous Bhuts or boys. No! The stone-throwers are the souls of the departed faithful, who find that their exit from purgatory has been delayed by an insufficient expenditure on masses and alms on the part of their surviving friends. When the deficiency is made good, the stone-throwing ceases.

To conclude with a warning. Do not go after dark near a well or pond in which anyone has been drowned, as the ghost of the deceased haunts the place and may injure you—at least, so Hindus believe. They think that women are

sometimes obsessed by such spirits. However, it is well to know that shouting "Ràm, Ràm!" will drive away ghosts, and this precaution should be observed, especially on Tuesdays and Saturdays, when spectres have their evenings out. Perhaps I may add one remark—not about ghosts exactly but about what Madame Blavatsky and her friends called "astral projections." Sometimes, when a man is asleep, his astral projection goes out for an airing and occasionally gets thirsty. Then it repairs to an uncovered water-jar, and if the cover is put on suddenly the A.P. is shut in, to the inconvenience of its sleeping owner.

Marriage.

Perhaps something cheerful would be desirable after so gloomy a subject as ghosts. Let us, then, briefly consider ideas about marriage. Bachelors and spinsters should please take note.

Anyone killing a frog will never get married. On the other hand, according to a picturesque Bengali fancy, if a butterfly enters and flits about a house there will soon be a marriage in the family; and if the butterfly persists in hovering about any particular person, that person is destined for early connubial bliss. The following Hindu receipt for securing husbands will be of interest:—Let the aspiring spinster buy curds at a shop that is about to close for the day, or let her look upon a bridegroom at a marriage ceremony, and then, turning her back upon him, go straight home. The result will be all that can be desired.

Perhaps one or two items from the marriage customs of other Indian people will be acceptable. A Parsi bride, when being adorned for the marriage ceremony, always stands with her face to the East, as the East is the lucky quarter because the sun rises there. Among the Mussulmans of Sindh the bride is seated on an overturned basket under which a hen and a brood of chickens have been placed. Then she rises and lifts up the basket, letting the chickens out. The number of chickens she can catch is the number of her future progeny. After this display of agility, she has to engage in a feat of strength by holding a date grasped in her fist. If the bridegroom with one hand can deprive her of the date he will rule in the married life to come, but if he fails he may expect, as the Scotch say, to be "Sair hadden doon." When the bride goes to the bridegroom's house for the first time her mother-in-law takes care to secure good luck for the marriage by having the posts of the house-door smeared with the blood of a goat slain for the purpose, and by swinging a black hen thrice round the bride's head just before she enters the house.

Magic.

We must now be sufficiently braced up to tamper with the awesome subject of magic—*i.e.*, witches and wizards, charms, spells and prophecies. I have a very clear recollection of one victim of witchcraft, whose acquaintance I made when inspecting the jail in the Guzerat State of Dharampur. The Raja, who was opposed to capital punishment, had sentenced him to imprisonment for life because he had killed his mother-in-law. The prisoner—he was a Bhil—explained to me that he had quarrelled with his mother-in-law, who was a witch, and she in revenge had bewitched his little boy, his only son, so that the child fell sick and died. The father's repartee took the form of cracking the old woman's skull with a wood-chopper.

Indian wizards bring disease, and even death, on their enemies by making effigies of them, which they maltreat much as did the European sorcerers of the Middle Ages. The Hindu wizard shoots arrows into his effigy from a bow made of a bamboo, which has been used to fasten down a corpse during its cremation.

The Mohammedan practitioner, on the other hand, makes his effigy out of grave mould and transfixes it with pegs to the accompaniment of passages from the Koran recited backwards. The effigy is then buried in a graveyard in the sure and certain hope of the speedy death of the original. Apparently, in these cases the effigy represents the "other self" of the victim, the idea of a double self being common to many races.

The above may be called black magic. However, white or beneficial magic is also well known in India. Hindus frequently call in sorcerers to deal with cases of hysteria, which they ascribe to demoniacal possession. The sorcerer's *modus operandi* is briefly as follows. He begins by demanding presents for himself and the demon. Then he recites incantations, at the same time passing his hands over the patient and rubbing him with a mixture of oil and dust or water and dust. If this does not suffice he belabours the patient with a slipper or a broom, frequently with satisfactory results. It is claimed that other diseases besides hysteria can be cured by incantations and external applications, but another method is to transfer the diseases from the patient to someone else. This the sorcerer accomplishes by drawing cross-lines on a road, at the same time repeating incantations. The first person who walks over the lines relieves

the patient by taking his diseases upon himself. Such a belief must add a new horror to life. Another less callous method of transferring an ailment—in this case consumption—prescribes that the patient should swallow a piece of paper inscribed with a magic formula, written in Sanskrit for Hindus and extracted from the Koran for Mohammedans, and should then undress and bathe in the midst of a crop of sugar cane. The consumption will leave the patient and attack the crop in the form of blight.

Goanese Christians believe that their local sorcerers can foretell the future when frenzied by dancing wildly like the Madras devil-dancers. Sorcerers are also very useful in detecting witches. This they do either by throwing salt on the suspect, which benumbs her if she is guilty, or by requesting her to step over a ladder, which she cannot do if really a witch.

These methods are much more humane than those in vogue in England in the days of King James the First, when it was customary to throw the suspect into a deep pond. If she sank to the bottom and stopped there she was innocent—much to the consolation of her surviving friends; but if she floated she was a witch, and was promptly taken out to be hanged or burnt.

Something may now be said about charms and spells. Parsi cultivators protect their crops from vermin by placing in their fields charms written down by a priest after prayer and ablution. Hindu cultivators achieve the same end by putting amid their crops a magic square, of which the numbers total up to thirty-two whether added perpendicularly or horizontally. I understand that in Burma, Was protect their crops by placing among them human heads cut off for the purpose, the idea being that the spirits of the deceased will warn off other sprites. With this may be compared the Indian idea that the spirit of his first victim sits on the head of a man-eating tiger and directs him where to go.

Goanese Christians have a choice collection of charms for removing the evils caused by witchcraft. The chief of these are:—

1. Earth from saints' graves.
2. Relics of saints.
3. Written prayers addressed to saints.
4. Images of saints.

They also have a picturesque belief that oars, sails and bells sprinkled with holy water are safeguarded against thunderbolts.

Some details of the Mohammedan belief in the miraculous powers of Syuds, dead and alive, may not be out of place. The spirit of a dead Syud is supposed at times to obsess living persons, and make the announcement in the Syud's name that offerings should be made at his grave. I remember myself an instance that occurred over twenty years ago at Ahmedabad, when a deceased Syud resented the decrease in the offerings at his shrine by growing in his grave (so the caretaker of the shrine informed the public). This underground growth necessitated the lengthening of his tomb above ground, and such was the elongation of the holy man that a public path was in danger of being blocked. At last the district magistrate had to address an injunction to the caretaker of the tomb, after which the deceased grew no more.

On another occasion, when I was arranging a campaign against locusts in the Rohri district of Sindh, which borders on the Jaisulmir desert, an ancient zemindar told me we ought to have the aid of the Syud Hazrat Shah. I expressed myself pleased at the prospect of the Syud's co-operation, but was informed that the worthy divine had sought the arms of the Houris long years before. However, it appeared that his practice had been to catch one of a swarm of locusts and ride off with it into the desert, whither the swarm followed him not to return. I may, in conclusion, mention a story current in the town of Rohri that some fifty years ago a certain holy Syud had raised from the dead the Bunnia who used to lend him money because the trader had left no son behind him to transact the Syud's business. The Bunnia, who had been recalled to life while being carried to the burning-ground returned home and obligingly begat a son. As soon as the latter had reached years of discretion, the father was allowed to shuffle off the mortal coil in peace. This tale was told me as strictly true by an educated Hindu of the Amil caste, who said his father had known all the parties in the case.

The shrines of deceased Syuds are favourite places for pilgrimage and votive offerings. Near Rohri is the shrine of the famous Saki Sarvar (Nur Jo Parwar, protector of light, as he is popularly called). His *spécialité* is the cure of sore eyes. Hard by Ahmedabad is the shrine of the equally renowned Shah Alum. Often have I seen the railings round his tomb adorned with little locks of infants' hair, presented by happy mothers to whom the deceased saint had vouchsafed a son in answer to their prayers.

In this respect India and the Emerald Isle are close akin. In the year 1909 I saw in

County Louth a holy well overhung by a tree, the branches of which had been festooned with rags by pilgrims. To the best of my recollection St. Bridget was the patron saint of the locality.

Now, it is easy to smile at such simple practices, but faith works wonders, as an instance of which let me quote an experience of my own. I had on one occasion to deal with a severe outbreak of cholera in East Khandesh. One village remained unscathed in a circle of others that were affected. On visiting this village I found it surrounded by a line of cotton yarn tied from tree to tree, and the Patel informed me that the villagers had taken the precaution at the outbreak of cholera in the neighbourhood of publicly expelling a Mang woman from the village bounds with beat of drum, after which they encircled the village with cotton yarn. In consequence cholera did not enter their precincts.

Perhaps before leaving the subject of magic I may mention the Mohammedan custom of foretelling the future by consulting the King of the Djinns—called Hazirat. This is done by the operator hypnotising a young boy, after placing in his hand a betel-leaf smeared with lamp-black. The medium, looking on the lamp-black, answers the operator's questions by telling him that he sees the King of the Djinns appear as in a mirror. The King, on being questioned, answers the questions put to him through the medium.

Hindus foretell the future both by astrology and palmistry. I remember that a Hindu astrologer foretold a devastating earthquake in the spring of 1898, when I was at Surat. I happened to go out after black buck very early on the morning when the earthquake was due, and found the population of whole villages sleeping with their cattle in the fields—old men and children, young men and maidens. They told me they thought their chances of escape from the earthquake were somewhat better in the open. Well they did escape, for the earthquake never came off. On my chaffing a Hindu friend about this, he replied indignantly that the astrologer had been quite right—only the earthquake had happened in Persia. I have heard of a Madras astrologer who acquired a competence by predicting the issue of cases tried by the local High Court. An instance in which a palmist successfully foretold the future occurred to my knowledge in the case of a lady who had lately settled down in a house near Bombay, shortly after arriving from England. A Hindu palmist informed her that she would presently give up the house and revisit Europe. She laughed at his apparent bad shot, as she had only just returned from home, and her husband had taken their house on a three years' agreement. Yet in a month or two news of the illness of a relative recalled her to England, and shortly after her arrival in London she received a letter from her husband, telling her that there was a flaw in the agreement, of which the landlord had taken advantage to cancel his tenancy.

Animals, Birds, Reptiles, Insects, and Trees.

We may now pass from supernatural things to things natural, so far at least as they can be considered natural when viewed with the eye of superstition. I propose to treat of beasts, birds, reptiles, insects and trees.

Anyone who has ever shot a tiger will remember the precautions necessary to prevent the beaters from clipping the deceased's whiskers. The jungle tribes believe that a diet of clipped tigers' whiskers will endow them with the courage and vigour of the jungle king, though, *prima facie*, the probable result would be indigestion. The terror inspired by a man-eating tiger is naturally increased by the belief that the ghost of his first victim sits on his head and directs him where to go and what to avoid. Can any good come out of a panther? Certainly. Panther's fat is good for rheumatism, and the milk of a she-panther is a sovereign remedy for sore eyes. My authority for the former statement is the excellent Raja of Dharampur, whose jail I have already mentioned. I supplied him with panther's fat at his own request, as advancing years were affecting his honourable bones with the aches that human flesh is heir to. I have myself seen beaters squeezing the milk from the dugs of a she-panther just shot by me, and catching it on leaves in order, as they informed me, to keep it as an eye lotion. A bear is notoriously an awkward customer to meet face to face on a jungle path. However, a shout will generally make him retreat. But shout before he growls because, in growling, he straightway becomes deaf. Hence the Mahratta proverb, "Aswalitsya adhi kink phodavi"—shout before the bear growls. This saying is applied to quarrels, and suggests that the man who speaks first is generally believed—in other words, it is hard to overtake a lie.

Indians will often choose a horse, not for the feminine reason that he has a nice tail, but because of certain lucky curls in his hair. In Madras, Hindus have a poetic fancy that the

callosities on a horse's legs show the places where wings once grew.

In olden days men warred against the gods, and tried to fly to heaven on winged steeds. The gods then took the precaution of clipping the horses' wings. Can it be that this myth is a reminiscence of prehistoric aeroplanes? Do not walk over the place where a donkey has lately rolled if you wish to avoid pains in your feet. Donkeys are not favourites in India. Their nostrils are slit in a vain attempt to soften the harshness of their bray. Naturally enough the donkey is supposed to bray because he catches sight of the devil. He is looked upon as unlucky because he is the steed of Sitala, goddess of small-pox. This lady's favourite offering is a pig, which should be let loose in her honour by those who recover from small-pox, lest they suffer again.

Hindu shrines are often built where milch-goats have let down their milk, which they are reported to do when they have discovered a holy place. Orthodox Hindus may (and do) hit cows with sticks, but consider it improper to kick them. When they break bread they keep the first piece for a cow, the second for a dog, and the third for a crow. During epidemics an attempt is often made to free a village of the disease by garlanding a buffalo, putting a red caste-mark on his forehead, and driving him out of the village. Hindus believe that the stripes on the Indian squirrel are the marks of the Monkey King Hanuman's thumb when he seized it to fill up the last gap in the bridge he built between India and Ceylon. This brings us naturally to the joyous monkey. This fascinating creature is the centre of various Hindu beliefs. Thus, he does not speak for fear he should be made to work. He is often kept in a stable to avert ill-luck from the horses, because, like the quail, he is an ill-luck conductor. You are in luck if you see him before breakfast, but you must not speak of him.

Finally, it may interest the audience to know, that in Hindu opinion the English are descended from Hanuman, the Monkey King. After all, Hanuman was a good fighter, and apparently a cheery soul, to judge from the red-leaded images of him adorning every Deccan village.

Indian Mohammedans have their own beliefs about animals. For instance, they recognise the thumb-mark of their great Prophet on the neck of every well-bred Arab horse. They give an historical reason for the camel's hump by saying that it represents the mountain into which the Angel Gabriel conveyed the body of Moses laid on the camel's back—humpless before that day.

Mohammedans have a poor opinion of dogs. A vessel from which a dog has drunk must be washed seven times to cleanse it. Angels will not enter a house where there is a dog. (Here it may be noted that Hindus believe that dogs can see spirits.) Mohammedans, again, have a quaint cure for hydrophobia. This consists in looking down seven wells. Finally, they assign places in Paradise to certain mammals, of which the following are the chief:—

1. Moses' camel.
2. Abraham's ram.
3. Solomon's ant (praised for industry).
4. The Queen of Sheba's parrot (renowned for eloquence).
5. Jonah's whale.
6. And last, but not least, the golden calf worshipped by the erring children of Israel.

To turn again to Hindu beliefs. The owl in the East as in the West is a foreboder of evil to come. But mark this: It is worse than useless to throw stones at it. For it picks up the stone and gradually rubs it down to powder. As the stone wears away so the thrower falls into a decline, and finally becomes dust to dust at the same time as his missile. The Indian crow is, of course, a ruffian of the deepest dye, and yet he has his uses. Pious Hindus annually offer rice balls to the spirits of their departed ancestors and these must be consumed by the crows to show that the offering has been accepted. It is this belief that put a stop to a crusade for the extermination of crows in Bombay City not many years ago.

A parrot is a lucky bird to have in a house, perhaps because he is the steed of Kama, the Indian Cupid. Indian mothers will divide almonds between parrots and their small children in order that the latter may acquire the parrot's fluency of speech. A quail is also a lucky pet, but for a different reason; he attracts misfortune to himself—is, in fact, a sort of bad-luck conductor. If a koil, or brain-fever bird, persists in emitting his excruciating song near your house you may expect the arrival of a relative. But if a pigeon builds in your roof ill luck will come and your house will become deserted. However, if on a business journey you meet a kite with a white bill you may hope for success. If a spider falls on you, you will soon get new clothes, but the touch of a lizard pollutes you. In Burma, however, the image of a lizard is considered a talisman against danger. Should you kill a snake burn his corpse, because he is

by caste a Brahmin. Snakes are considered the guardians of the village cattle. The cobra carries a precious jewel in his head which is an antidote to poison, and brings good luck, but it is hard to secure. The bis-cobra is supposed to be endowed with legs and a sting in its tail.

I remember once being roused by a hurly-burly in my verandah at Jacobabad, and on going out to inquire was shown with pride a bis-cobra which my chuprassies had jointly succeeded in belabouring to death. They told me if it stung anyone the victim must run to the nearest water for which also the bis-cobra would make. Whoever lost the race would die. The reputed bis-cobra, however, turned out to be a thick-tailed stingless lizard. The graceful pipal tree (*Ficus religiosa*), whose slender pointed leaves quiver in every passing breath of air, attracts to itself varying superstitions. Thus Buddhists believe that its nerves were upset by the tremendous scenes it witnessed when Gautama Buddha sat in its shade and endured temptation at Buddh-Gaya when the world was young. Hindus, on the other hand, imagine that the rustling of its leaves is caused by the whispering of spirits who sit aloft among its branches, the spirits of little Brahmin boys who died before they donned the sacred thread. Hence one should never tell secrets under a pipal tree for the spirits will overhear and repeat them. The banyan (*Ficus indica*) and the neem (*Melia azadirachta*) are favourite haunts of Bhuts, and should be avoided by ladies.

Miscellaneous Superstitions.

Perhaps I may be allowed a few remarks about miscellaneous superstitions. It is a common belief that the foundations of large masonry works cannot be well and truly laid without a human sacrifice, preferably the insertion of a human head, amid the building materials. There was a belief during the early days of the plague in Western India, also turning on human sacrifice, of which I had personal experience. It was thought that an ointment of human brains was required by Government to remove the stains from Queen Victoria's statue in Bombay, which some ruffians had defiled at night. Hence much of the reluctance to go to the plague hospitals, where the Doctor Sahib lay in wait to poison patients and extract their brains. Hence, too, the falling off in the attendance at schools in the backwoods of Surat, as I found on tour.

In days of yore Goanese fishermen used to propitiate the sea at the beginning of the fishing season by offering up human victims, but in these less hardy times they rest content with cocks. On the day of Nareh Pornima, Hindus throw coco-nuts into the sea as an offering to the marine deities, and Brahmins bind amulets round fishermen's arms to protect them against the perils of the deep. Two more Goanese beliefs may be mentioned. One is that if a crime has been committed and a number of persons are under suspicion, they should in turn place their hands on an iron pot in which a cock has been placed. The cock will crow when the guilty man puts his hand on the pot. Another is that the corpse of a murdered man will bleed if the murderer draws nigh. The same belief prevailed in Scotland, as narrated by Sir Walter Scott in "The Fair Maid of Perth."

To turn to less gruesome beliefs, Hindus think that to have a lucky day one should begin by looking on a lucky face, so they look at themselves in a mirror. They have a specific against seeing ghosts, which consists in sleeping with an almanac under one's pillow. Then they have their own ideas about hygiene just as some of us have. Thus they think that drinking water immediately after eating bananas causes goitre. And eating ducks' eggs causes rheumatism. Moreover, it is unlucky to eat any sort of egg when starting on a journey. Housewives will be glad to know that cockroaches improve the sanitation of a house. If a Hindu husband dreams of a snake he is about to become a father. When the baby arrives in due course, the day after its birth pen and ink are kept near it so that Chitragupta, the God of Fortune, who will shortly pay a call, may have facilities for writing its fate on the child's forehead. Hindus have what may be called compensatory beliefs about drowning. Thus they think that anyone whose hair curls in a certain way is born to be drowned, but, on the other hand, that anyone who accidentally eats ants in sugar will escape drowning. So there is hope even for the curly-headed. But neither they nor any other man should venture into a boat with a single woman. However, it is fair to add that the femme-sole is equally dangerous to one man or many. A Hindu thinks that three is an unlucky number, so never gives three presents to a friend. He also believes that if he bites his tongue when eating he is being abused by someone. With this compare the European idea about ear tingling. Shakespeare remarks that, "Debt doth often lose itself and friend." Well, the incautious lender has some warning among Hindus, for he can tell by the

number of moles on the debtor the number of debts the latter contracted in a previous state of existence. Hindus think it kindly to snap their fingers if anyone yawns in their presence, to prevent stray devils skipping down the yawner's throat, just as they draw patterns before their doors at Divali to keep demons rom entering their houses. Again, they deem unlucky for a man to shave on his birthday. Similarly, an Irishman who shaves on Sunday runs the risk of toothache. Parsis, too, have their prejudices for they are averse from cutting their nails indoors, less they should thereby incur misfortune.

This portion of the paper may be fittingly closed by a reference to Hindu ideas about celestial bodies and natural phenomena. The planet Mars has a disturbing influence on the earth, which tends to produce wars and other political disturbances. This tendency is at present intensified by the existing conjunction between Mars, Saturn, and Jupiter, to which is attributed also the spread of plague. The approach of Halley's Comet was thought to indicate impending famine and pestilence, and also, so a Hindu friend has lately informed me, danger to the House of Lords. A Sadu lately appeared before a Calcutta police-magistrate asking that the dispenser of justice would order him to be sacrificed to the Goddess Kali so that the evil influence of the comet might be averted from the Government and people of India. Sad to say, his public-spirited offer was declined. Saturn has an evil disposition, and will blight the prosperity of anyone who falls under its evil eye for seven years unless in the meantime he induces a Brahmin priest to interfere. This, of course, costs money. Venus, the universal mischief-maker, is also an unlucky star, and the day of the week named after her, Shukrwar, Friday, is an unlucky day. Eclipses of the sun are due to the fact that the radiant orb is from time to time so shocked at human enormities that he hangs his head in sheer despondency. But eclipses of the moon occur because her ladyship is being dunned for debt by two supernatural ogres named Rahu and Ketu. To hasten payment they threaten to swallow her, and to obviate her extinction the pious offer up prayers and propitiate Mangs with presents, because Rahu and Ketu are of the Mang caste. After the eclipse is over, devout Hindus bathe and break their earthen pots as after a funeral. Comets and shooting stars portend the birth and death of princes. The rainbow is the bow of Indra shooting forth arrows of welcome rain over the thirsty land. Volcanic eruptions indicate the wrath of the God Shiva, the destroyer. Finally, earthquakes occur because the great cobra, on which the earth rests, moves his head to manifest the displeasure of his lord Vishnu, the preserver, at the misdeeds of men.

SUPERSTITIONS COMMON TO INDIA AND EUROPE.

And now I reach the last stage of our progress —that of discussing the superstitions common to India and Europe. Take the custom of blessing a man when he sneezes. Indians say "Live long!" Germans, "*Gesundheit*" (good health to you), and Frenchmen, "*À vos souhaits*" (I wish you well). This custom is said to be due to the fact that the first symptom of the Black Death of the Middle Ages was a fit of sneezing. Could that destroying epidemic have been a virulent form of the modern "'flu"?

Both Indians and Europeans draw omens from birds. Thus in France, if a stray bird enters a house the omen is good, and so in India the arrival of a stray pigeon brings luck. In both East and West the owl's hoot and the dog's howl are sounds of ill-omen. Italy shares with India a belief in the evil eye, and the same belief underlies the English practice of throwing an old shoe after a newly-wedded couple. Again, in India a horseshoe is a safeguard against evil spirits, while in England to find an old horse-shoe brings good luck. On the other hand, it is very unlucky to break a mirror whether in Europe or India. This belief is said to be due to the idea that injury is thereby caused to the "other self" appearing in the glass. Various Indian jungle tribes believe that witches can transform themselves into animals, and the same belief used to prevail in Yorkshire and Devon. But the Indian witch prefers the splendid similitude of a tiger, while her British compeer was content with the humble form of hare or cat. In France the witch was supposed to assume the dreadful shape of the child-devouring were-wolf. Finally, comets are believed both in Asia and Europe to portend the death of royalty.

Shakespeare himself wrote the lines—

> "When beggars die there are no comets seen.
> The heavens themselves blaze forth the death of princes."

Thus the minds of men, especially untutored men, Eastern or Western, in many ways evince their common origin when moved by deep-rooted

instincts and emotions. In the words of the prince of poets—

"One touch of Nature makes the whole world kin."

[P.S.—Mr. Gupta, in the course of the discussion that followed the reading of this paper, stated that he had never heard in Bengal of the superstition that Europeans had the evil eye or the belief that the English were descended from Hanuman, the Monkey King. I hesitated to dispute his authority myself, but I may say that after the proceedings had terminated a highly intelligent Bengali gentleman of my acquaintance informed me that he had heard of both these ideas in Bengal, and that they were prevalent among both Hindus and Mohammedans of that province.]

DISCUSSION.

The CHAIRMAN (Lord Lamington), in opening the discussion, said the Society was very much indebted to the author for his valuable compilation of the various superstitions prevalent in India. It did not do for people in this country to laugh or mock at other people's superstitions, because he believed that in the very latest of the Atlantic greyhounds there was no stateroom numbered 13, owing to the dislike of travellers to occupy berths designated by that particular number. The author had stated that the people of India who were supposed to possess the evil eye, and who were something in the nature of witches, were not to be judged by outward appearance. That was contrary to the feeling that used to exist in Europe, because all witches were supposed to be ugly, hideous, and, generally, hags; but Indian beliefs were rather more practical. Personally, he fancied more harm had been done in Europe by the good-looking witch than by any old hag that ever existed. The author had mentioned certain people whose spirit, when they went to sleep, was supposed to go out of the body and very often liked to go to a water-jar to get refreshment. Having travelled in New Guinea, he could remember when one of the party went to sleep in a boat, and for some reason it was required to wake him, none of the boat's crew would venture to do so, because it was supposed that when a person was asleep the spirit left the body, and if the body was disturbed the possessor of that body would invariably die. The author had referred in the course of his paper to the superstition prevalent in some parts of India, that the foundations of large masonry works could not be well and truly laid without a human sacrifice. He had an example of that superstition when he had the honour of being Governor of Bombay. It was the occasion of the visit of the then Prince and Princess of Wales to India, and their Royal Highnesses were to lay the foundation-stone of the great new docks which were to be built. He suggested that there should be a gathering of children to commemorate the occasion, but his idea was overborne by the criticism that if any child happened to get lost, which might easily occur in such a large gathering, it would be said that that child had been taken to be imbedded in the masonry work of the great docks. The author had referred to the question of earthquakes, and had stated that a prophecy made by someone of an earthquake taking place proved to be false. He remembered two years ago meeting a lady, whose veracity he had no reason to doubt, who stated she was so sensitive to changes in the atmosphere that she could always foretell an earthquake two or three days before it occurred. For instance, she was aware that the great earthquake in Messina would take place two or three days before it actually occurred, and when the occurrence took place she again had peculiar sensations or effect upon her body which the shock or changes in the weather always brought about. There might, therefore, be something more in the statement of the prophet than Mr. Moore was disposed to credit him with. Superstition, from his point of view, was a very material form of religion. A few years ago a book called "Myths" was published, which dealt with superstitions amongst the Australian aborigines, and the purpose of the book was to show that belief in superstitions in default of any real religion was of very great value indeed, that superstitions tended to give a certain stability and a certain idea of morals amongst the people, and were not to be lightly condemned. It was naturally a very material belief—a belief that by something happening to the body, or some occurrence, or some manifestation to the senses, either evil would come or good would be brought about. True religion was the exact converse of that. True religion said that what was apparently material was immaterial, that the soul and the unseen were the matters of vital concern to all. At the same time, superstitions did no doubt inculcate a certain principle in people, although when they were carried to extremes they were distinctly hurtful—as, for instance, the custom of human sacrifice. With regard to the question of the credibility of superstitions, he did not suppose anyone present really believed in them, but yet it was an extraordinary thing that, though people did not believe in them, the thing connected with the superstition very often did happen. Lockhart, in his "Life of Scott," mentioned how Mungo Park, when bidding farewell to some of his friends in this country for the last time, felt sure that he would never return, and surely enough he perished in Africa. There might be something in the proverb quoted in that book, "Freits attend those who heed them." Belief in material superstitions seemed to be quite contrary to the highest idea of Indian religion.

Sir GEORGE BIRDWOOD said:—As for criticism of Mr. Leslie Moore's delightful paper, he had nothing but praise to dispense. Mr. Leslie Moore had brought before them an immense mass of rare and refractory, indeed, almost intractable knowledge, gathered "from a far country," for the

greater part at first-hand by himself, and had presented it to them in the simplest and clearest language, as if he had copied it all out from private letters, written by him in India to friends in England: and had read his paper with an ease and force of enunciation quite exceptional among those who usually dealt in public with such impracticable themes, thus adding greatly to the gratification of his distinguished audience that afternoon. Mr. Leslie Moore might indeed rest assured that the volume of the *Journal of the Royal Society of Arts* containing his most praiseworthy paper would always remain a *locus classicus* on its seductive, if limitless subject.

For the rest, his own remarks would be directed primarily to the enforcement of the fact that Indian superstitions were not such a trackless wilderness of random beliefs, rites, customs, fairy tales, and often inexplicable "survivals," as were the corresponding and, in origin, identical superstitions of Europe, wherever the evolution of the spiritual life of the people had been disturbed and checked by religious revolutions; but consisted of a body of systematised, and, for the most part, even after 3,000 years, readily explainable, and, indeed, quite rational traditions and regulations, the binding authority of which is still unshaken in India—India of the Hindus—and, consequently, still plenipotent to quicken the vitality, and assure the stability of a unique, and as he (Sir George Birdwood) trusted, ever irresolvable idiosyncratic civilisation, based on an hieratic social economy of the highest ethical elevation and beauty in its ideals, and in its realities of boundless beneficence and grace—the grace that begets grace [Χάρις χάριν τίκτει].

"Superstitions," albeit limited by the qualification "Indian," was, as Mr. Leslie Moore acknowledged in opening his paper, too comprehensive a title for it; for superstition is the natural attitude, in fear, and awe, and reverence, and adoration, of finite man, before, to him, through his five senses alone, the unknown and unknowable Infinite; and includes all religions,* their dogmas, rituals, rules of conduct, etc.; all, from the most debased to the most exalted, being, in their time and place, equally reasonable and well-founded, and rightworthy, and obligatory; and essentially one and the same religion,—and of one and the same man; in accordance with the natural law of absolute unity in, and throughout exhaustless and incalculable diversity. Even in restricting himself to "Indian Superstitions," Mr. Leslie Moore had not attempted to enlarge on any but the most ubiquitous, and conspicuous, and popular of them, such as Omens, the Evil Eye, Spirits, Marriage Usages, and Magic. He (Sir George Birdwood) would confine his observations entirely to omens, and in the narrowest, practical application of the word omen; difficult as it is to discriminate, theoretically, between omens, and divination, vaticination, and prophecy.

* Cicero, Nat. Deor. xlii., defines superstition as, "a vain fear of the gods," and religion, "a pious adoration of them." But fear has been our schoolmaster to bring us, step by step, to the adoration, and the love of the Creator; in its perfected form, the love of all fellow-creatures, even of the brute creation: and that is Buddhism—and Buddhaized Hinduism!

The etymology of the word omen is now regarded as uncertain, and indeed, undeterminable; and although himself convinced that it sprang from a root in common with the Greek ὄρνις, "a bird," and "an omen," and again οἰωνός, "a solitary [flying] bird," such as the eagle and vulture, and "an omen," and that it therefore referred originally to omens derived from the observation of birds, he would nevertheless use the word, in the present connection, only in its now largely-extended meaning, as generically including every recognised species of omen for the disclosure of future fates of good and evil,* viz.: (1) Auspices, or presages [*cf.* sagacious], portents, ostents, *monstra* † or "warnings," etc., from the "inspection" of the flight and feeding of "birds." (2) Aruspices, i.e., Haruspices, or foresights, forebodings, etc., from the "inspection" of the "entrails" [*hira*, "empty gut," *cf.* Sanskrit, *hira*, "intestines"] of "birds" [and other "victims," *haruga*, from *harviga*, or *arviga*, meaning *hostis*] sacrificed for the purpose. (3) Auguries [*avis*, "a bird," and *garrire*, to chatter, etc., compare "gargle," Night-Jar, and Jay], or prodigies, wonders, foretold by the chatter, cry, and song notes, and singing of birds, etc. And (4) Oracles, or pre-"dictions," announced, usually in response to inquiries, by the gods; including the forecasting of future events by the drawing of lots [*sors, sortis*], turning to passages in books opened off-hand ["Sortes Homericae,"

* As to the original meanings — which I have above attempted clearly to bring out—of these œonological words, one etymology of "omen" goes back to the hypothetical Aryan root *av*; found in the Sanskrit *avi*, "observing," and *avas*, "favouring"; the Greek οὖς, and αὖς, "the ear" [also αἰσθητικός, "sensitive"]; the Latin *Ave*, "Hail!" *avus*, a "grandfather," *auris*, "the ear," *osmen* or *omen*, for *aus-men*, "a thing heard"; and the English [Norman] "Oyez!" audacious, and scout, words all referring to listening, and [Boer] "Oom," or Old-Man, in a reverential sense, as in "Oom Paul." On the other hand, the passages in Varro are quoted:—"*omen velut oremen*," and "*quod ex ore primum elatum est osmen dictum*." Hence Skeat says, some connect it with *os*, "the mouth," others with *auris*, "the ear." The words "auspices" and "auguries" are referred to the hypothetical Aryan roots *va* and *vi*, appearing in the Sanskrit *vaga*, "wind," Vayu, "Wind God," *vara*, "tail"—for fanning, as the yak's, and peacock's, and *vigh*, "bird"; the Greek οἰωνός [which I take to be cognate with "omen"]; the Latin *vagabundus*, "a vagabond," *vage*, "sparsely," "vaguely," "far and wide," *ventus*, "wind," *vannus*, "a winnowing fan," *avis*, "a bird," *auspicium*, divination from the flight of birds, and *augurium*, from the sound of birds; [and the English wind, winnow, winter, wither]. "Oracle" goes back to the Latin *os, oris*, "the mouth," as possibly, as will have been seen above, does "omen," from which we get the Latin *orare*, to pray, *adorare*, to pray to, and *orator*, "an eloquent speaker." In any œonological association, there is no word derived from the Greek ὄρνις; but its root is considered to appear in the Latin *ulmus*, "the elm," *alnus*, "the alder," and *ornus*, "the mountain ash," and the English [Scotch] "rowan-tree," or said "mountain ash," and in "ornithology."

† Cicero, Divin. xlii., says,—omens are distinguished as "ostenta, portenta, monstra, prodigia," because "ostendunt, portendunt, monstrant, prædicunt."

"SS. Biblicæ,"* "SS. Virgilianæ,"† etc.], and the calculating of nativities from the rising of the "Sidus Natalitium" by astrologers.

In India, omens thus discriminated and classed are a division of the sacro-sanct science of *Jyotisha*, or Astronomy; so called from Jyoti, "the Shining," one of the epithets of the Lord Siva; and every Hindu who aspires to a redeeming mastery of "the four Vedas," or Books-of-Sacred-"Knowledge" [*cf.* "wisdom," "wit," "witch," etc., and the Greek εἴδωλον, "an image," ἰδέα, "idea," and Latin *visus*, "vision," and *videre*, "to see"] has concurrently to study "the six Vidangas," or "Bodies" supplementary-to-the-"Vedas"; of which "Astronomy" is the most widely known, including, as it does, mathematics, astrology, horoscopes, omens, and palmistry. Every Hindu village has its hereditary *Jyotishi*, *Joshi*, or Astrologer and Diviner, and, indeed, its general guide, philosopher, and friend: who each successive year writes up the Kalendar [*Panchanga*, "the Five Bodies," i.e., "topics" of the lunar, and the solar days, the lunar asterisms, the division of the lunar days, and the transits and conjunctions of the planets] by which all religious festivals and other solennial observances are fixed, and all agricultural operations regulated, and wedding-days are arranged, and nativities cast, and fortunes foretold, and omens in general are interpreted. He combines in himself the Roman Astrologus, Mathematicus, Genethliacus, Horoscopus, and Auspex Nuptiarum, Haruspex, and Augur. In a word, he is the village Oracle; and delightful good company, with his hid treasure of priceless ancientries, for every distinguished stranger passing his time-worn way, if but he can speak your language, or you his. In view of the ignorant detraction of him, and his tribe, by the more illiterate class of our Protestant missionaries in India,—thinking of the dictum of Julius Hare, "The Christian is God Almighty's Gentleman," he (Sir George Birdwood) always read it, "The Gentleman is God Almighty's Christian"; a version, after all, nearer to the original line in "Absolom and Achitophel," "His tribe were God Almighty's Gentlemen." Of course his sacred office, that rightly can be held only by one of "the twice-born castes," lends itself to charlatanry and roguery of every degree; and therefore its incumbents are expressly forbidden to interpret omens, as they are also forbidden to teach the *Shastras*, "Vedangas," and Vedas, for a fee; while those who do so, and those not of the four "twice-born castes" who usurp the office, are numbered with informers, horse-trainers, dog-fanciers, teachers of fencing, etc., and are universally despised, just as by the Romans was "the starveling Greek" of their high day [Juvenal III.] who played the part at once of—

> Grammarian, painter, augur, rhetorician
> Rope dancer, conjuror, fiddler, and physician.

Strictly speaking, the regular, hierarchical *Jyotishi* or *Joshi* should be a Brahman; and in Hindustan is generally a Brahman, but in the Dakhan he is almost everywhere a Sudra. The great book in the Dakhan on Auspices and Auguries is the *Pancha-Paksha-Shastra*,* or "Five-Birds-Canon," that is, "Rule of Divination, by the Cock, the Crow, the Kite, the *chakora* or "Indian Cuckoo," and the Peacock, and, in practice, any other "kenspeckle" bird: and it is interesting to note that among the Romans the principal birds that gave omens by singing [*oscines*] were the raven [Apollo], the owl [Minerva], the crow, and the cock, and by flight [*alites*, or *præpetes*], the eagle [Jupiter], vulture, hawk, screech-owl, osprey, and buzzard [*cf.* Statius, "The Thebaid," iii. 502 *et seq.*: Cicero, Divin. liii.:—"Tum hic, tum illuc volent alites; tum a dextra, tum a sinistra parte canant oscines:" also the footnotes by J. Tollius, in Blaev's edition of Ausonius, Amsterdam, 1671, pages 489–90, on the line in "Technopægnion":—"Quadrupes oscinibus quis jungitur auspiciis?—Mus."]. But having been very much preoccupied while in India as Honorary Secretary to the Agri-Horticultural Society of Western India, in laying out the Victoria Gardens in Bombay, and carrying out their agricultural experiments at Poona, his (Sir George Birdwood's) greater interest while so engaged was in the œonology of Indian plants. There is no Indian canonical *Shastra*, or Book-of-"Instruction," on arboreal and floral omens; but in the works on astronomy, or *Jyotisha*, attributed to Varauha Mihiram, the one of "The Nine Gems of the Court of King Vikramadilya" who is credited with the statement that "sun-spots are ominous of imminent famine," numbers of omens from plants are given. He (Sir George Birdwood) had never seen any of this mythical Varauha Mihiram's writings, such as the *Brihat Samhita* ["Treatise" on the planet "Jupiter"], and the *Brihaj Jataka* ["Treatise on Nativities"], but many of its omens became known to him through Dr. Bhau Daji and the Rao Sahib Vishvanath Narayan Mandlik, and the Hindu Superintendents [*Karbaris*] of the Bombay and Poona Gardens; and nearly all of them relating to plants were in this form:—If such and such a "kenspeckle" wild plant were at any time in such and such a condition, such and such would be the following fate of the crop, tree, or flowering plant in which you were interested. For example:—"If bent grass flowers, there will be a great crop of sugar-cane." Others were of wider scope, as in

* The *Bathkol* of the Jews, according to Sir R. P. Jodrell's "Illustrations of Euripides."

† Charles I., in some conjuncture of his troubles, turning to his Virgil, opened it at Æneid iv. ll. 615 *et seq.*, and, in the doating Dido's furious cursing of her fugitive lover, read, in its full malignancy, his own foredoomed and irrevocable fate.

* Not to be confused with the Panchatantra, "Five-books," compiled in the 5th century A.D., by the Brahman Vishnu Sarman; but originally, in all probability, a Buddhistic work, it being nothing less than a veiled attack on the Brahmans. We know it best in the form of "Pilpay's Fables."

the following illustrations:—"If the *Champaka* flowers well, every crop will do well":—"If the 'Mango' fruits prolifically, every one will prosper":—"If the Wood-apple flowers, there will be storms about":—"If the Marking-nut flourishes, there will be fear in men's hearts of evil to come": —"If the Catechu spreads itself out and blossoms abundantly, there will be famine in the land":— "If the *Barringtonia speciosa* richly blooms, plague and pestilence will follow":—"If the Blue Lotus flowers, the country will be invaded by a foreign army." Obviously such omens are not idle and vain mystifications, or again, arbitrary "survivals," and gradually he (Sir George Birdwood) became convinced that they were founded on an overwhelming induction of facts, observed with untiring solicitude, albeit imperfectly observed,—judged by our present scientific standards of research,—and from generation to generation, and century after century, through at least three millenniums; and that they were just as honest in intention, and true in inspiration, as the forecasts of solar and lunar eclipses, and planetary occultations, and the dread visitations of comets. He (Sir George Birdwood) would not say this of the following plant omen:—"If the Sarsaparilla flowers well,—dancing-girls will have a fine high time of it." But at least this may be said of all widespread and enduring omens of the sort, that, although they have outlived their original significance, and become useless for all the practical purposes of a work-a-day world, and apparently unmeaning "survivals," the observance of them is still of advantage,—in the promotion of the continuity of folk-lore, and folk-culture, and of that reverence for the past which is the groundwork of all culture, and above all, as "means of grace" in the evolution of spiritual-mindedness, among the peoples who from the darkmost abysm of the past, have grown up with them into the wider spread, and, we will hope, brighter and happier light of the present-day world.

Mr. Leslie Moore has well shown how closely the omens of the Hindus resemble those of other races,—not only of the Japethic or Aryan race, but of the Semitic and Hamitic. The truth is, that the most notable of them have come down to us from millenniums before the division of the once universal, so-called Scythian, race, or Noachians of the Old World, into Semites, Hamites, and Aryans. Sneezing has always been regarded as a strong omen, and, in the main, for good. The Bible is full of reference and allusions to astrologers, charmers, diviners, exorcists, magicians, sorcerers, soothsayers, oracles,* but all through it, including the Apocrypha, no one sneezes. In the "Odyssey," xvii. 541–5, we read how Penelope, at first doubting the story of the return of Ulysses, disguised as a beggar, on Telemachus at the end of it giving "a great sneeze," regarded as a confirmation of its truth, and instantly cried out exultantly:—"Come, call in the stranger, that not one be spared of the suitors to be slaughtered." Aristophanes in "The Frogs"—on Æacus crying out to Bacchus:—"Assuredly I struck you," makes Bacchus reply:—"Then why did I not sneeze?" And in "The Birds"—we read:—"With you a word is 'a bird,' and you call a sneeze 'a bird,' a sudden meeting 'a bird,' a servant 'a bird,' an ass 'a bird'" [*i.e.*, they were each one an omen, or ὄρνις—as in Latin are *avis* and *ales*]. Theocritus, viii., has:—"On Simichidas the Loves have sneezed"; and, xviii.,—the "Epithalamium of Helen":—"O happy bridegroom, some benignant spirit sneezed on thee a blessing." Catullus, xlv., on Acme and Septimus, records:—"Love who at first had regarded him [disdainfully] from the left, now sneezed approvingly from the right": and similarly sealed Acme's passion for Septimus with another "sneeze from the right." Propertius, ii. 3, asks:—"In thy new born days, my life, did Love sneeze, sharp and clear, a favouring omen?":—

"Aridus argutum sternuit omen Amor?"

Pliny, ii. 40 (40) tells us that at the rising of the Dog Star, the Egyptian Oryx stands facing it, steadfastly sneezing at it, as if worshipping it. Again, xxviii. 5 (2) he asks:—"Why when one sneezes do we salute him? an attention the Emperor Tiberius Cæsar, the most dismal of men, invariably exacted from those about him." That is quite a Gilbertian "scena"! The Greek salutations were "Ζῆθι!"—"Ζεῦ, σῶσον!" [Ausonius, "Griphus," p. 455]. "Deus te adjuvet" was the Latin one of Mediæval Europe; the German Mr. Leslie Moore has given us; and we all knew the English:—"God bless you." Indian œonology is full of sneezing; and a common saying among Hindus, when anyone suddenly, and for no apparent reason, changes his mind, is:—"Did a fly sneeze?" It is worthy of being naturalised in Europe, if, indeed, it is not already domiciled there somewhere. Also it is a great social art among Indians to convert a bad into a good omen, after the manner of Julius Cæsar, of whom Suetonius [59] tells us that stumbling—a direful portent—on the seashore, when landing with his invading army at Adrumetum, he at once kissed the ground, and, at the same time gathering up a handful of the soil, exclaimed triumphantly as he arose to his feet:—"Thus I take prize of Thee, O Africa!"

The close relationship of the omens of the Greeks and Romans to those of the Hindus is, of course, due not only to the prehistoric connection between them before they migrated from their original home—somewhere about the Caspian Sea—Westward and Eastward, respectively, but to the interchange of omens among them, after they had become separate, and great, and renowned nationalities, with differentiated languages, literatures, arts, and religions; an interchange that had grown so intimate by the period of the Cæsars, that Armenius, Babylonius, Comagenus, Chaldæus and Indus, were then Roman synonyms

* II. Samuel xvi. 73:—"Oracle," means, "The Word of God": in the New Testament invariably the Mosaic Law.

for *astrologus*, *auspex*, *augur*, *haruspex*, etc.; and, as he (Sir George Birdwood) had often said before, the glory of the reign of Augustus Cæsar and his immediate predecessor and successors, that was above all the glory of Cicero and Virgil, and Horace, and Ovid, and Pliny, etc., became reflected throughout India by the still vivid and vitalising legend of "The Nine Gems of the Court of King Vikramadilya." And some day it will be demonstrated that the legendary Varauha Mihiram, of whom he had already spoken was, in the flesh, none other than his own first and last official and journalistic inspiration and despair, the Elder Pliny,—amalgamed, in diminishing proportions, with Cicero, the philosophical Augur, and Claudius Ptolemy the Geographer, and Astronomer, and Aratus, the Laureate of the Heavens:—

"In restless Gyres about the Arctic Pole."

Mr. K. G. Gupta, C.S.I., said he could not understand how it was that an Indian had been asked to speak, unless it were a cunning device of the Secretary to present before the audience a live specimen of that unfortunate people called Hindus, who had been credited with the long catalogue of superstitions with which the author had regaled them. He wished the author had placed some limitation upon the word Hindu, because he evidently referred to what he had learned in his experience in Bombay. Many of the observations which were made with regard to the Hindus generally did not apply, at any rate, to Bengal from which he (the speaker) came. He would take only two examples to prove that. The first was when the author said that the European was credited with the evil eye. Personally he had never heard of it in Bengal, where he was born and brought up, and lived for many years. But there might be a reason for having that belief in some places because of the difference in the customs of England and India. All those who had been in India knew that Indian mothers did not like their children to be praised in any way; they did not like them to be called plump, sweet or healthy. But in this country the custom was just the reverse. If anyone wished to please a mother, he could not do better than bestow commendations on the child. It might have happened that in India some English lady, not knowing the Indian custom, might have spoken well of the children of her hostess, and the hostess had taken the compliment in a different light. It was quite possible that, by a strange coincidence, some harm had befallen the children, so that one could easily understand how a European would be credited with the evil eye. In the second place, he had never heard the suggestion made previously that an Englishman was regarded as a descendant of Hanuman. Having regard to the extreme energy of the average Englishman, his agility in the tennis-court, or cricket-field, or in the ball-room, it was possible that in some parts of India he might be considered as being descended from the ape. In that connection they were on very solid ground, because, according to the most approved theory, they were all descended from apes, and he, therefore, thought the Hindu gave the Englishman very great credit, because he did not regard him as a descendant from an ordinary ape, but from Hanuman, the Lord of Monkeys. Hanuman was the ally and friend of Rama, one of the great Indian deities; he assisted Rama in civilising and Aryanising Ceylon, and he was a loyal, thoroughly good and kind ape. He was so loyal that when his loyalty was once questioned he tore open his breast for everybody to see that on his heart was written the name of his friend and patron Rama. If they had to admit that they were descended from apes, surely the best thing that could possibly happen was to be descended from the best of the apes, so that there was nothing discreditable about it at all. Coming to the question of superstitions, what were superstitions? Did not they represent the exercise of that faculty which had brought all human knowledge, *i.e.*, the inductive faculty? All the highest achievements of science were due to that process. Superstition was an inference drawn from one or two coincidences. It was faulty in that sense, but it was the result of the same process. It could easily be imagined that, in the early days of humanity, when a hunter started out in the morning to find food for the day, he saw a jackal on his left-hand side, and that on that day he was unsuccessful. The next day when he started out the jackal was not there, and then he was successful. On the third day, unfortunately, the jackal happened to be there, and again he met with failure. Naturally he would go home and think that the jackal on his left-hand side must have had something to do with his non-success. He would tell that to his friends and relations, and so the superstition would gradually get abroad. Probably some other men would have the same experience too, and it would be regarded as a fact inductively proved. There was the jackal, and there was the want of success on three or four or five occasions; therefore their relation as cause and effect must be a fact. That instance of inductive reasoning was no doubt faulty, but once the superstition was well established those who believed in it did not take heed of the want of proof in other cases, but only took note of those cases where the coincidence happened. It was due to the inductive process hastily carried out and the naturally innate conservatism of the human mind that superstitions had gradually grown up and spread. And, after all, what was true to-day might be superstition in the near future. For instance, in the highest principles of science, what people believed to be perfectly true to-day, fifty years hence would probably be called superstitions. As knowledge progressed, the theories which were held to be absolutely proved at the present time would in a generation or two be regarded as quite superstitious. The word superstition did not carry one very far. What was called superstition really represented different stages of ignorance. As

people grew in intelligence they left superstitions behind. They had done their work for the day, and they were doing their work now for different stages of society. All people were not on the same level of culture, enlightenment and education. Those who were still children could not be taken straight away to the university and given the highest education. Similarly, human beings who had not yet advanced forward liked to play with what more cultured people regarded as superstitions, although they would gradually overcome them as education advanced and enlightenment grew. It was not right to laugh at superstitions, because they were doing their work for the time, and they would be gradually discarded as any particular class of people or race advanced in enlightenment. In that way he thought superstitions had their uses. The particular superstitions to which the author had referred did not, he thought, have very much to do with religion; they related to actual experiences in life, and had not so much to do with the spiritual side of life and what would happen hereafter. That was another kind of superstition with which he did not think the author had dealt.

Mr. M. Longworth Dames said his own experience in India had been in an entirely different part from that dealt with by the author, namely, on the North-West Frontier. As most of those present knew, beliefs varied in different parts of India, but there was often quite as much in common between the beliefs of a country as there was between the beliefs of entirely different countries. Many of the superstitions to which the author had referred could be paralleled just as well in Europe or other parts of the world. He called to memory a belief which was held about the Bhuts on the North-West Frontier. There was a place not far from his house which was believed to be haunted by a Bhut, and which it was dangerous to pass by at night. A man went past it one night and was then found to have a hump on his back, the statement being made that the Bhut had jumped on his back and stopped there. There was also an Irish story of a man who passed a haunted castle, when the Phuca sprang on his back and stopped there, and he became a hunchback. The author had referred to the superstition of eating the earth from saints' graves. He came across a similar case in Ireland, in King's County, where the people of the district visited a priest's tomb and were gradually eating all the earth from that tomb. He remembered also a particular kind of omen that existed among the Baluchis on the North-West Frontier. According to the Baluchis it was a very unlucky thing to see a particular bird, a sort of shrike, on one's left-hand side on starting a journey. Should such a bird be seen it was necessary for the travellers to go back and make a fresh start. But if the party happened to be going out shooting it was a favourable omen to see the bird on the left-hand side, because it meant blood, and the shooting party could proceed. He remembered once receiving an official report from the local police officer in the district he was administering saying that a widow and her family, who did the scavenging for a small bungalow in the district, had been driven out of their house by a Djinn. His orders being requested on the subject, he told the officer to provide another house for the widow and her family for the time being. When he visited the place he heard the statement of the widow and of the surviving children, one of the children having already been killed by the Djinn, while the others were perpetually frightened out of their lives. They lived under a small stunted tree, the hut being almost under the boughs of the tree. The children used to play under it, but whenever the mother was away the Djinn used suddenly to spring out and dreadfully frighten them. He (Mr. Dames) proposed to cut down the tree, in order to remove the Djinn, but his proposition created the utmost consternation, because the people said the Djinn would take a frightful revenge. Accordingly the house remained unoccupied, and a separate house had to be provided for the widow and her children. Another curious belief in that part of the country was that the Djinn sometimes took the appearance of devils seen travelling across the plains in hot weather. As a rule Mohammedans believed they were the souls of unbelievers, especially Hindus, who were compelled to live a wandering life as they had never accepted a proper faith. Personally he had seen ten or a dozen columns of dust and sand crossing the plain at the same time, and they certainly had a very ghostly appearance.

Mr. K. Vyasa Rao said he had always tried to look at Indian superstitions from the point of view of the outsider. It struck him that Indian superstitions had in them a basis quite different from the basis of superstitions that existed in other countries. One very interesting superstition which the author had not mentioned was that in regard to pollution. When a death occurred in a Hindu household the members of that household, even though some of the relations might be living hundreds of miles away, had to observe pollution for ten days. That rule was nowadays seen in the wholesome principle of segregation, because during the time of pollution no member of the household was permitted to enter a house, or to be in any sort of social communion with the members of that house. When the plague occurred in Bombay and other places in India, the principle of segregation was carried out in exactly the same way, but that principle of segregation had been thought of and adopted centuries ago in India. Another great superstition to which the author had referred was in regard to the occurrence of an eclipse, it being thought that the eclipse of the sun and the moon was due to two snakes or serpents. Whenever an eclipse took place Hindus were compelled to go out of their houses to the rivers and tanks and have a bath, just at

the time the eclipse began and concluded. It would be found that two thousand years ago Indian astronomers were so well acquainted with astronomical matters that they were able to fix the time and place of an eclipse, and nevertheless by the side of such great scientific ability there was such a silly superstition, in which people believed, as that two snakes came and swallowed the sun and the moon at the time of an eclipse, and that they must, therefore, go and have a bath. The reason that the people had a bath at the time was that they feared during the eclipse there might be some seismic disturbance, and that it would be a precautionary measure on their part to leave the house and be in the open at the time. Another superstition to which the author had not referred was the wonderful power certain Indians possessed in the art of curing snake bites and scorpion stings. If a man was stung in the ankle the poison gradually ascended his body; but as soon as the poison-curer began to pour out his incantations, the poison in the armpit began to descend and go slowly down until it came to the actual spot where the original sting was, and then it disappeared altogether from the place of the sting. That was done even at the present day, and no scientist or psychologist had been able to explain the wonder of it, or how it was possible that a man, simply by means of incantations, was able to get rid of poison in another man's body and altogether relieve him of illness. Under the name of superstition there were sterling gems of the purest ray which would lead to a better appreciation of spiritual beliefs.

Sir ARUNDEL T. ARUNDEL, K.C.S.I., in proposing a hearty vote of thanks to the author for his interesting and instructive paper, said he thought Mr. Gupta's contribution was one of extreme value, as it endeavoured to get at the underlying principles of the superstitions to which reference had been made. He wished to be allowed to refer to one curious experience in regard to the superstition that existed as to the killing of human victims for placing in the foundations of bridges, to which the Chairman had referred. Near the place where he was Collector, a large bridge was being built across the River Kistna. There was a great dam across the river, and a broad canal, which severed the town from a large stretch of land between the canal and the river. Rumours had been going about in the town, for some time past, that sacrifices were to be offered. It was even rumoured that the engineer-in-chief, Mr. Spring, had had a letter from the late Queen Victoria mentioning the number of babies who were to be put in the foundations of the bridge. In the tract between the canal and the river there was a large colony of Punjabis, who had been imported specially by Mr. Spring to carry on the work, and a number of those Punjabis used to go over a narrow bridge, leading across the canal, into the bazaar, and buy what they wanted. One of them was in the bazaar one morning, and seeing a woman there selling sweetmeats, he went and bought some from her. The woman had a baby in her arms, and in order to ingratiate himself with her, the Punjabi took the baby in his arms purely for that purpose. He had no sooner done so than a woman on the other side of the bazaar shouted out, "Baby snatcher!" and in a moment the whole town was in an uproar. The argument of the villagers was that one of the Punjabis had actually been seen with the baby in his arms, and that the sole object for which he had possession of it was in order that it might be sacrificed to be put in the foundations of the bridge. The uproar was on the point of turning into a great riot, but it was ultimately quelled through the tactful interposition of the chief engineer, assisted by the native magistrate, who had to be fetched from some distance.

Sir JAMES WILSON, K.C.S.I., in seconding the motion, related an instance in which he had the misfortune to come into conflict with a Bhut. In some parts of the Punjab there were large *tumuli*, ancient burying-places, which were supposed to be the graves of the *naugajas*, giants who were nine yards long. On riding into a new camp one day, a little to the north of Delhi, he was met by a deputation of the headmen of the village, who were evidently greatly disturbed. They explained to him that his tent-pitchers had unfortunately pitched his tent close to one of the graves of the *naugajas*, and that they did not like it at all. He replied that he was very sorry to hear it, and that, if they objected because they thought it was a holy place, he would give orders to have the camp removed. The headmen replied that it was not a sacred place, and that personally they did not mind, but they were afraid of the consequences to him. They explained to him that the *naugaja* was a very dangerous person, and that he would probably resent anybody trespassing upon his ground; but he (Sir James) replied that, if that was all, he would risk it. In the middle of the heat of the day there was a tremendous uproar in the camp, and on making inquiry he discovered that a rotten tree standing in the middle of the camp had suddenly caught fire most mysteriously. All the people and his own servants swore that nobody had gone near it, and that the outbreak was the giant's first indication of the trouble he intended to bring upon them. In the middle of the night a whirlwind blew right through the camp and very nearly blew his tent down; the Government official tent was blown down, and the Government official table was broken. The villagers, of course, put that down to the action of the *naugaja*, and he had no doubt they were still more convinced than ever before that the *naugaja* was a dangerous fellow.

Sir GEORGE BIRDWOOD said he rose simply to confirm Mr. Leslie Moore's statement that the belief prevails among the Hindus, at least in the Presidency of Bombay, of the English being

descended from the Indian Monkey God, Hanuman [" Long-jaw "]; but whether it was to be regarded as implying compliment or contempt would depend on the feeling and thought of the person at the time of giving expression to it: for the Hindus, like all the quick-witted people of Southern Eurasia, from Greece to India, have a wonderful way of conveying praise and blame, blessing and cursing, in the same words; of which the best illustration, albeit unintentional, known to him, was the "Authorised Version" of the Biblical text:—"O fools and slow of heart to believe all that the prophets have told you." The "Revised Version" is even more clearly double-edged, and is only to be rightly understood by substituting the word *after* for "in" between "to believe" and "all." It is the Hill Tribes of South-Western India who are personified in "The Ramayana" by the simious subjects of the heroical Hanuman; and spoken by a Hindu, in the plain sense of the words, the tradition referred to by Mr. Leslie Moore could have been repeated to him only in the spirit of the sincerest praise. A common Hindu saying in Bombay is:—"Even the High Gods themselves delight in flattery." *

Mr. Leslie Moore, in replying to the discussion, said Mr. Gupta was perfectly right in saying that he (the author) was not careful enough in using the term "Hindu." He ought to have said "Bombay Hindu" more frequently than he did. Sir George Birdwood had supported him in the statement that Englishmen were descended from Hanuman, the Monkey God, and Mr. Gupta had pointed out what a glorious ancestry that was. Mr. Gupta had stated that the evil eye superstition did not exist in Bengal. It certainly existed in Bombay, and he thought that it must also exist in the Punjab, to judge from the story by Rudyard Kipling which had been told them about the Punjab. Mr. Vyasa Rao had mentioned some interesting superstitions that were not referred to in the paper. As a matter of fact he (the author) started his paper by saying that it would be impossible to read an exhaustive paper on Indian superstitions, because to do so would take a very much longer time than was at his disposal. He presumed that Mr. Gupta had spoken in a joking mood, but he assured that gentleman that he wrote the paper in anything but a critical frame of mind. It would be absolutely absurd for any Briton to criticise Hindus about their superstitions, for the simple reason that Britons were probably sunk quite as deeply in superstitions as the Hindus were. It was only necessary to remember the superstitions about fairies in Ireland, pixies in Devonshire, and brownies in Scotland, for it to be manifest that superstitions were quite as deeply rooted in Britain as they were in India, and to his own mind they were certainly not more picturesque.

* In this connection there is an interesting correspondence under the heading:—"Sir Charles Crosthwaite on India" in the *Times* of the 4th, 6th, and 7th October last.

ELEVENTH ORDINARY MEETING.

Wednesday, February 22nd, 1911; Alan S. Cole, C.B., in the chair.

The following candidates were proposed for election as members of the Society:—

Brichett, Dr. J. G., Cardwell, Missouri, U.S.A.

Bruch, Walter W., 64, High Holborn, W.C.

Converse, Edmund Cogswell, Conyers Manor, Greenwich, Connecticut, U.S.A., and 72, Broad-street, New York City, U.S.A.

Down, St. Vincent Bowen, Winchester House, Singapore, Straits Settlements.

Gladwell, Arthur, Brynmaur, Gerrards Cross, Bucks.

Harvey, Ernest William, F.C.S., The British Empire Club, 12, St. James's-square, S.W.

Hastings, Percy, The Cottage, Wimbledon-common, S.W.

Moitry, Manmatha Nath, Serampore, Hoogli District, Bengal, India.

Williams, Stacy B., Brockweir, Urmston, near Manchester.

The following candidates were balloted for and duly elected members of the Society:—

Crook, Thomas Mewburn, R.B.A., 10, Gainsborough-road, Bedford Park, W.

Genge, Henry Arthur Pope, Ootacamund, Madras, India.

Green, Richard Crafton, Newport, Essex.

Grundy, Cuthbert Cartwright, R.I., R.C.A., Home-field, Blackpool, Lancashire.

Gummá y Marti, Alfredo, Calle Universidad 30, Barcelona, Spain.

Heys, John, Heysham, Marine Approach, South Shields.

Lawrance, Dilipa John Skillern, 16, Infantry-road, Bangalore, India.

Lawrance, John C. Skillern, B.A., LL.B., Kirkton, 16, Infantry-road, Bangalore, India.

Lloyd, William, 29, Bridge-street, Staines.

Pott, Miss Constance M., 81, Cornwall-gardens, S.W.

Smith, Alexander Monro, 2, Denton-road, East Twickenham.

The paper read was—

EXPERIMENTS WITH "WATER-FINDERS."

By Professor J. Wertheimer, B.Sc., B.A., F.I.C., F.C.S.,

Principal of the Merchant Venturers' Technical College and Dean of the Faculty of Engineering in the University of Bristol.

In the Cantor Lecture on "Mine Surveying," in 1892, Mr. Brough placed before this Society a brief sketch of the history of the use of the divining-rod, more particularly for the purpose of finding metal. There are now, and have been

for many centuries, hundreds of people who believe firmly that, by the use of the rod, certain persons are able to find not only metals but also water, coal, and, as a recent wielder of the rod (Mr. Edwards, the sexton at Rodney Stoke) alleges—corpses! The rod has also been used quite recently to track persons, and at one time was largely in use for the purpose of finding criminals.

There is abundance of well-authenticated evidence that "Dowsers" or "Jowsers," as waterfinders are termed in the West of England, have repeatedly indicated spots where good supplies of water have been found. The object of my experiments was to ascertain whether or not these indications were caused by any influence outside the "Dowser," or whether he unconsciously gave indications not caused by anything external to himself. An attempt was made to induce all the well-known waterfinders to take part in the experiments, and the conditions were arranged beforehand, so that the powers of the waterfinders might be tested in a way that appeared to them to be fair.

Many of the professional "dowsers" declined any test except the very expensive and quite inconclusive one of "finding" water by means of the rod, etc., and then sinking wells to ascertain the accuracy of these indications. In such a "test" one cannot, of course, eliminate the possibility that in many parts of the country, especially those in which waterfinding flourishes, it is rather more likely than not that water will be found in any place chosen by a man having a knowledge of the conditions under which water is usually found. Moreover, if a well be sunk and no water is found at a certain depth, the waterfinder can always state that this is due to the well not being deep enough.

The methods of "dowsers" vary considerably; some use a twig, others a watch-spring, while one of the best with whom I experimented required neither twig nor spring. The conditions which they regard as essential also vary to a remarkable extent; some can find water only through the earth, others find a stone floor or a piece of linoleum no hindrance. Some can detect water in movement only; some allege that the presence of iron or coal is a hindrance; some can find running water in an iron pipe; others state this is impossible. This makes experiments with "dowsers" exceptionally difficult, since the conditions acceptable to one may be applicable to him only.

The experiments I am about to describe deal mainly with the finding of water, but some of them were directed to ascertain the value of the claims of certain "dowsers" to find gold or silver, while one experiment had in view a test as to the accuracy of the "dowser's" opinion that the external influence which caused the motion of his rod was electrical in character.

(A) Experiments to Find Water.

I. *At Brislington Hall.*

In the kitchen of this house there is a deep well with a constant supply of water, situated near the fireplace approximately at W, as shown on the plan, Fig. 1, which is roughly to scale. Three "dowsers" were, by kind permission of Mr. A. C. Ireland, J.P., taken to the Hall and asked to discover the position of this well by means of their rods. One of these—Mr. Chennels—indicated three spots in the kitchen marked respectively, C_1, C_2 and C_3, but failed to give any indication when over the well itself; but when told where the well was, he discovered the

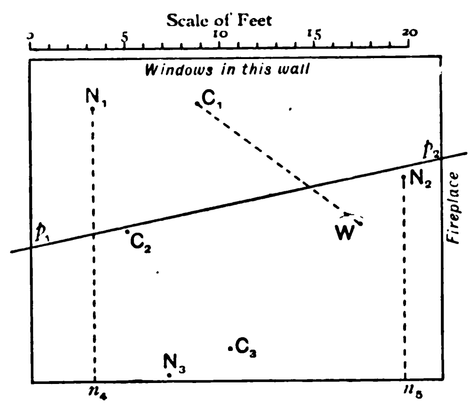

Fig. 1.

existence of a course of water running from C_1 to the well.

Another—the Rev. W. F. Newman, M.A.—got indications at three points, N_1, N_2 and N_3, and likewise traced two lines, N_1,n_4, and N_2,n_5, along which he supposed that there were underground streams of water. The third waterfinder—Mr. R. Pavey—drew a number of lines indicating the underground channels which he found, and one of these—p_1,p_2—like Mr. Newman's line N_2,n_5, passed close enough to the well to be regarded as a success, but, as will readily be seen, the indications of these three experienced "dowsers" are absolutely at variance with one another; if they are all correct, Mr. Ireland's property would be a very valuable investment for a water company.

II. *Experiments at Teddesley, Penkridge, Staffordshire.*

These experiments were performed by Mr. G. Roberts over a tiled drain in Lord Hatherton's Park at Teddesley. This drain is a few feet below the surface, and at the time of the experiments there was an abundant flow of water through it. The object of the experiments was to ascertain whether or not Mr. Roberts's rod moved invariably when passing over an underground stream of water. Mr. Roberts passed

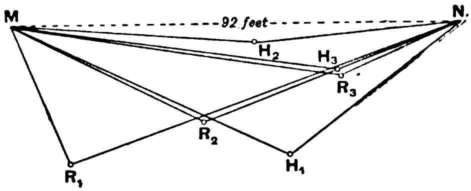

FIG. 2.

over the drain six times in all, three times his rod gave indications, but on the remaining three occasions the rod did not act when Mr. Roberts was on or near the drain; this proved that Mr. Roberts's rod does not turn with any certainty when over running water.

The rod indicated in a large number of places; certain spots where a number of indications were obtained within two comparatively small areas were carefully marked by stakes, their positions accurately measured and an amateur waterfinder—Sir Richard Harrington—who did not witness the experiments performed by Mr. Roberts, was subsequently taken to the two parts of the park in question, and was asked to re-discover the points indicated by Mr. Roberts. The results are plotted for one part on Fig. 2: R_1, R_2, and R_3 are the points indicated by Mr. Roberts; H_1, H_2 and H_3 are the positions selected by Sir Richard Harrington. In this case it will be seen that there is only one position in which there is an approximate agreement.

In regard to these experiments it is, however, right to say that, while Mr. Roberts was allowed ample time for his indications, Sir Richard Harrington had to make his tests speedily.

III. *Experiments in the Grounds of Downside Abbey.*

These experiments were performed by Mr. Rowland Pavey, who pictured to himself the hollows in the ground which contained water, and traced lines on the surface representing them. It was a condition of the experiment that lines traced elsewhere than where the known wells were situated were not to count, and Mr. Pavey was successful in finding the wells, as will be seen from Fig. 3; but Mr. Pavey drew so many lines, most of them curved, that it seemed to me probable that anyone drawing a similar number of lines at random would have drawn at least one which would pass through the well or spring to be detected. In stating this, I wish it to be under-

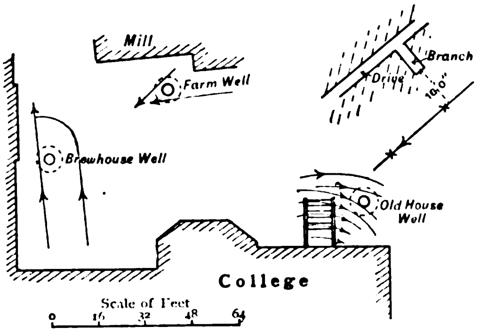

FIG. 3.

stood that I am perfectly satisfied that Mr. Pavey, whom I believe to be an honourable man, did not draw the lines in the way mentioned with any intention to make success certain in this way; on the contrary, I feel sure that he really believes in his possession of the powers he claims, and that the channels he traces have an actual existence.

IV. *Experiments in West Town Lane, Brislington, near Bristol.*

I put before Mr. Pavey my reasons for undervaluing the success he had obtained, and asked him whether his rod would indicate the presence of flowing water in an iron pipe. His reply was in the affirmative, and in the following experiments he was asked to stand over a water-main buried in the earth through which a large quantity of water was flowing. By the kindness of the chief engineer of the Bristol Waterworks (Mr. J. A. McPherson, B.Sc.) arrangements were made by which, at times unknown to Mr. Pavey, the flow of water was stopped, and Mr. Pavey was asked to ascertain when the water ceased to flow and when it began to flow again.

As shown on the accompanying plan, Fig. 4, a three-inch water-main passes through the lane in question; it is controlled by the three-inch sluice valve, shown on the plan, at the West Town end of the lane. The sluice valve was kept open the whole time, thus ensuring that the main was full of water, while the hydrant was opened and closed at fixed times. About five seconds were required to open and close

the hydrant; when the hydrant was opened there was a rapid flow of water through the three-inch main, while when it was closed the water was still. Mr. Pavey had stated that he was not affected by still water, but was affected by running water, whether contained in iron pipes or not.

In order to ensure perfect accuracy of working, a man was stationed at the sluice valve to see that it remained open during the whole time of the experiments; he was accompanied by a student of the Merchant Venturers' Technical College as a witness. The man whose duty it was to open and close the hydrant, was supervised by a foreman of the Bristol Waterworks and another student of the College; Mr. Pavey's observations were timed by Mr. McPherson and myself. Before commencing the experiments the watches used by the foreman, the student

Mr. Pavey was of opinion that his failure was due to the fact that the water engineer and myself were near him, and that we had prevented his success. He, therefore, offered to undertake another series of tests, and backed up this offer by undertaking to subscribe £5 to the Bristol Hospital if he failed once out of ten times in stating correctly when the water was flowing

through the main or when it was not doing so; it was also a condition that if he succeeded I should pay the hospital £10.

The experiments were completed under the precise conditions required by Mr. Pavey, and the result of them is shown in the accompanying table:—

Mr. Pavey paid £5 to the Bristol Hospital, and has since published a book criticising the experiments from his point of view. It contains a number of statements of a mystic character, such as his claim to be able, by means of his "pantoscopic" faculty, to see the wings which he alleges human beings possess, and also to see the electric fluid passing through their bodies. He assumes, quite wrongly, that his failures are due to some telepathic action which I have exerted upon him. Not only can I lay no claim to the wonderful power which he attributes to me, but also I had no desire that he should fail. On the contrary, I should have been delighted if he had succeeded, as I should then have had a most interesting field for research in regard to an hitherto unknown force, the existence of which would have been proved.

(*B*) Experiments to Find Gold and Silver.

I. *Experiments with Mr. Chennels.*

When at Brislington Hall, Mr. Chennels was asked first to choose a piece of ground where his rod did not indicate the presence of water. Twelve saucers were then arranged on this ground and sums of money were placed under some of these, viz., either £3 in gold or at least 7*s.* in silver. In the first trial Mr. Chennels indicated over five saucers; under two of these only was there any money. But there was money under three of the saucers over which Mr. Chennels's rod did not indicate, so that Mr. Chennels was right in seven cases and wrong in five.

In the second test only seven saucers were used; Mr. Chennels's rod indicated over six of these; these indications being correct in three instances and wrong in the remaining three. Under the seventh saucer there was no money, so that in this instance Mr. Chennels was right in four cases and wrong in three.

Subsequently, he performed experiments in the Great Hall of the Merchant Venturers' Technical College; he was asked to make certain that the places where the nine saucers used were placed were ones in which nothing would interfere with the success of the experiment. Accordingly, he placed the saucers himself on the ground, and then did a blank test with each saucer, thus making certain that when no coins were under the saucers his rod did not move. The sum of 10*s.* in silver was then placed under each of four of the saucers; Mr. Chennels indicated over four saucers under three of which there was money. Since there was money under only one of the remaining five saucers, Mr. Chennels was right in seven out of nine cases. This experiment must, therefore, be regarded as a success.

Mr. Chennels thought that he could do better in the open, and the next experiment was therefore performed in an open space at the back of the College. The same precautions were taken as in the previous experiments, each saucer being placed by Mr. Chennels and a blank test being made with the rod, when Mr. Chennels obtained no indications over any of the twelve saucers used.

Mr. Chennels's rod subsequently indicated over each of the twelve saucers, but money had been placed under only two of them, so that in this instance there were ten failures against two successes. Mr. Chennels endeavoured to explain his failure by stating that in his opinion there was either a mass of water under the ground in question or a bed of coal at a depth, as he estimated, of 1,000 feet. He also found the existence of water or coal in a covered space under the Great Hall where, strangely enough, he had performed the successful experiment mentioned above.

After Mr. Chennels had discovered the alleged bed of coal at the College, he said he would

prefer to try an experiment elsewhere. He was, therefore, taken to the garden of the Merchants' Hall, where he placed five saucers in positions selected by himself, and again made a blank test with his rod, ascertaining that it did not act over any of the saucers. At his request, money was placed this time only under one saucer.

Mr. Chennels discovered this saucer by means of his rod, but when asked to repeat the experiment, was unfortunately too tired to proceed.

It will be noted that in the five experiments with coins described above, Mr. Chennels obtained a large measure of success in two cases only.

II. *Experiments with the Rev. W. F. Newman, M.A.*

Eight cushions were placed on the floor of the dining-room at Brislington Hall; two sovereigns were placed under each of two of these cushions. Mr. Newman was then invited to find under which of the cushions gold was placed. In two cases he said there was gold under the cushions when this was not so; in a third instance he said there might be gold under the cushion, but was not certain. This was one of the cushions under which gold had been placed. He said there was no gold under the remaining five cushions, but there were two sovereigns under one of them. It will be seen from these results that the indications given by the rod were inaccurate. As Mr. Newman had previously obtained no indications with his rod over the places where the cushions were placed, it is, in my opinion, fairly certain that the vigorous movements of the rod which resulted in this test were due to subjective causes.

(*C*) Experiment to Ascertain if the Motion of a Dowser's Rod is Due to an Electrical Cause.

In the course of our correspondence, Mr. Newman expressed the opinion, frequently held by dowsers, that the action of his twig was due to some electrical cause, and that, if he was insulated from the ground, his rod would not act. I told Mr. Newman that experiments in this direction had already been performed, and that the results justified the belief that the motion of the rod was not due to such a cause. It was, however, decided to try the experiment, and Mr. Newman accordingly proceeded to choose a spot outside Brislington Hall where his twig gave strong indications; Mr. Newman was then asked to stand upon a stool carefully insulated, but so arranged that it could be connected to the earth without Mr. Newman knowing when this happened. Mr. Newman thought that the indications of the twig were not quite as vigorous when he was insulated, but he admitted that the difference, if any, between the indications given when he was and was not insulated respectively was so slight that it was useless for him to try to say when insulation took place or not—in fact, the result was that he was satisfied that the motion of the twig was not due to an electrical cause.

Conclusion.

Since these experiments were undertaken, I have received a large amount of correspondence and many publications in regard to dowsing in this country and abroad, but I have not been able to find any experienced dowser willing to submit to definite experiments, nor have I been able to induce the proprietors or agents for any of the instruments for finding water to submit these to a scientific test.

My opinion is that the motion of the dowser's rod and the sensations which he experiences are not due to any cause outside himself. On the other hand, I believe that when the dowsers with whom I experimented stated that they did not cause the rod to move, they were saying what they believed to be the truth, but were unconsciously misleading themselves.

DISCUSSION.

The Secretary read the following communication from Professor W. F. Barrett, F.R.S.:—I am glad that th3 subject of "Waterfinders" has been brought before the Royal Society of Arts, and regret my distance from London prevents my attendance. Having given to this subject many years of careful investigation, perhaps I may be allowed to make a few remarks. When a paper is read before a learned society on an obscure and controverted question, it is usual for the author to make himself acquainted with the history of the subject and acknowledge—even if he does not discuss—the investigations and conclusions of those who have previously explored the same field; provided their scientific standing and the precautions they have taken justify such an acknowledgment. Professor Wertheimer, however, has not thought fit to take this course, for what reason I do not know.

The author tells us that the object of his experiments was to ascertain whether the indications given by the dowser were due to an influence outside the dowser, or were purely subjective, and he arrives at the conclusion that "the motion of the dowser's rod and the sensations which he experiences are not due to any cause outside himself." This conclusion is based upon a few experiments with two professional dowsers, Chennels and

Pavey, and two amateur dowsers, the late Sir R. Harrington and the Rev. W. Newman, together with a dowser, Mr. Roberts, who is not further described.

The principal experiments were with Pavey and Chennels, and consisted of tests on still or running pipe-water and finding hidden coins. Whether such tests are of value in ascertaining the claims of dowsers to be waterfinders is a matter of doubt. Some years ago I requested Mr. E. Westlake, F.G.S., to conduct a series of experiments with Pavey and three other Somersetshire dowsers, to see whether their respective and independent indications of underground metallic lodes coincided or not. The results are given in an appendix to my last Report on Dowsing and published in the Proceedings of the Society for Psychical Research for 1900. It turned out that Pavey was only right about once in six, whereas another dowser, Day, was right in one half the trials. But the general result was inconclusive and of no evidential value.

The test of running pipe-water selected by Professor Wertheimer is not a desirable one. In the first place it is difficult to prevent some slight sensory indications arising from the sudden stoppage and reflow of the water, and in the next place the experiment has little bearing upon the main object of the inquiry.

Of the other professional dowser tested by Professor Wertheimer—a man named Chennels—I know nothing; I think were he a dowser of any repute I should certainly have heard of him. There are of course many persons who—finding a forked twig suddenly twist in their hands at certain spots—believe they have a peculiar gift of ore or water-finding, but are self-deceived. The unconscious and involuntary muscular action which causes the dowsing-rod to turn, is by no means uncommon, and is a familiar illustration of what is known as "motor automatism."

The qualifications of anyone who professes to be a dowser need to be tested, and his record critically examined, before wasting time in using him as the subject of serious scientific investigation. In this respect Professor Wertheimer has been singularly unfortunate, and whilst I welcome the interest he has shown in the subject, I do not think he has much advanced our knowledge in one of the most difficult regions of psycho-physical inquiry.

It is now some twenty years ago that, at the request of the late Professor Sidgwick and the Council of the Society for Psychical Research, I reluctantly consented to undertake an investigation into this subject. On *a priori* grounds it seemed to me far more probable that any success the dowser achieved was due either to the prevalence of water-bearing strata, a shrewd eye for the ground, or chance coincidence—than to any peculiar gifts he possessed. Moreover, it is well known how frequently failures are forgotten and lucky hits are remembered. Hence I was quite unprepared to find a remarkable body of evidence in favour of certain dowsers, notably the late John Mullins, and, after five years laborious investigation, I was driven to abandon the explanations I have just given as inadequate to cover *the whole ground*, though they are true enough in certain special cases. After publishing my first lengthy report, further investigations were made, with the aid of able and critical geological advice, and these were published in my second Report in 1900. Since then a bulky mass of additional evidence has accumulated, and will be published shortly. It is obvious I cannot give even the briefest outline of this evidence at the present moment. It is sufficient to say that if Professor Wertheimer, or anyone else, can give a more satisfactory explanation of this evidence than I have ventured to make, I shall heartily welcome it.

My own conclusions are that the involuntary motion of the rod, or the *malaise* which occurs in certain dowsers on approaching the hidden object of their search (whatever that object may be), arise from an obscure nervous reflex and muscular spasm, which is stimulated by suggestion and also by other causes. Among the latter, in a good dowser, may be classed a transcendental perceptive power, not consciously exercised, but able to start a nervous or muscular spasm. Evidence of the existence in certain individuals of such a faculty new to science, goes back to a remote period, and is supported by a considerable amount of trustworthy and recent experimental research, so that its recognition by science may be hoped for in the not distant future. This faculty is one allied to that of *instinct* in animals, inasmuch as it is a case of *nascitur non fit*. Further experiments in dowsing—conducted with the same care as Professor Wertheimer has taken—are greatly to be desired, but it is hopeless to expect any conclusive results without prolonged investigation. Negative evidence in psychical research is of the same value as the negative evidence adduced by those who deny the existence of meteorites because they have never seen one fall.

P.S.—The word "dowsing-rod," I may say, in answer to inquiries, is probably the Celtic-Cornish translation of striking-rod, the colloquial German name of the divining "rod," *duschan rhodl* becoming in time "deusing," and thence "dowsing-rod," and hence our modern "dowser."

Mr. T. W. Danby said that the divining practised by the earliest dowsers was for minerals, whereas the object of the modern dowsers was to find water. Agricola, the well-known authority on mediæval mining, stated that the use of the divining-rod enabled the dowser to find only mineral veins, which was very different from finding pockets of water or ore, or springs of water. A mineral vein had this mysterious characteristic, that there was no record in any mining book of any observer ever having got to the bottom of a mineral vein. Fifty years ago, when he was a student at the Royal School of Mines, he had the

only personal experience in his life of dowsing, and he was very much astonished at the results. During the long vacation he and a fellow-student had the privilege of travelling with the then Professor of Mining, the late Sir Warington Smythe. First of all, they went into North Wales, where, to his astonishment, he found that the miners believed thoroughly in divining. From Wales they went to the Isle of Man, where he was still more astonished to find that dowsing was a positive article of belief. In discussing the subject with some of the mining captains, the suggestion was made that, as his fellow-student and himself knew nothing of the locality, and were profoundly sceptical on the subject, the opportunity should be taken of putting dowsing to a practical test. It was thereupon agreed that his fellow-student and himself should walk along holding a hazel twig, the point of which was upwards, near the old Foxdale silver mines; that a miner should walk by the side of them, and when the divining-rod turned down, the miner should mark the place with his pick. He walked along with the twig, and, to his blank astonishment, it turned down more than once, while his fellow-student's twig also turned down at intervals. The captain of the mine subsequently said that he did not think his fellow-student had been very successful, but his (Mr. Danby's) indications were nearly all correct—in fact that he was an expert diviner!

Mr. S. Simmelkjoer stated that during the meeting of the German Association of Gas and Water Engineers, held in Königsberg in June, 1910, Mr. Bieske read a paper upon the divining-rod, and at the conclusion of an interesting discussion the author made the following remarks: "During the discussion the word 'swindle' has been used several times. I did not use that word, and I do not approve of it, because, in my opinion, in most cases it is more a question of disease than of swindle." That remark was heartily approved by the meeting.

Mr. W. N. Gardner asked whether the author knew of any case where a water diviner had been able to state the quantity of water which would flow from a particular source.

Mr. C. H. J. Clayton inquired whether Professor Wertheimer had any experience of dowsers on clay lands where it was practically impossible to find water.

Professor Wertheimer, in reply, said he did not know of any case where a dowser had been able correctly to determine the quantity of water which was to be derived from the source he had discovered, but there were two machines on the market which professed not only to find where water was present, but also the depth at which it existed. He had written to the persons interested in those machines asking them to perform some tests with them, but so far, for various reasons, they had not found it possible to do so. He had not tried any experiments on clay lands, as he had not deliberately asked a dowser to conduct an experiment that was certain of failure. He had always taken the dowser to a place where there was water for him to discover, so that he might work under the fairest possible conditions. He did not intend to start any technical training for dowsers, although he regretted to say there were, in the West of England, certain gentlemen who took apprentices and professed to teach them the art and mystery of dowsing. With regard to Professor Barrett's criticisms, he did not give the history of the subject in his paper, mainly for the reason that Professor Barrett had given it so very fully himself, his papers covering two whole parts of the Proceedings of the Psychical Research Society. Those papers gave a vast amount of evidence, very little of which, however, was of an experimental character. The kind of evidence given by Professor Barrett was that Mrs. So-and-So stated she knew that a dowser did indicate that water would be found in a certain place, and on a well being sunk water was found there. Personally, he was not concerned in that class of evidence, because he admitted at once that many cases of that sort were undoubted facts. Professor Barrett next stated that the test with running water was an unfair one. He had not taken upon himself to say what was fair and what was unfair; he had gone to dowsers and asked them to lay down what they considered a fair test, and this, it seemed to him, was the scientific way to attack the question. It would be very unfair of him, if a chemist told him that he could do something wonderful in chemistry, to ask the chemist to prove it to him by conducting an experiment in accordance with conditions that he (the author) would lay down. That would not be at all fair; the chemist must be allowed to conduct his experiment in his own way. Therefore, when Mr. Pavey told him that he could discover water in an iron water-pipe, he did not ask himself whether Professor Barrett thought it was fair or not, because Mr. Pavey himself thought it was fair and carried out the test. Then Professor Barrett thought that sufficient care had not been taken to secure the real article to carry out the tests. That was absolutely wrong. Mr. George Roberts, one of the gentlemen of whom Professor Barrett had never heard, was vouched for by no less than six gentlemen of good position in his own neighbourhood; he had worked for a great number of people, and was exceedingly well-known; in fact, there was no doubt he was a professional dowser of considerable ability.

On the motion of the Chairman a vote of thanks was accorded to Professor Wertheimer for his paper, and the meeting then terminated.

HOME INDUSTRIES.

Plague and the Silk Trade.—It seems that the plague has obtained a footing in Chefoo, one of the chief Chinese silk centres. The silks collected there are despatched to Shanghai, either direct or *via* Tsingtan, and thence distributed by the European houses to consumers in America, Europe, India, and Asia Minor. The principal varieties are Shangtung tussore, and Shangtung pongees. It is said that the Chinese silk export trade is being seriously affected by the disorganisation and reduction of transit facilities resulting from the precautions taken to prevent the spread of the plague, and there is considerable delay in the arrival of silk at the ports. It is expected that the next silk crop will show a large decrease.

Sudanese Cotton and the Trade Outlook.—It is reported that several cotton merchants in the Sudan intend to forward all their cotton direct to Liverpool, and already one shipment has been so sent through the Kordofan Commercial Company. The reports as to the present crop are very encouraging. The Economic Board of the Sudan Government gives the following details on the state of the crop:—"In November 35,000 feddans were reported to be under cotton at Tokar. Rains have been good, and a satisfactory crop may be expected. The quality should be even better than last year, as all seed sown has been good Egyptian of one kind. The plants are in the best possible condition. The greater part of the crop is from Mitafifi seed provided by the Government on repayment. Cotton in Berber province, according to reports for November and December, is not coming on so well. Natives are inclined to starve their cotton as regards water. Egyptian cotton was successfully grown as a flood crop in the White Nile province. This is noteworthy, as vast areas of flood land are available in that province. Lack of rain spoilt the cotton at Renk. Cotton as a rain crop is reported fair at Kodok and Melut. Picking was to begin in December. As a general rule, cotton is poor when sown on untilled low ground where rain streams have washed over it, but at Malakal a crop sown very late proved an exception to this. A good crop is expected from Debeloweid." Commenting on the cotton trade outlook, Mr. F. Ashworth, writing to the Manchester Chamber of Commerce, asks:—"Can the consuming world take off a full production at the present comparative high cost?" In his opinion, with the present capacity of production, and given sufficient inducement, it would be quite possible to supply for export from this country, 600 million yards per month (the monthly average in 1910 was 500 million yards) of assorted cotton piece goods (or 7,200 million yards per annum). But our oversea markets are not yet capable of taking up such a supply, even at normal prices, still less at present rates. Mr. Ashworth's conclusion, therefore, is that the preservation of healthy relations between supply and demand does not admit of the machinery, either spindles or looms, being continuously worked at its full capacity throughout the current year, under the prospective conditions governing the trade. There is still too much machinery for the capacity of the markets.

The Growth of Insurance.—The returns just published by the Board of Trade relating to life assurance testify to the continued development in all branches of life assurance. The total amount of life assurance effected with British companies during 1910 exceeded the total recorded for any previous year. As showing the growth in the amounts paid in premiums in connection with ordinary and industrial schemes of assurance, and the increase of funds, the following figures are given:—

	Ordinary Assurance. Premiums.	Ordinary Assurance. Funds.	Industrial Assurance. Premiums.	Industrial Assurance. Funds.
	£	£	£	£
1890...	13,928,001	160,172,605	4,360,438	7,167,869
1895...	16,862,514	188,372,536	5,927,835	11,875,423
1900...	20,829,017	231,339,585	8,078,728	18,392,283
1905...	23,903,788	277,537,214	10,600,611	27,111,038
1909...	29,402,259	336,413,395	14,127,016	42,669,066

The assurances in force at the end of 1909 aggregated £782,198,531 under ordinary tables, in addition to £292,689,157 industrial policies. In 1890 the figures respectively were, £442,436,266 and £85,920,639. The growth in industrial business has been very rapid during the period under review, and the figures point to the growing prosperity of a large section of the community. They also refute the prophecies of those who held that legislation would prove injurious to life assurance business.

The Motor Liner.—Reference was recently made in these Notes to the order in the hands of a Clyde firm for an oil-engined Atlantic liner, but particulars were wanting. It is now known that she will be of 5,000 tons and will carry both passengers and cargo. This is the first serious attempt of British shipbuilders to construct a motor-boat of such large dimensions. A cargo motor-boat of 8,000 tons is being built in a German yard for the Hamburg-America line, and will, it is expected, be ready for service early this year.

Educated Women Workers.—The report of the work done in the first eighteen months of its existence by the Educated Women Workers' Home Training Fund is encouraging. During the period named fifteen women have finished their training, two have entirely paid back their fees, and seven are paying regular instalments. The professions adopted include midwifery, physical culture, lecturers, and teachers of dancing. The Association lends money to girls and women who desire the training necessary for a specified profession, and the question of funds is therefore all important. Much more money is wanted if the Fund is to do all it might do in the way of help to poor gentlewomen, and it ought not to be very difficult to get it, provided the organisation is on a sound business basis.

Piece Goods for Southern Nigeria.—Attention is called to a proposed amendment of the Folded Woven Goods Ordinance of Southern Nigeria by a Bill about to be introduced into the Legislative Council. The Bill permits some variations in the manner of folding certain goods to meet the requirements of the trade, and consolidates the various amendments already made to the original Ordinance. The following new section is quoted:—

No folded goods other than those specified in the schedule thereto shall be imported into the colony or protectorate unless the same shall be folded in folds not less than 36 inches in length and each piece be marked with the number of yards and inches (if any) contained therein. Such mark shall be stamped on the fabric of each piece. Any words, figures, marks, or abbreviations of the words "yards" and "inches" which, according to the common use or custom of the trade are commonly taken to indicate the measure of the folded woven goods, may be used in such marking. No piece shall be made up to show more folds than the full number of yards it actually contains, any portion of a yard (over such number of yards) not to be shown as a fold. The above section is to apply to all folded woven goods imported into the colony or protectorate, whether for sale, use, or disposal therein, or for transhipment to or in transit for any other country, port, or place, but the Comptroller of Customs may, with the approval of the Governor, exempt goods in transit for any other country in which the manner of folding or marking such goods is regulated by law.

The exemptions referred to are those given in the *Board of Trade Journal* on December 1st, 1910.

The Manchester Canal.—Messrs. W. H. Coward, Limited, of Finsbury Pavement, have addressed a letter to the Manchester Ship Canal Company advocating the provision by shipowners of more accommodation for dead-weight cargo in the steamers that already load in the Canal. They write:—

"We take the liberty of addressing you on the subject of a great inconvenience, amounting practically to the negation of the advantage promised as a result of the extension of the sea traffic of Manchester, so far as shippers of dead-weight are concerned. We are considerable exporters to the British colonies of cast-iron pipes, machinery of all kinds, fire-bricks, and goods generally, all of which come under the denomination of dead-weight. We are also, in a smaller degree, shippers of measurement goods from your city. It appears that from the limited draught of steamships necessitated on leaving your port the tonnage offering is not sufficient to carry away the accumulation of cargo, and a large quantity is at present diverted, at an increased cost of carriage, to other ports. This state of things is sufficiently serious, but when we find, and we believe we are correct, that in most cases steamers ascending the Canal are already partly supplied with dead-weight collected at other ports, it produces circumstances absolutely adverse to the prosperity of Manchester as a loading centre. The remedy for this anomalous position naturally appears to be the increase of tonnage, and in order to make up satisfactory general cargoes a due proportion of measurement should also be forthcoming, which the brokers say they cannot obtain."

The letter will no doubt receive the attention of the Manchester Association of Importers and Exporters.

The National Telephone Position.—The report of the National Telephone Company for the first half of the current year has just been issued, and is the last report the Company will issue as a going concern. When it passes under the control of the Postmaster-General it will have been in existence for twenty-four years, and its revenue has now reached a sum approximating to three and a half millions sterling. The percentage of working expenses to net income has been steadily increasing in recent years, and is now over 64 per cent. as compared with 56·32 per cent. in 1896, but its net income is over one million. The Post Office takes over the undertaking on lines similar to those governing tramway transfers; that is to say the plant will be purchased at its fair market value, regard being had to its suitability for the purposes of the Post Office telephone service, but no payment will be made for goodwill or compulsory purchase, and certain powers of objecting to plant as unsuitable are reserved to the Postmaster-General. At the option of the Government, three-fourths of the purchase-money, and with the consent of the Company the whole of it, may be paid by way of annuity for a term not exceeding twenty years. That portion of the purchase-money not paid in cash will take the form of terminable annuities running over the period named, interest on the balance outstanding from time to time being fixed at the rate of 3 per cent. per annum, payable quarterly. The total amount of capital invested in the Company is £11,483,593.

CORRESPONDENCE.

THE TAJ MAHAL, AGRA.

The number of the *Journal* containing Mr. Robert Chisholm's paper on The Taj Mahal, etc., has just reached me in Egypt. I regret that where I am now I have not suitable books of reference at hand, but I should like to point out that the dimensions of some great domed buildings in Europe which Mr. Chisholm gives are far from correct. He tells us that Santa Sofia at Constantinople covers a square of about 130 feet. By this statement he must mean that the dome covers a square of that area. This is by no means the case. The span of the dome, which is the same as that of the square on which it rests is just about 100 feet. "St. Peter's at Rome, about 126 feet." This is not a remarkably clear statement. No doubt he refers to the span of that majestic dome which rests on a square with the corners cut off, and has a diameter of 140 feet or thereabout. "St. Paul's, London, 95 feet." St. Paul's dome covers a square space, although by the arrangement of the great supporting arches it might be supposed to stand over an octagon, and this space is 108 feet across.

SOMERS CLARKE.

Mahamid, Upper Egypt,
January 13th, 1911.

Mr. Robert F. Chisholm, to whom the foregoing letter has been submitted, writes in reply:—

Mr. Somers Clarke, in his note dated January 13th, calling into question my figures of the relative sizes of the areas covered by the well-known domical buildings, Santa Sophia, Constantinople; St. Peter's, Rome; and St. Paul's, London, does not seem to realise the impossibility of any two men agreeing as to how the relative merits of the structural difficulties overcome can be presented by measurement. Even the straightforward measurements are many. There is, first of all, the simple size measured from wall to wall at the floor level; secondly, the size measured in the same way at any point between the floor level and the level of the springing of the dome; thirdly, the length of the side of the greatest square which can be inscribed within the points of support parallel with the main axis of the building; fourthly, the side of the greatest square set diagonally with the main axis; and, fifthly, the diameter of the dome itself—whence arise other considerations. The Byzantine dome (Santa Sophia) resembles half an orange with the four cheeks cut off by vertical lines, leaving four points making a square which rest on the *centres* of the sides of, say, a square box, whereas in St. Peter's the half-orange rests on the *corners* of the box. In St. Paul's these corners are split up into three, so that the dome has twelve supporting props. Further, it is noted that every advance of the corners diminishes the difficulty of the structural problem, and that this cutting off of the corners is itself modified by its form and solidity. I think, as incidental statements having no reference whatever to the paper I was reading (The Taj Mahal), I will let them stand as they are. The main point is that whereas Mr. Somers Clarke places St. Peter's first as a structural achievement, I place Santa Sophia first; and I think the majority of the members of the architectural profession will agree with me.

LINEN AND COTTON UNDERWEAR.

As one of those persons who adopted linen underwear, with satisfactory results, on hearing a paper read on the Linen Industry in Ireland, last year, supported by a medical opinion recommending it, Sir G. Birdwood's remarks on page 359 of your proceedings of the 17th inst. come to me as a shock. It is claimed for linen that it absorbs moisture very rapidly, and dries very rapidly, allowing the skin to breathe, and prevents chills and colds; whereas cotton and wool absorb moisture slowly, dry very slowly, retaining the moisture of the body, become felted, choke the pores, and encourage chills and colds. I always understood that those who could afford it in the East used linen or silk underwear, while cotton was only adopted on account of its cheapness. Perhaps some of your readers can authoritatively determine this difference of opinion and the truth of the matter.

G. E. Jones.

BOOKBINDING.

With reference to Mr. Stephen's interesting paper, and the discussion thereon, I have two remarks to make, as a user of books. In the climate of Madras it is an ordinary thing for the dye to come off a book-cover on to one's hands and one's knees, however lightly it may be handled or rested. The chocolate colour of Chambers's "Mathematical Tables" comes off as a bright red. Books intended for engineers have to go to hot and damp places, a fact which should be borne in mind by publishers. The other point is that wall-crickets, and some other insects, are kept off by certain dyes. I had many books bound when in Madras, especially in two colours, a pink (the reverse side of a red) and a pale green (the reverse side of a dark green). In both cases the side I used shows the threads, and I much prefer it to the side intended to be used. The material, very cheap, is, I believe, cotton, and seems to be sized. If not placed in a shutting-up book-case the pink covers are attacked at once by the wall-crickets, which, slobbering as they feed, make pale patches of a blotchy character, sucking out the size, but not attacking the threads. The green covers, on the contrary, were never attacked even when placed amongst pink books on which the creatures were feeding.

Reginald Ryves.

NOTES ON BOOKS.

The Life-Boat and its Work. By Sir John Cameron Lamb, C.B., C.M.G. London: William Clowes & Sons, Ltd. 1*s.* net.

Readers of the *Journal* will no doubt remember that about a year ago Sir John Cameron Lamb read before the Society a paper, in which he gave a very valuable historical account of the origin and development of the life-boat from the date of its invention in the eighteenth century down to the present time. The subject is one with which Sir John is peculiarly well fitted to deal, as he has long been connected with the Royal National Life-Boat Institution, and is now its Deputy Chairman. As Chairman of the Council of the Royal Society of Arts, he was also much interested in the part played by the Society in the early development of the life-boat: and he relates how, in 1802, it awarded a gold medal and fifty guineas to Henry Greathead; in 1807 a gold medal to Christopher Wilson; in 1810 a silver medal and twenty guineas to the Rev. J. Bremner; in 1814 a silver medal and ten guineas to Thomas Boyce; and in 1817 a silver medal to Captain Gabriel Ray. These rewards were all granted for inventions in connection with life-boats, and if, as Sir John Lamb says, it is difficult to restrain a smile at the details of two of them, the fact of their award shows that the Society—true to its pioneer principles—was alive at a very early period to the importance of encouraging research in this direction.

It is, perhaps, hardly necessary to describe in detail the contents of the book, as they are the same in substance as the paper which appeared in the *Journal* of February 18th, 1910. A number of excellent illustrations have been added, not the least interesting of which is a reproduction of the wreck-chart of the British Isles for 1907–8—a most convincing argument for the cause which Sir John Lamb advocates. The little book gives an extremely interesting and complete account of the subject with which it deals, and it is to be hoped that it will enjoy a wide circulation, the more especially as any profits derived from its sale will be handed over to that most deserving of bodies, the Royal National Life-Boat Institution.

GENERAL NOTES.

International Art Congress at Rome.—Arrangements have been made to hold an International Art Congress in connection with the Exhibition of Fine Art which will be opened at Rome on March 27th next. The Congress will last for eight days. The subjects to be discussed have been divided into five groups: (1) Problems connected with culture and teaching; (2) the teaching of art; (3) æsthetics and public art; (4) exhibitions, competitions, legislation; (5) study and experiment in technical processes. A large and influential International Patronage Committee has been formed, under the presidency of the Minister of Public Instruction.

Indian Oyster Culture. — The American Consul at Calcutta states that an article on Indian oysters in the Madras Fisheries Bulletin has drawn attention to the commercial possibilities of oyster culture in India, for although there are numerous natural oyster-beds in various parts of India, there is no organised oyster industry anywhere. Some years ago the oyster-beds of Sindh were exceedingly prolific, and made Karachi famous. To-day the supply is totally insufficient, and the beds practically wrecked. In most of the estuaries of the Madras Presidency edible oysters are found. The shape of the Indian oyster seems to be determined by the character of its habitation. In muddy creeks and channels they are long and narrow, and in sandy beds of water they assume a broad form An ideal oyster-bed has been discovered in the Pulicat Lake, but the most extensive beds in Southern India are those in Cochin Harbour. Early precautionary measures should, it is said, be taken to safeguard all existing beds, and their cultivation developed by the introduction of experts.

The Silk Industry in Italy.—The importance of the Italian silk industry may be seen from the following figures taken from a Ministerial report recently issued.

The number of silk manufactories throughout the country are 2,413, employing a total of 232,549 hands, of whom 20,307 are males and 212,242 are females. Their wages amount annually to seventy-five million of lire (three million pounds sterling).

Amongst European nations, Italy still holds her position as the largest silk producer, but during the last twenty years she has lost the supremacy she then held, and now occupies only the third place, as will be seen from the following statistics:—

	1890–91.	1909–10.
China . .	4,910,000 kilos.	7,480,000 kilos.
Japan . .	2,018,000 „	8,672,000 „
Italy . .	4,590,000 „	4,251,000 „
France . .	650,000 „	674,000 „

The Egyptian Cotton Industry. — A recent Khedivial decree has authorised the creation of a Department of Agriculture in Egypt, and the appointment of a Director-General to that office. Although no definite plans have yet been formed as to the work of the new administration, it is believed that it will have to do principally with the control of cotton culture, and by systematic surveillance to prevent over-irrigation of the cotton fields by native growers, who in the past have retarded the maturity of the plants by flooding the fields too frequently. The education of the native farmer as to the proper kinds of seeds to use and as to the best crop rotations will, it is believed, also claim much of the attention of the new department. The Director-General is now visiting the cotton-producing districts with a view to gathering first-hand knowledge of the actual conditions that he will be called upon to supervise. The Egyptian Government is experimenting on its Korashieh Estates with a new cotton-seed styled "Assili," which has produced approximately 800 pounds per acre. It is like "Afifi" in colour, but better in quality, and is expected to fetch about eight shillings and fourpence more per hundredweight than any other variety cultivated in Egypt. The Ministry of Agriculture at Constantinople has asked the Ottoman High Commissioner in Cairo to send a quantity of Egyptian cotton-seed of the best varieties with a view to being tried in Turkey.

Chinese Pottery in the Straits Settlements.—Chinese are pioneers in the art of pottery. They use few implements, and the rapidity with which they fashion pots is marvellous, especially some of the Straits Settlements potters. The potter's wheel is the essential part of the workman's equipment. This is a large flat disc of stone revolving on a pivot. When the clay is properly prepared, a five-pound piece, which is sufficient for a ten-inch pot, is cut off, rolled into a ball, dabbed with burnt rice husks, and placed on the disc. The workman's left hand is gently thrust into the centre of the clay, while his right hand is slightly pressing on the outside to keep the whole together; but it is from the inside that most of the shaping is done. Meanwhile the wheel is made to turn more quickly. Then by keeping both hands

opposite each other—*i.e.*, one inside and one outside—together moving slowly up from the wheel, pressure by both hands is exerted, and the shapeless mass of clay assumes the shape of a pot with astonishing rapidity. A thin piece of wood is used to flatten the rim, and usually the same piece is used to measure the pot to see if it is the correct size. A potter will mould two ten-inch pots in three minutes. These newly-made pots are set in the sun for one day, and then placed in an oven arrangement, where they are "fired," an operation which takes four days.

Traffic on the Simplon Railway.—Since the opening of the Simplon Tunnel in the spring of 1906, both the passenger and goods traffic by this route show a marked increase, as will be seen by the following returns:—

	No. of Passengers.	Goods.
1906	260,000	26,000 tons.
1907	365,000	75,000 ,,
1908	375,000	81,000 ,,
1909	376,000	102,000 ,,
1910	497,000	135,000 ,,

The Production of Sparkling Burgundy in France.—In making sparkling Burgundy, the best qualities of wines are carefully selected and kept in cool cellars, to be prepared to the taste of its consumers. The fining and racking require the greatest attention. The wine is then bottled and piled in a cellar having a steady temperature of 50° Fahrenheit, where the fermentation takes place. The American Consular Agent at Dijon says that under normal conditions fermentation takes two years. When the ferment has destroyed the original substances, which prevented limpidity and good conservation, the carbonic acid gas, created by the decomposition of the natural sugar, produces the final and complete clarification, and the wine has received the maximum of its hygienic quality. When fermentation is finished, and the sediment precipitated, the bottles are placed on an inclined table, necks downward, and gently moved every day for sixty days, so as to bring the sediment to the corks. The corks are then removed, and the sediment forced out by the gas in the bottles. The operation must be carried out as quickly as possible to avoid loss of wine. The bottles, after being refilled and recorked with new corks, are put back in the cellar, and are ready for labelling and shipping.

Alcohol from the Carob Bean.—The discovery that alcohol can be extracted from the fruit of the carob tree has caused this article to be looked upon as much more valuable than formerly. This tree is a leguminous evergreen found in Spain, Italy, and the Levant, and its fruit, commonly called the carob bean, is about one inch wide and from six to eight inches long, and when dried has hitherto been used as food for animals. Experiments have lately been made in Spain to obtain alcohol from this bean. After triturating the fruit it was immediately placed in hot water to steep, and the sugar or glucose extracted by means of a current of water. The liquid resulting from this process was then allowed to ferment, the glucose thus being transformed into alcohol, which was later distilled. It was found that 2·3 quarts of pure alcohol could be obtained from twenty-two pounds of the beans. A factory has been established at Faro, in Portugal, furnished with a triturator of 4,000 pounds' capacity per hour. Here the practice is to steep the beans in four or five times their weight of water. The quantity of water depends upon the amount of glucose contained in the beans, which must be determined chemically. The distilling is carried on with the most modern apparatus, because the alcohol from the carob bean, unless very pure, emits a peculiar odour and has a disagreeable taste. Owing to the great quantity of carob trees (*algarrobo*) in Spain, this discovery will probably establish another important industry there, as well as in other Mediterranean countries. Large quantities of the bean are grown in the neighbourhood of Barcelona; and in the provinces of Valencia and Castellon, and in the south, the production is even greater.

United States Coal Production.—According to reports received by the United States Geological Survey from coal-mine owners and others familiar with the industry, the production of coal in the United States during 1910 was between 475 and 485 million short tons, a considerable increase over the output of 460 million short tons in 1909, and approximately within one per cent. of the maximum previous record of 480 million tons produced in 1907. Of the total production in 1910, the anthracite mines of Pennsylvania contributed nearly 83 million short tons, and the bituminous mines between 390 and 400 million tons.

Coco-nut Oil Butter in Austria.—A new substitute for butter has been placed on the market in Western Bohemia. It contains no animal fats, but is manufactured from coco-nut oil, the yolk of eggs, and a small proportion of cream. The coco-nuts are imported by the shipload by way of Hamburg, up the Elbe to Aussig, where the factory is situated. The meat of the coco-nuts is pressed for the oil, the outer fibrous shell is used in the manufacture of mats, and the hard shell is made into buttons. Coco-nut oil has been used for some time in Europe in the manufacture of oleomargarine under various names, but in combination with lard or other animal fats. The "vegetable" butter is prepared in two forms—soft and in firm cakes. It is shipped by parcels post from the factory in packages of five kilogrammes (eleven pounds). The claim is made that this butter substitute has an agreeable flavour, is not injurious to health, and is excellent for cooking purposes.

The Mangrove Bark Industry in Australia.—A company has been formed in Sydney for utilising mangrove bark to meet commercial

demands for tanning and dyeing purposes, and, according to the American Vice-Consul in that city, a concession has been obtained from the Government of Queensland for taking the bark from trees on land near the coast of North Queensland, between Cooktown and Cape York. It is said that the supplies of black mangrove trees in the northern part of Australia are almost unlimited, the forests being found along rivers, creeks, and estuaries near the coast, frequently on mud flats, which are inundated at high tides. Many of the trees grow large, and permit of poles fifty feet long being cut, while from a single tree upwards of a ton of bark has been stripped. Previous attempts to make commercial use of Australian mangrove bark have not met with success, owing to the high freight in shipping the bark to countries equipped with plant suitable for treating the bark, but the present plan contemplates conveying the bark to a factory near the trees, where it can be dried and crushed, and the cutch made into solid extracts, which can be more easily exported. It is estimated that 240 tons of bark will produce 45 per cent. of cutch. It is said that Queensland is in a position to compete, under favourable conditions, with the principal sources of mangrove supplies, that is to say, the east coast of Africa, North Borneo, etc.

THE PRODUCTION OF TUNA CHEESE IN MEXICO.—The tuna cheese industry has been of importance in Mexico from time immemorial, and San Luis Potosi has long been the great tuna market of that country. The tuna plant grows spontaneously in San Luis Potosi, Guanajuato, and Zacatecas, on land too dry at present to permit of much other vegetation. In some parts of San Luis Potosi it grows in such profusion as to render fair returns to landowners, in spite of the exceedingly low price realised for the fruit. The cheese is made by simply boiling and straining the tuna pulp until the proper consistency is reached. It is of a chocolate colour, pleasant to the taste, wholesome, and slightly laxative. Sometimes nuts or flavours are added, and the product is said to be better when taken with milk. The leaves of the tuna plant, which is of the prickly pear family, are used for fodder or dried and used for fuel. The term "tuna cheese" is descriptive only of the consistency of the product; it is, rather, a confection, and is to be sold in the United States, to which country it is being exported from Mexico in small packages as a confection.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MARCH 1.—LEONARD E. HILL, M.B., F.R.S., "Caisson Sickness and Compressed Air."

MARCH 8.—JAMES CANTLIE, M.A., M.B., C.M., D.P.H., "Plague and its Dissemination." Sir SHIRLEY FORSTER MURPHY, M.R.C.S., will preside.

Wednesday afternoon, at 4.30 o'clock:—

MARCH 15.—Colonel CHARLES EDWARD CASSAL, V.D., F.I.C., "The Adulteration of Food." The Right Hon. the Lord Mayor of London will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MARCH 16.—CLAUDE HAMILTON ARCHER HILL, I.C.S., C.S.I., C.I.E., "Education in India." The Right Hon. Lord NORTHCOTE, G.C.M.G., G.C.I.E., C.B., will preside.

APRIL 27.—Sir THOMAS HENRY HOLLAND, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord AVEBURY, D.C.L., LL.D., F.R.S., will preside.

MAY 25.—W. R. H. MERK, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

FEBRUARY 28.—The Hon. Sir RICHARD SOLOMON, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., High Commissioner for the Union of South Africa, "The Resources and Problems of the Union of South Africa." The Right Hon. LEWIS HARCOURT, M.P., Secretary of State for the Colonies, will preside.

APRIL 4.—Captain R. MUIRHEAD COLLINS, C.M.G., "Australia and her Resources."

MAY 9.—F. WILLIAMS TAYLOR, "Canadian Banking."

CANTOR LECTURES.

Monday Evenings, at 8 o'clock:—

Professor ADRIAN J. BROWN, M.Sc., "Brewing and Modern Science." Four Lectures.

Syllabus.

LECTURE IV.—FEBRUARY 27.—"The Fermentation Process." Previous Treatment of the subject by Dr. G. Salamon in 1888—The Pure Yeast Question in Brewing—Zymase and Modern Views of Alcoholic Fermentation—Nitrogen Assimilation—The so-called "secondary" products of Fermentation, etc.—Conclusion.

Professor J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

Syllabus.

LECTURE I.—MARCH 6.—"The Laws of Electric Heating, Radiation, and Thermometry." The Transformation of Electric Current Energy into Heat—Joule's Law—Explanation on the Electronic Hypothesis—Necessary Qualities of the Conductor and Conditions for the Production of High Temperature—Laws of Radiation—Stefan-Boltzmann Law—Wien's Displacement Law—The Electrical Measurement of Temperature—Resistance Thermometry—Thermoelectric and Radiation Pyrometry.

LECTURE II.—MARCH 13.—"The Appliances and Processes of Electric Heating." Resistance and Arc Heating—Direct and Inductive Methods—Electric Furnaces of Girod, Heroult, Kjellin, Keller, Stassano, Ferranti, Rodenhauser, and others—Resistance Furnaces for Chemical Operations, both at Moderate and Very High Temperatures—Experimental Models.

LECTURE III.—MARCH 20.—"The Technical Applications of Electric Heating." The Manufacture of Graphite, Carborundum, Calcium Carbide, Quartz Glass, Aluminium, Ferro-Alloys, and Iron and Steel in Electric Furnaces—Electric Welding—Electric Furnaces for Metallurgical and Chemical Operations.

LECTURE IV.—MARCH 27.—"The Domestic Applications of Electric Heating." Electric Water Heating—Its Cost and Economy—Air Heating by Electric Radiators and Convectors—Electric Cooking—Various Systems and Types of Utensil critically discussed—The Advantages and Drawbacks in Comparison with other Methods of Culinary Heating.

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

Dates to be hereafter announced:—

FRANK M. ANDREWS, "Architecture in America."

ARTHUR CHARLES DAVIS, F.C.S., Assoc.Inst.C.E., "The Manufacture and Testing of Portland Cement."

GEORGE B. HEMING, "Art Education in Jewellery and Goldsmithing." Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., will preside.

Professor RAOUL PICTET, "Les Basses Températures."

Sir WILLIAM ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

HAL WILLIAMS, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

NOEL HEATON, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 27...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor Adrian J. Brown, "Brewing and Modern Science." (Lecture IV.)

Geographical, Burlington-gardens, W., 8.30 p.m. Dr. W. T. Grenfell, "Labrador."

Actuaries, Staple Inn Hall, Holborn, W.C., 5 p.m.

TUESDAY, FEBRUARY 28...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) The Hon. Sir Richard Solomon, High Commissioner for the Union of South Africa, "The Resources and Problems of the Union of South Africa."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. A. E. H. Tutton, "Crystalline Structure: Mineral, Chemical and Liquid." (Lecture I.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. A. T. Blackall, "Modern Railway-Signalling: Some Developments upon the Great Western Railway."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. E. W. Harvey Piper, "Lordly Lincoln."

Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. F. Simpson, "Thermometry in its Application to the Carriage and Storage of Refrigerated Produce."

WEDNESDAY, MARCH 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. Leonard Hill, "Caisson Sickness and Compressed Air."

Public Analysts, Burlington House, W., 8 p.m. 1. Annual General Meeting. 2. Messrs. R. Ross, J. Race, and F. Maudsley, "Examination of the Process of Shrewsbury & Knapp for the Estimation of Coco-nut Oil." 3. Dr. A. C. Cumming and Mr. A. Gemmell, "The Estimation of Iron by Permanganate in the Presence of Hydrochloric Acid." 4. Dr. A. Backe, "The Analysis of Sweetened Condensed Milk." 5. Mr. H. S. Shrewsbury, "Note on Henry C. Frey's Method of Estimating Petroleum in Turpentine." 6. Mr. J. P. Batey, "Note on the Formation of Hypoiodites and their Action on Sodium Thiosulphate—A source of error in certain Iodine Titrations." 7. Dr. C. B. Savory will show a new form of Specific Gravity Apparatus.

United Service Institution, Whitehall, S.W., 3 p.m. Major-General H. T. Arbuthnot, "The Crimea Revisited."

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. H. H. E. Craster, "The Abandonment of the Roman Wall."

West India Committee, 15, Seething-lane, E.C., 3.45 p.m. Mr. W. Fawcett, "Some Interesting Features of Tropical Vegetation in the West Indies."

THURSDAY, MARCH 2... Royal, Burlington House, W., 4.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Dr. Malcolm Burr, "Dermaptera (Earwigs) preserved in Amber, from Prussia." 2. Miss Laura Roscoe Thornely, "Report on the Marine Polyzoa of the Collection made by Mr. J. Stanley Gardiner in the Indian Ocean in H.M.S. 'Sealark.'" 3. Mr. W. M. Tattersall, "On the Mysidacea and Euphausiacea collected in the Indian Ocean during 1905."

Roentgen Society, 19, Hanover-square, W., 8.15 p.m.

Chemical, Burlington House, W., 8.30 p.m. 1. Mr. S. U. Pickering, "Potassium Cupricarbonates." 2. Messrs. M. O. Forster and A. Zimmerli, "Studies in the Camphane Series. Part XXIX. A New Phenylhydrazone of Camphorquinone." 3. Messrs. A. Hopwood and C. Weizmann, "Synthesis of Dipeptides of Lauric Acid with Glycine, Alanine, Valine, Leucine, and Asparagine." 4. Messrs. F. G. Pope and H. Howard, "Fluorone Derivatives." 5. Messrs. F. B. Power and A. H. Salway, "The Constituents of Witharia Somnifera."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. C. Benson, "Ruskin." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. C. Davenport, "Illuminated Manuscripts."

Philatelic, 4, Southampton-row, W.C., 6 p.m. Mr. F. J. Peplow, "Display of the 1871–6 Issues of Japan on Entires, with Notes on the Cancellations."

FRIDAY, MARCH 3... Royal Institution, Albemarle-street, W., 9 p.m. Dr. F. A. Dixey, "Scents of Butterflies."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. H. Ellis Hill, Jun., "Lagos Harbour Survey, 1909–1910."

SATURDAY, MARCH 4...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Radiant Energy and Matter." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,041. VOL. LIX.

FRIDAY, MARCH 3, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 6th, 8 p.m. (Cantor Lecture.) Professor J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." (Lecture I.)

WEDNESDAY, MARCH 8th, 8 p.m. (Ordinary Meeting.) JAMES CANTLIE, M.A., M.B., C.M., D.P.H., "Plague and Its Dissemination." Sir SHIRLEY FORSTER MURPHY, M.R.C.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES ON "BREWING."

On Monday Evening, February 27th, Professor ADRIAN J. BROWN, M.Sc., delivered the fourth and last lecture of his course on "Brewing and Modern Science."

On the motion of the Chairman, a vote of thanks was accorded to Professor BROWN for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

TUESDAY AFTERNOON, FEBRUARY 28th, the Right Hon. LEWIS HARCOURT, M.P., Secretary of State for the Colonies, in the chair. A paper on "The Resources and Problems of the Union of South Africa" was read by the Hon. Sir RICHARD SOLOMON, K.C.B., K.C.M.G., K.C.V.O., K.C., High Commissioner for the Union of South Africa.

The paper and discussion will be published in a subsequent number of the *Journal*.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s*. 6*d*. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

TWELFTH ORDINARY MEETING.

Wednesday, March 1st, 1911; ERNEST WILLIAM MOIR, M.Inst.C.E., in the chair.

The following candidates were proposed for election as members of the Society:—

Curtis, Miss Gertrude M., 5, Victoria-street, S.W.

Hayward, Johnson, Tuesley Lane Cottage, Godalming, Surrey.

Hebdon, William, 56, Tresillian-road, St. John's, S.E.

Johnston, Edward Hamilton, I.C.S., Terlings, Harlow, Essex.

Willott, Frederic John, The Aluminium Corporation, Limited, Wallsend-on-Tyne.

The following candidates were balloted for and duly elected members of the Society:—

Bell, Thomas, Messrs. John Brown & Co., Ltd., Clydebank, Scotland.

Byrne, James, 24, Broad-st., New York City, U.S.A.

Cookson, Clive, Oakwood, Wylam, Northumberland.

Dubilier, William, 431, Lumber Exchange Building, Seattle, Washington, U.S.A.

Lee, Harold, 56, Oxford-street; and Fairfield, Broughton Park, Manchester.

Lello, Thomas Stanley, High-road, Chadwell Heath, Essex.

Mackay, Robert John, Secretary's Office, General Post Office, E.C.

Mansell, Walter H., 405, Oxford-street, W.

Pitt, T. E. Sandford, Calne, Wilts.

Srivastava, Jwala Prasad, B.Sc., Municipal School of Technology, Manchester.

Sunderland, John Samuel, 37, Aberdeen-road, Highbury Park, N.

Todd, John, Hamilton House, 155, Bishopsgate, E.C.

The paper read was—

CAISSON SICKNESS AND COMPRESSED AIR.

By Leonard Hill, M.B., F.R.S.

Attention was first called to caisson disease or compressed-air sickness in the middle of last century, when Triger applied the use of compressed-air caissons to the sinking of coal shafts through the wet soil at Chalons on the banks of the Loire. Hoppe Seyler (1857) and Thos. Schwann (1858) in Germany, and Bucquoy (1861) in France, gave the first correct suggestion as to the cause, viz., that it was due to the setting free of bubbles of gas in the blood. Nitrogen gas is dissolved, according to the law of partial pressures, during exposure to the compressed air, and this dissolved gas having no time to escape through the lungs, if the pressure be suddenly lowered, bubbles off just as carbonic acid escapes from aerated water when a bottle is uncorked.

The voice of these men was as that of the prophet in the wilderness; the large majority of medical writers, ignorant of physical laws, held that exposure to compressed air mechanically alters the distribution of the blood, forcing it inwards and causing a congestion of the viscera, which is suddenly and dangerously altered on decompression.

In 1879 Paul Bert published his great work "La Pression Barométrique," in which he described an admirably-contrived series of experiments on animals which proved, once and for all, (1) that the mechanical effects of compressed air are negligible; (2) that during exposure to 8 to 9 atmospheres there is no ill effect until the partial pressure of oxygen dissolved in the blood reaches such a point that it acts as a tissue poison; (3) that pathological accidents occur only after decompression, and are due to bubbles of nitrogen appearing in the blood and interfering with the circulation; (4) that these effects can be prevented by making the rate of decompression slow enough.

After Bert's death, Philippon and others in France confirmed his work, but in England, and particularly in America where many great caisson works were initiated, engineers remained in ignorance of Bert's great work, and the mechanical theory held sway. In Germany von Schrötter, Heller and Mager published in 1900 a valuable work, in which they collected all the data then available. They established the clinical picture of compressed-air illness, and explained in full its protean nature, and showed how this depends on the ischæmia produced by bubbles interfering with the circulation in one or other part of the body. In particular they demonstrated that the paralysis, so often produced (diver's palsy), is due to a local death and degeneration of the spinal cord, produced by bubbles blocking the circulation there. They laid down the principle that a uniform decompression at the rate of two minutes per 0·1 atmosphere was safe, basing their calculations on a law of saturation and desaturation of the body, which had been enunciated by Zuntz (1897). Two years earlier, in 1898, I began the experimental study of this subject in England, and by my experiments independently established the truth of Bert's conclusions and overthrew the mechanical doctrines which were generally held here and America. For the last fifteen years I have continued researches on the subject, and I now propose to give you the chief results of these. Before doing so I may state that in 1899 Lorrain Smith greatly advanced our knowledge of oxygen poisoning by showing that very long exposure (for two days or so) to a partial pressure of 75 per cent. to 100 per cent. of an atmosphere produces a fatal inflammation of the lung, while short exposures to over 2 to 3 atmospheres of oxygen quickly produces the same effect (180 per cent. of an atmosphere in twenty-four hours, 300 per cent. in five hours). E. W. Moir reported that mules lived for a year in the Hudson Tunnel, where the partial pressure of oxygen was about 60 per cent. of an atmosphere. They remained in perfect health.

In 1907 Vernon made a very important contribution by showing that oil or fat exposed to air takes up in solution over five times the volume of nitrogen and oxygen that water does. In the same year Haldane, with Boycott and Damant, for the Admiralty Committee on deep-water diving, made an equally important contribution, in which they showed (1) that the deep-water diver hitherto had not been given a sufficient air supply and had in consequence suffered from excess of carbon dioxide. (2) That the legs of his dress required lacing up to prevent his being blown up helpless from the bottom by too big an air supply. (3) That the saturation of the body in compressed air was much slower than generally thought. (4) That safety lay in making the exposure a short one for deep-water work (previously insisted on by Catsaras). (5) That it is safe to decompress rapidly from the maximum absolute pressure to half this pressure, the second stage of decompression being made slow enough to allow the

supersaturated blood to give up the nitrogen to the lungs.

After this brief introduction I will now give an account of the chief experiments I have carried out with the help of first one and then another colleague—J. J. R. Macleod, C. E. Ham, M. Greenwood, F. Twort, and H. B. Walker.

Disproof of Mechanical Theory.—(1) I enclosed a frog's heart in a small chamber with thick glass windows, and showed that it continued to contract in a normal manner at a pressure of even 50 atmospheres. Similarly I showed that a frog's muscle could be excited to contract normally in like conditions. (2) In caterpillars, air is conveyed directly to the body cells by finely branching tracheae. Their circulating liquid is not respiratory in function. Sudden decompression from 27 atmospheres had no ill-effect on these, unless they had eaten leaves while under pressure. Then they were burst by the swelling of the swallowed bubbles (Greenwood). (3) I enclosed a narcotised dog or cat in a pressure chamber, having first connected its carotid artery with a mercurial manometer, and set the manometer recording on a clockwork drum, the manometer and drum both being put inside the chamber. I showed that the blood pressure and pulse beats exhibited no noteworthy change on raising or lowering the pressure 2 to 3 atmospheres (confirmation of Bert). (4) I contrived a chamber with glass windows, in which I placed a frog so that the web of its feet might be illuminated with an arc light and projected microscopically on to a screen. I found that the circulation in the capillaries did not alter when the pressure was raised quickly or lowered 20 atmospheres and even 70 atmospheres.

Proofs that Nitrogen Bubbles are the Cause of the Illness.—(1) By the same means I demonstrated both the setting free of nitrogen bubbles in the blood on decompression, and the fact that they can be again driven into solution by recompression — for on suddenly decompressing after a long exposure I had the keen pleasure of seeing the bubbles appear in the capillaries, grow in size and stop the circulation, to shrink and disappear again on putting up the pressure (*Proceedings of the Royal Society*, vol. lxx., p. 454, 1902). This experiment was repeated by Sir Thomas Oliver (*Journal of the Royal Society of Arts*, May 11th, 1906, vol. liv.). (2) Macleod and I enclosed narcotised dogs in a pressure chamber, having first connected the carotid artery to a tap so that we could draw off samples of blood into a vacuum pump and analyse the blood gases. We then confirmed Bert's observations, and showed that the nitrogen dissolved in the blood varies with the partial pressure, roughly 1 per cent. of nitrogen is dissolved per atmosphere. By the same method we studied the giving-off of nitrogen from the lungs during decompression. (3) C. Ham and I killed rats by rapid decompression from 10 atmospheres, and chopped up their bodies under water, collecting the gas set free in their bodies under a funnel full of water. We found 80 to 90 per cent. of the gas was nitrogen, and the rest chiefly carbon dioxide with a trace of oxygen, *e.g.*, 10·7 to 16 per cent. CO_2, 2·1 to 4 per cent. O, 87·2 to 80 per cent. N. The gas obtained was more than there ought to have been according to the law of partial pressures and the volume of water in the body. This excess we found was partly due to gas, swallowed or set free by fermentation, in the alimentary canal. Part of the excess, no doubt, was due to the greater solubility of nitrogen in fat, a fact then undiscovered. (4) We killed mammals by rapid decompression, and, opening the right side of the heart under water, analysed the gas obtained and showed it was 80 to 90 per cent N, the rest being carbon dioxide with only a trace of oxygen. The carbonic acid escapes from the blood because the nitrogen set free acts as a vacuum in regard to CO_2. The oxygen chemically unites with and is used up by the blood, and therefore is only found in small amount (confirmatory of von Schrötter). (5) Greenwood and I showed that rats and frogs, if submitted to high pressures of oxygen *until poisoned* by it, and then rapidly decompressed, have considerable amounts of dissolved oxygen set free in their bodies. This never occurs with low pressures of air, and oxygen bubbles are not a factor in caisson sickness. (6) We also showed that animals killed by decompression in 3 to 5 seconds from + 7 to 8 atmospheres have gas bubbles in the fat droplets of the tissue cells, such as the liver and kidney, which actually vacuolise and disrupt the structure of the tissue cells. The liver and kidney may appear foamy with bubbles in such case. The fat, too, in all cases of rapid decompression, is honeycombed with bubbles, like whisked white of egg. Alveoli of the lungs, too, may be ruptured and lobules rendered emphysematous by the violent expansion of the air within them. Much gas is set free in the alimentary canal, and in small animals, as the rat, within the peritoneal cavity. The blood

vessels are filled with columns of bubbles. Such a distribution of gas may be found in men killed by bursting of caissons. (7) Comparing big rats with small rats, pregnant with virgin rats, and mice with rats, we found the danger of rapid decompression increases with body weight. An herbivorous animal, the guinea-pig, too, is more susceptible than a kitten of the same weight. A. Smith found the heavier and older men more susceptible at the Brooklyn Works.

Boycott and Damant have since shown that the risk varies as the fatness of the animal. This we have recently found to hold good with pigs. Fat pigs weighing 100 to 120 lbs. are more susceptible than smaller pigs of 50 to 60 lbs. The bubbles once set free in the fat of pigs may stay there for days after decompression, as we have found to our cost, for it has seriously damaged the sale of the animals to the butcher, since the fat does not bleed properly and remains pink.

Vernon showed that fat exposed to 1 atmosphere dissolves about five times the amount that water does. F. Twort and I have shown that this holds good up to 7 atmospheres.

The following are the figures we obtained:—

50 c.c. olive oil (specific gravity ·917) were shaken at +95 lbs. for 38 minutes, and allowed to stand at +95 lbs. for 2½ hours. Room temperature, 17·3° C. The gases were then extracted from a sample.

Volume of gases (N.T.P.).	Calculated on Vernon's results.
N 35·55	39·21
O 18	17
CO_2 1·62	1·491

Time spent in collecting sample, 1 minute. Pressure fell 2½ lbs. during collection. The rest of the oil was left for three day sat +92 lbs., falling to +84·5 lbs. The sample gave:—

Volume of gases (N.T.P.).	Calculated on Vernon's results.
N 33·61	35·53
O 15·56	15·4
CO_2 1·55	1·35

The oil gave a slow evolution of visible bubbles after reduction of the pressure in 10 minutes from + 90 to + 20 lbs., even without any oscillation of the chamber. All the results give further proof that fat men should be excluded from caisson work. The varying percentage of fat in the blood, chyle, liver, must be an important factor in the evolution of bubbles in the blood of compressed-air workers. The less fat in the food eaten in the caisson the better.

Oxygen Poisoning.—(1) I showed that all kinds of animals, worms, snails, flies, spiders, frogs, etc., are instantly convulsed and killed by exposure to 50 atmospheres oxygen. (2) The frog's heart beats, nerve conducts and muscle contracts for some time in 50 atmospheres O, but there is evidence of progressive diminution in functional power, the muscle behaving like a fatigued muscle. The central nervous system is, as Bert showed, the first point of attack of high pressures of oxygen. (3) Mice exposed to 10 atmospheres O are thrown into tetanic spasm, and on being decompressed continue to be convulsed by a touch. Bubbles of oxygen are to be then found in the central nervous system compressing the nerve cells. As the bubbles are oxygen the cells do not die and the animals may recover, the oxygen being absorbed by the tissues and the circulation re-established. (4) + 3 atmospheres O convulsed animals in 30 to 60 minutes (so Bert and Lorrain Smith), and the poisonous effect, depending as it does on the partial pressure of O in the blood, comes on just as soon in larger animals as in small, *e.g.*, cats, rats, and mice. (5) Fatal inflammation of the lung is produced by exposure to high partial pressures of oxygen, *e.g.*, after 25 hours continuous exposure to + 7 atmospheres of air = 170 per cent. of an atmosphere O (confirmation of Lorrain Smith). This can be prevented by using nitrogen to dilute the air, and so lowering the partial pressure of oxygen. (6) It is quite safe to breathe 1 atmosphere oxygen, or 5 atmospheres air, for 3 to 4 hours. The men who wear the Fleuss apparatus for rescue work in mines have breathed it day after day for this period. I have spent much time in perfecting this apparatus on physiological lines, and so have studied particularly the effect of oxygen on man. In very hard work there may be a deficiency of the oxygen supply in the body, and then breathing oxygen helps the working power of the man.

If the body is getting enough oxygen the breathing of it has no effect on the metabolism. The resting man cannot be fanned into a greater rate of activity by breathing oxygen. Poisonous pressures of oxygen lower the metabolism and diminish the carbonic acid output of animals. M. Flack and I showed that the breathing of oxygen just before a race may help an athlete, because during his great effort he uses up oxygen quicker than his respiration and circulation can provide it. A shortage of oxygen leads to the production of acid products in the tissues and blood, which causes breathlessness and stiffness of the muscles (Ryffel).

Carbon Dioxide and Temperature of Air in Caissons.—Much has been made of CO_2 as a contributory cause of caisson disease. Mr. E. W. Moir, the distinguished engineer, one who has the greatest practical knowledge of compressed-air work, has drawn particular attention to this. M. Greenwood and I have exposed ourselves to compressed air and allowed the partial pressure of CO_2 to rise to 1·8 per cent. of an atmosphere, without any inconvenience. We have exposed cats and dogs to as much as 4 per cent. CO_2 without untoward results, beyond increased frequency of respiration. Recently I have carried out many experiments on students sealed up in a small air-tight chamber, and found that it is the heat, moisture and stillness of the air which cause discomfort and fatigue, and not the excess of CO_2, or deficiency of oxygen in the air breathed. The putting on of powerful electric fans by whirling the air and cooling the body gives very great relief, even when there is 4 to 5 per cent. of CO_2 in the chamber (confirmatory of Haldane's work).

Hot, moist, still air causes fatigue by taxing the cooling mechanism of the body; blood is sent to the skin to be cooled which ought to be going to muscle and brain; a higher blood-pressure has to be maintained to effect this, and this fatigues the heart. Fatigue increases the danger of decompression by making the circulation and respiration less efficient. The heat causes more blood to come to the skin and a more complete saturation with nitrogen there. The cold in the decompression chamber—due to expansion of the air—causes vaso-constriction and repels the blood from the skin and so stops its desaturation. We have lost pigs by taking them from the warm caisson into the cold air.

Over hot and moist—that is, under-ventilated—caissons have, therefore, a higher morbidity. The wet-bulb temperature must be kept below 75° F., and if possible well below 70° F. (Haldane). The men should not pass from a warm caisson to a cold air-lock and a cold outside world. They should go through a warm lock to a warm room.

Hot moist atmospheres are very disadvantageous to health and work. If the wet-bulb temperature is high in the caisson, the current of air should be increased or electric fans used to cool the workers. Electric fans have enormously increased the efficiency and health of Europeans in the tropics. (2) An excess of CO_2 in the air-lock, or diver's helmet, during decompression is favourable, as it increases the pulmonary ventilation and the outbreathing of nitrogen. Haldane advises the air-pump to be slackened purposely. There is no harm in breathing 0·5 to 1 or even 2 per cent. of an atmosphere of CO_2. (3) The diver requires, as Haldane showed, one, two, three, and even four pumps to maintain an adequate ventilation in his helmet as he goes deeper. If there is four times as much air compressed in his helmet he must have four times as much air pumped through to wash out the CO_2 and prevent him becoming breathless with excess. The working of three or four pumps means many men and much labour. I have suggested in place of many pumps the use of a chamber containing caustic soda carried on the back of the diver, and an injector on the inlet of the helmet, so arranged as to suck the air in the helmet through the caustic soda and absorb the CO_2. Messrs. Siebe, Gorman & Co. have made the first trials of this suggestion. One pump with this device should be enough for deep work.

R. H. Davis, of the above firm, and I have contrived also a self-contained diving-dress fitted with cylinders containing 50 per cent. oxygen, and a caustic soda chamber. The oxygen supply lasts an hour, and the same injector plan is used in this dress to purify the air. A telephone wire, but no life-line or air-pipe is carried, and this makes the dress suitable for exploration of flooded mines, tunnels, etc. By using 50 per cent. oxygen there is no risk of oxygen-poisoning if the dress is used at depths not exceeding seventy to eighty feet (Haldane). It would, I think, be safe to use it at 100 feet for half an hour.

Recompression as a Cure.—Macleod and I found that we could restore animals on the point of death, after too rapid a decompression, by quickly recompressing them to the former pressure. Dangerous cases brooked no delay, for the vital parts cannot stand interruption of the circulation for more than a very few minutes. On the frog's web I observed how the bubbles shrink up on recompression and expand again on decompression.

F. Twort and I have observed microscopically, and measured bubbles set free in water or oil, after decompression from + 90 lbs. On recompression the bubbles shrink and the volume, calculated from the diameter, varies inversely as the pressure, following Boyle's law. The surface tension of the skin of the bubble has no noteworthy disturbing effect. The bubbles appear as small ones, about 0·1 to

0·2 mm.; they form round dust particles and roughnesses of the wall, and run together to form larger ones. On recompression, some of these bubbles persist when the pressure is raised again to +90 lbs., and enlarge again on lowering the pressure. This shows why, after recompression of a case of caisson sickness, the decompression must be made very slowly.

A. Smith suggested the use of a medical lock or recompression chamber at Brooklyn. In the first French caissons it had been noted that the men went back into the caissons to get relief from bends.

E. W. Moir instituted the medical lock in all the works in his charge, brought it into prominence, and by its means has effected great saving of life and suffering. Some of the cases he has kindly reported to me have been in truth of men raised from the dead.

For deep-diving work I contrived with Messrs. Siebe, Gorman & Co. a decompression chamber. This consists of a double-chambered diving-bell, one chamber (A) open at the bottom to the sea, the other (B) closed save for a manhole communicating with (A). The bell is lowered to the bottom, and the divers, after completing their work, enter (A), and from thence pass into (B) and close the manhole. The bell is then raised on deck and (B) is slowly decompressed. A recompression chamber ought to be on hand in all important deep-sea diving works. The men engaged in caisson works—run at dangerous pressures—should have barracks at the works, and remain there after the shift so that they may be at once recompressed on first sign of illness. The onset of illness is often delayed even for an hour or more, for it depends on the accumulation of bubbles and stoppage of the circulation in some vital part.

In experiments on pigs we have several times lost the animals on their way home to the farm, after we had, as we thought, safely decompressed them. We have failed to cure pigs, dangerously affected, by recompression, when the interval has been more than a very few minutes.

Direct Effects of High Pressures.—As all our experiments showed that dogs, cats and monkeys could be safely decompressed at a rate of 20 minutes per atmosphere from +100 lbs., M. Greenwood and I went under pressure ourselves. A suitable chamber was supplied us by Messrs. Siebe, Gorman & Co., who have helped us in every way and most generously. We owe a special debt of gratitude to Mr. R. H. Davis, the managing director. We used a steel boiler (volume 42·2 cubic ft.) fitted with a telephone. In this one or other of us were exposed on eleven occasions to pressures above +60 lbs., four times to +75 lbs. (M. Greenwood once went to + 92 lbs.). We were actually exposed to above + 60 lbs. for half an hour, and were virtually exposed for nearly an hour if we take into account the time of compression, which was slow. We were safely decompressed by the uniform method (about 20 minutes per atmosphere), only on two occasions suffering from minor local symptoms. From + 92 lbs. M. Greenwood was decompressed in 2 hours 17 minutes. Damant and Catto have since dived to the corresponding depth in the sea, and have been decompressed safely by the stage method. We found there is no sense of pressure, *e.g.*, it is not possible to tell + 3 from + 5 atmospheres. The voice becomes very high pitched and nasal in quality, whispering and whistling impossible.

The respiration is normally regulated by the partial pressure of carbonic acid in the alveoli of the lungs, on which depends the concentration of acid in the blood passing through the respiratory centre in the brain. Normally the partial pressure of CO_2 equals about 5 per cent. of an atmosphere. We found this held good up to + 75 lbs. pressure.

Percentage of CO_2 found on analysis of alveolar air of lung.	Pressure in lbs.	Percentage found multiplied by pressure in atmospheres.
5·3	+ 0	5·3
0·9	+ 75	5·4
1·0	+ 60	5·0
1·8	+ 30	5·4
2·7	+ 15	5·4
5·4	+ 0	5·4

We collected and analysed our alveolar air while in the caisson, and it was rather astonishing to observe the percentage of CO_2 fall as the pressure rose from 5·4 at 1 atmosphere to 0·9 at 6 atmospheres.

Methods of Decompression.—Saturation of the body with nitrogen depends on the relation between the circulating blood volume (the velocity with which the volume circulates) and the mass of the absorbing tissue fluid. The shorter time it takes for the blood to go round the body, the greater is the volume of the blood circulated per minute through the lungs and tissues. During saturation the blood carries the nitrogen from the lungs to the tissues; during desaturation it carries it from the tissues to the lungs. The rate of the circulation varies

in different organs, and so the saturation time varies. There are parts quickly and parts slowly saturated. The fat absorbs five times as much as the watery tissue, and therefore takes much longer to saturate and desaturate (Vernon).

The brain and spinal cord have much fat in the myelin of the nerve sheath. But as the brain has a more active circulation than the spinal cord, the white matter of the spinal cord is a commoner seat of bubbling, which leads to ischaemia, degeneration of the tissue, and paralysis.

According to Haldane, the whole body is about half saturated in half an hour, and about saturated in 4 hours. Bornstein thinks 6 to 7 hours are required for saturation of the fat. Bodily work, by increasing the circulation and pulmonary ventilation six times, or more, enormously reduces the time of saturation. Warm, moist caissons, by dilating the skin vessels and increasing perspiration, accelerate the circulation in the periphery, and make the saturation there far more rapid than in a man exposed to cool wind. The diver is surrounded by cold water. the caisson workman by warm, moist air. The latter generally works much harder and longer hours, and therefore suffers far more from "bends." The diver goes to much greater pressure for short times, and after quick decompression may suffer from asphyxia or paralysis—from bubbles in the heart or spinal cord.

Greenwood and I studied on ourselves the saturation of a quick part—the kidney. When the kidney is actively secreting, the saturation of the urine must approximate to that in the arterial blood.

One of us drank two pints of water, and half an hour later was raised to + 45 lbs. He then emptied his bladder, and ten minutes later emptied it again. The urine filled a glass receiver, which was sealed, and the gases were extracted from it afterwards with the gas-pump. By this device samples of urine actually secreted in definite intervals, after a given pressure limit had been reached, were available for analysis. The results showed us that the kidney—in a state of activity—is about saturated in 10 minutes.

We were decompressed at a rate of 20 minutes per atmosphere, and our urine showed that desaturation lagged behind the fall in pressure. Our urine still contained an excess of gas at the end of decompression.

It is assumed that the blood is saturated, or desaturated, each time it passes through the lungs. The Admiralty tables of stage decompression are based on this assumption.

Figures which F. Twort, H. B. Walker, and I have obtained make it doubtful whether this is so. We breathed oxygen for 35 minutes and until there was only 10 per cent. nitrogen left in the alveolar air of the lungs, and collected the urine *secreted then*. The amount of nitrogen dissolved under 1 atmosphere of air at body temperature is reckoned to be 0·825 per cent. (Bohr). We actually found 0·878 per cent., using the Buckmaster and Gardner gas-pump, which gives the least possible source of error. After breathing the oxygen, we found 0·257 per cent., and on another occasion 0·316 per cent. We should expect to find, with a partial pressure of only 10 per cent. atmosphere N, about 0·11 per cent. Either this extra nitrogen came from the kidneys, they having retained it, or else from the arterial blood.

The same lag is found in decompression experiments, and, considering the freedom of the diuresis, it is doubtful whether the kidneys can have retained all the excess of nitrogen, and it seems highly probable that the blood does not desaturate completely during its passage through the lungs.

In dealing with this problem, the following came into consideration:—

The two kidneys contain about 170 grm. of tissue water and perhaps 20 grm. of fat. As the fat has five times the saturation power for nitrogen, the solvent power of the kidneys would be equivalent to about 270 grm. of water. About 100 grm. of urine is passed each time, and a great volume of blood is circulating through the organs.

Time.	Pressure in lbs.	Per cent. N. in Urine.	Per cent. N. calculated.
4. 0	+ 45	3·93*	3·47
4. 6 – 4.12	Decompressed to 13	—	—
4.13	+ 13	3·7	1·62
4.22	+ 13	2·62	1·62
4.28	+ 13	2·30	1·62
4.34	+ 13	1·87	1·62
4.43	+ 13	1·80	1·62
4.45 – 4.52	Decompressed to 0	—	—
4.55	+ 0	1·64	0·825
5. 0	+ 0	1·28	0·825

On decompressing a resting animal, the nitrogen should be given up by diffusion from the lungs in the same time as that required for saturation. Now the viscosity of the blood

* The error of analysis makes the readings too high by 0·2 to 0·3.

prevents the formation of bubbles under a certain strain; hence it is safe for a man to be rapidly decompressed after exposure to about + 18 lbs. (general experience of caissons).

It is safe, therefore, to come rapidly from 30 to 15 lbs. (absolute), or half-way. Since the volume of a gas is halved at 2 atmospheres, made one-fourth at 4 atmospheres, one-eighth at 8 atmospheres, and the volume of a bubble is doubled on lowering the pressure from 8 to 4, 6 to 3, 4 to 2, or 2 to 1, Haldane concluded it was safe to come rapidly from 4 to 2, 6 to 3, or 8 to 4 atmospheres. The supersaturated tissues then give nitrogen to the blood, and the blood to the lungs, and the nitrogen escapes without bubbling at the half-pressure stage, where a long pause is given.

This stage method of decompression is of great value to divers, who only go down for a short period and do not work very hard, for it prevents the saturation of slow parts. The men are decompressed from the dangerous pressure to one half of it before the slow parts (fat, etc.) are saturated.

Caisson workers work hard and for long shifts, which means they are practically saturated. The Admiralty Committee, by experiments on goats, found a great superiority of the stage over the uniform method of 20 minutes per atmosphere, and established detailed tables of decompression on the strength of these experiments. These tables are drawn up, and give times of decompression with a great appearance of exactitude. They are based on theoretical assumptions as to the circulation time, volume of blood, desaturation of the blood in its passage through the lungs. As bodily activity has a most potent effect on the circulation, increasing the rate perhaps six or ten times, and converting "slow" parts into "quick" parts, it seems clear that the tables have only a limited accuracy. As I have pointed out above, the fact that the blood is desaturated in its passage through the lung requires proof.

Goats, moreover, are not the best animals for comparing with man, because of their chewing the cud, which leads to the swallowing of much air, and this, coupled with production of gas by fermentation, leads often to great distension of their viscera on decompression. We have lost several goats from this cause.

Greenwood and I chose, for investigation, pigs, which are more like men in shape, diet, and habit. We found no pronounced superiority of the stage over the uniform method. The pressure was + 75 lbs., the time of decompression 90 to 110 minutes, the same as that used in the Admiralty Committee's goat experiments. There were 4 fatal or dangerous cases in 20 uniform, 9 in 32 stages, and 9 in 44 modified uniform, decompression rate slowing in proportion as pressure falls.

Using a longer period, we have found it fairly safe to decompress pigs or goats by a one-stage method from + 75 lbs. The method was + 75 to + 18 lbs. in 10 minutes, and + 18 to + 0 lbs. in 20 minutes, after an interval of 80 to 100 minutes. One death and no severe case resulted in 47 pigs weighing 50 to 100 lbs., 1 severe and 3 slight cases in 19 goats weighing 39 to 57 lbs.

Similar decompression of fat pigs from + 90 lbs., allowing an interval of 105 to 120 minutes at + 18 lbs., gave unfavourable results—7 deaths and 1 severe case in 27 pigs. These pigs weighed 81 to 115 lbs., and the fact that they were very fat and never moved during decompression told greatly against them.

Only one pig out of all showed any symptoms after being decompressed in 10 minutes to the stage at + 18 to 20 lbs. It is therefore safe to use the stage method for a man; the only question to settle is the duration of the stage and the handling of the second part of the decompression.

Bornstein has compared the stage and the uniform method at the Elbe Tunnel Works (+ 2 atmospheres).

Days.		Workers	Cases of Illness.	Illness per Day.
20	Stage	526	15	0·94 ? 0·75
16	Uniform	528	17	1·21 ? 1·06
18	Stage	529	12	0·67
16	Uniform	529	14	0·88
14	Stage	536	12	0·86

The figures show a slight advantage for the stage method, but it is within the limits of error, for the number of cases from time to time vary widely in caisson works. Bornstein has got much better results by making the men climb a ladder 25 metres high immediately after decompression, so as to excite the circulation and pulmonary ventilation.

No Climbing after Decompression.

Days.	Workers.	Cases of Illness.	Illness per Day calculated on Basis of 1000 Workers.
31	527	56	3·37
33	529	43	2·13
13	536	17	2·26

CLIMBING AFTER DECOMPRESSION.

Days.	Workers.	Cases of Illness.	Illness per Day calculated on Basis of 1,000 Workers.
24	407	4	0·39
27	338	17	1·80
13	328	4	0·87
13	162	4	1·79
12	112	1	0·59

In this respect I note that Mr. Francis Fox states that when he visited the St. Louis Works (57½ lbs.), he found the morbidity greatly lessened by the substitution of lifts for climbing after decompression.

I do not think violent exercise would be wise *after* too short a decompression from a high pressure. Making our pigs struggle has several times brought on symptoms. The exercise should be given during the stage interval.

8,500 man shifts were decompressed by Japp at the East River Tunnel, New York, by a stage method—from + 40 lbs. in 48 minutes. There were 1·62 per cent. cases and no serious ones. The method used was—(1) + 40 to + 29 lbs. in 5 minutes; (2) 10 minutes' walking in + 29 lbs.; (3) + 29 to + 12½ lbs. in 8 minutes; (4) 10 minutes' walking in + 12½ lbs.; (5) + 12½ to + 0 in 15 minutes. Lengths of tunnel were arranged between locks for walking in. The Admiralty table ordains 92 minutes for this pressure. Half this time, evidently, is enough, and no doubt less if the men were made to do hard muscular exercise during the stages.

Bornstein calculates the same volume of nitrogen expelled by uniform decompression in 1 minute would be expelled by stage decompression in 0·5 to 0·6 minutes.

Breathing oxygen	—	0·35 min.
Forced breathing	0·5 to 0·9	,,
Light bodily work	0·2 to 0·25	,,
Heavy ,, ,,	0·1 to 0·2	,,

Greenwood and I, in the experiments on ourselves, realised the importance of muscular work, and by exercising ourselves were decompressed safely from pressures which have proved dangerous for fat, somnolent pigs. We in vain tried to make the pigs exercise by giving them electric shocks. I have no doubt that the best method to shorten decompression safely is to make the men work during decompression. They should be made to climb at the half-pressure stage.

Breathing Oxygen to Hasten Decompression.—F. Twort, H. B. Walker, and I have investigated this by the urine method. We have breathed oxygen during uniform and stage decompression, and observed its effect by analysis of the nitrogen gas in the samples of urine collected every 7 minutes.

Oxygen helps to clear the nitrogen out, as this experiment shows:—

Time.	Pressure in lbs.	Per cent. N. in Urine.	Per cent. N. calculated.
12.50	45	3·83	3·47
12.53 – 12.57	Decompression to 30	—	—
12.57 – 1. 1	Decompression to 15. Breathed oxygen for 2 min.	—	—
1. 2	15	3·22	1·70
1. 4 – 1. 7	Breathed oxygen	—	—
1. 9	15	2·13	1·70
1.10 – 1.15	Decompression to 10. Breathed oxygen for 3 min. Oxygen supply then gave out.	—	—
1.16	10	1·63	1·42
1.23	10	1·45	—
1.30	10	1·76	—
1.32 – 1.39	Decompression to 5	—	—
1.37	5	1·61	1·12
1.40 – 1.44	Decompression to 0	1·35	0·825

Bornstein has breathed oxygen (90 to 95 per cent.) for 48 minutes (at + 2 atmospheres), and two engineers at the Elbe Tunnel breathed it for 30 minutes. These important observations show the limit to which such high partial pressures of oxygen can be breathed safely by man. Bornstein has found the time limit given above must not be overstepped. He freed himself from "bends," after 8 hour exposures to + 2 atmospheres, by using oxygen.

The oxygen can be breathed economically by the use of the Fleuss apparatus,* which was used so effectively in the last great colliery disaster at Bolton. This apparatus can be put on in the works and oxygen breathed for 10 minutes before and again during decompression. This, coupled with active exercise to excite the circulation, ought to clear out most of the nitrogen in a very few minutes. For every atmosphere the body dissolves nitrogen to about 1 per cent. of its mass—for a 70 kilogramme man, say, 700 c.c. per atmosphere. Von Schrötter calculates that oxygen plus muscular exercise would turn out 1,000 c.c. in 5 minutes, probably more. We are at present investigating this interesting point.

Oxygen is now made from liquid-air plant, and it ought to be feasible to put up a plant in important

* I have invented a simple oxygen generator and inhaler, by means of which a bag of oxygen can be made by the action of water on oxylithe ($NO_2 O_3$). This could be used easily in a caisson.

works, and use oxygen in the air-locks for deep work *under expert medical advice.* By using oxygen, and exercise in the air-locks, work might be done at a depth considered now to be dangerous.

Length of Shift.—It is generally held that length of shift increases risk (E. W. Moir, Bornstein). Bornstein says he can be decompressed from + 2 atmospheres in 20 seconds after 50 minutes exposure, while he suffers from "bends" after 8 hours exposure if decompressed in 20 minutes per atmosphere. Bends, no doubt, are due to saturation of the peripheral "slow" parts. Bornstein says a much slower rate is needed for 8 hours than for 1 to 2 hours or 2 to 4 hours shift. To prevent bends, no doubt this is the case, but I doubt whether there is evidence that dangerous cases are much more frequent with 6 to 8 than with 3 to 4-hour shifts. The question of saturation is complicated by that of fatigue: a long shift fatigues the circulatory mechanism and makes it inefficient during decompression.

Neither the tables of the goat experiments of Boycott, Damant, and Haldane, nor the tables of Keays concerning the 557,000 man-shifts at the East River Tunnels, give conclusive evidence that shifts of 3 hours are more dangerous than 1½, or 8 than 3.

The variations in percentage of cases, even when calculated from groups of 3,000 to 4,000 man-shifts, are very large, *e.g.*, 8-hours shift 0·43 per cent. May, 1907, and 0·94 per cent. January, 1907. Chance plays a very big *rôle.* The first 3-hours shift gave 0·35 per cent. cases, and 9 fatal or dangerous in about 43,600 man-shifts; the second 3-hours shift (after 3 hours interval) gave 0·72 per cent. cases, and 4 dangerous or fatal, in the same number of man-shifts. The sum of cases for the six hours is 1·07 per cent. The percentage in 10,700 man-shifts of 8 hours is 0·62. Two 3-hour shifts with a 3-hours interval appears, then, to be almost doubly as risky as one 8-hours shift, because it doubles decompressions. The percentage of illness was 0·66, of death 0·0035, in 557,000 man-shifts, with a decompression rate of 15 minutes from + 29 to + 33 lbs.

As bubbles persist for a long time, and may act as starting-points for the formation of other bubbles, it is wise to give long intervals of time between successive shifts in deep-water work. Bubbles have been seen in veins of animals killed 48 hours after decompression (Bert, Haldane). They last for days in the spinal cord (Boycott and Damant), and in the subcutaneous fat of pigs.

Recompression of the Greatest Value.—Of the above 3,692 cases among 10,000 men, 89 per cent. were bends, 5 per cent. vertigo = 95 per cent. non-dangerous; 1·26 per cent. pain and prostration, 2·16 per cent. paralysis, 1·62 per cent. dyspnœa, 0·46 per cent. collapse = about 5 per cent. dangerous.

Recompression in the medical lock relieved 90 per cent., and of the rest all but 0·5 per cent. were partly relieved. Oxygen breathing could be used with great effect in the medical lock, and it ought to be always at hand there. Down Bros. make for me a small face-mask, by which the gas can be administered efficiently from a cylinder of compressed oxygen. The ordinary way of giving it to patients through an open funnel or nozzle is most inefficient.

Von Schrötter has suggested breathing hydrogen or marsh gas to dilute the oxygen and wash out the nitrogen—a dangerous mixture to use, and I cannot see how it will help, for these inert gases will be dissolved and take the place of the nitrogen.

Recompression is no good if delayed too long. Nerve cells, cut off from the bloodstream for a few minutes, cannot be recovered. Therefore the men should live close to the medical lock.

Fat in the Food.—The following observations made by F. Twort and myself show how water behaves when reduced from + 90 to + 20 lbs., and either left quiet or gently shaken.

WATER SHAKEN FOR 30 MINUTES AT + 90 LBS.

Dissolved Air found.	Dissolved Air at + 90 lbs. calculated.	Dissolved Air at + 20 lbs. calculated.	When collected.
15·1	15·71	—	at + 90 lbs.
14·9	15·28	—	at + 90 lbs.
14·42	15·88	5·26	at + 20 lbs.
9·26	15·28	5·06	after 2 hours at + 20 lbs.
9·78	15·74	5·16	after 2 hours at + 20 lbs.
8·26	16·35	5·41	after oscillation for 15′ at + 20 lbs.
10·47	15·73	5·21	after oscillation for 5′ at + 20 lbs.
6·07	16·19	5·36	after oscillation for 30′ at + 20 lbs.

On gentle oscillation the gas is given off without bubbling. Bubbles only occurred when the water was roughly shaken. This shows how stage decompression is safe as far as regards the watery part of the blood. Oil, on the other hand, bubbles when left quite at rest. It is probable that the fat in the blood, liver, etc., starts the bubbling, and fat eaten increases the

amount of this. Flatulence should be avoided. We lost six goats on one occasion—decompressed from +90 to +20, after a big meal of vegetables. They had chewed the cud at +90 lbs., and died from gaseous distension of the stomach.

Conclusion.—The practical conclusion of the above review is that while decompression times at caisson works are often too short, those tabled by the Admiralty Committee are unnecessarily long. Particularly is this so if the men be persuaded to exercise their bodies during decompression. While the evidence of the superiority of the stage over uniform method is not so marked as the Admiralty Committee maintained, I find a stage method can be made fairly safe, and is the best one to use for caissons.

I think that a stage at + 8 lbs. lasting 15 minutes is enough after a shift at + 30 lbs., and a stage of 30 minutes at + 15 lbs. after a shift at + 40 to 45 lbs., provided a medical lock for recompression is at hand. Five minutes in the first, and 10 minutes in the second case, should be given for completing the decompression. Von Schrötter recommends for +1 to 1½ atmospheres a shift of 6 to 8 hours and decompression in 10 minutes, quicker at first; for + 2 atmospheres a shift of 6 to 8 hours decompression to + 0·8 atmospheres in 3 minutes, and then to + 0 at rate of 4 minutes per 0·1 atmosphere; for + 3 atmospheres a 3 to 4-hours shift and decompression to +1·5 atmospheres in 3 minutes, and then to + 0 at rate of 4 minutes per 0·1 atmosphere. If the men can be arranged to climb from top to bottom of the shaft during the stage it will greatly increase their safety. The breathing of oxygen from a Fleuss apparatus for five minutes immediately before decompression would act in the same way, and, if this were combined with exercise at the stage, the time of decompression might be safely shortened. By how much, further experiment will show. Fat and the older heavy-built men must be excluded, and all men with a defective circulation or pulmonary ventilation. A preliminary trial of "green" men at short shifts is perhaps advisable (Keays). It ought to diminish the tendency to bubble formation if fat food were avoided by caisson workmen, and the diet limited to lean meat, bread and potatoes.

DISCUSSION.

Mr. E. H. Tabor, in opening the discussion, said that any engineer practically engaged in carrying out works in which the use of compressed air was necessary must feel greatly indebted to the author and those associated with him for the valuable researches they had conducted. The only point to which he wished to allude was the beneficial influence of exercise during decompression. As all engineers knew, it was very difficult to arrange in practical work that the men who were being decompressed should exercise while in the air-lock, which was universally a very small chamber where there was not much room to do any work. Moreover, when the men had done their spell of work in the caisson, they did not want to do any more when they got into the air-lock. Some time ago the author informed him that Mr. Bornstein had found it was beneficial if the men did work after they came out from the compressed-air chamber. He thereupon tried the experiment in some works with which he was connected, and the result proved that a good deal was to be said for the system. Figures given by engineers were not comparable with those given by scientists, as it was difficult in practical engineering work to obtain comparable conditions, but the following results were obtained, which he thought were of great interest. Among the men who did not do work after they came out of the air-lock and had been decompressed, there were thirty-seven slight cases of illness in seven weeks. When the men were made to climb a staircase or ladder about sixty feet high after being decompressed, there were only nine cases of slight illness in four weeks. During the first period there was one case of illness in every ninety-four decompressions, and in the second period only one case in every 240 decompressions; and, as far as he was aware, the other conditions were not more favourable during the first period than they were during the second.

Mr. Leon Gaster inquired how many hours the author thought it was advisable that a man should work under compressed air. Special records were kept in Holland of the number of accidents that occurred during compressed-air work, and he was given to understand that two and a half times as many accidents took place when the men were working eight hours at a stretch as when they worked for two periods of four hours, with an eight hours rest in between. It would also be of interest to know what medical supervision was employed for the purpose of selecting men for compressed-air work, and what medical supervision was employed during the actual work.

The Chairman (Mr. E. W. Moir) said that for the past twenty years he had been associated with compressed-air work, and quite recently in connection with the four tunnels made under the East River he was called upon to advise the Bureau of Labour of New York State in reference to the hours of labour, and the general conditions he suggested should be adopted for compressed-air working. The recommendations he made were contained in the appendix to his remarks. Those recommendations were not adopted, but eventually a rough

combination of what he suggested and what the working-men's union desired was put into practice. It was not a very scientific arrangement, but it was a vast improvement on anything that had previously been adopted. Twenty years ago, when he first went out to America in connection with compressed-air undertakings, the death-rate was 25 per cent. per annum of the men employed during the construction of the works, and having his own life to look after, he did all he could to ameliorate the conditions. From the experience he obtained in the erection of the Forth Bridge, prior to that time, on the effect of recompression on the men there employed, he conceived the idea that, whatever might be the cause, recompression was certainly the cure of the trouble. Accordingly, he built the first recompression lock, and he was greatly surprised at the markedly beneficial results which were obtained. His old chief at the time, Mr. Pearson (now Lord Cowdray), was paralysed when he came out of the Hudson Tunnel, in which he had been for two and a half hours, and he was cured of his paralysis within thirty-five minutes by recompression and very slow decompression. He had known a man cured of paralysis twice within five hours. Engineers owed a deep debt of gratitude to the author and his associates for the tremendous amount of unselfish work they had put into their experiments. Engineers had fumbled along, and had arrived at certain conclusions in a rough-hewn kind of way, one of which, with regard to the effect of stage decompression, conflicted, he was sorry to say, with the author's view. It had always been found that if the workmen passed through two or three air-locks, the benefits were very great from a health point of view; why, he did not know. Engineers always put in another diaphragm, if possible, and had at least two air-locks working, as a result of which it was always found there were fewer cases of caisson disease. Prior, therefore, to Dr. Haldane's theoretic discovery, engineers had recognised the benefits of stage decompression, although they did not know the cause. The first diaphragm of the old Hudson Tunnel was so leaky that a second had to be constructed, and that was the first occasion on which two diaphragms were put in operation. It was forced upon their notice that more cases of bends occurred when only one air-lock was in use than when there were two. Whenever possible, more than one air-lock was now built; and recently in the East River Tunnels, where work was being done up to a pressure of 40 lbs. per square inch, which was decidedly a deadly limit, there was not a single serious case of caisson disease experienced. The men took forty-eight minutes to get out, passing through three locks, including two periods of ten minutes of exercise so strongly advocated by the author. Prior to that, with only one lock at a less pressure, several deaths occurred. If decompression was continuously going on, it was difficult to arrange for exercise, but if the men were decompressed in stages it was automatic. If a man had to walk a thousand feet in order to get out, he must perform a certain amount of exercise. The more intelligent men generally worked their muscles and arms in the air-locks, and there was no doubt that that exercise tended to eliminate the bubbles of gas, which were the cause of the trouble. Personally, he did not agree with the author's opinion that carbonic acid had no serious effect. He knew of a case where, after a caisson had been sunk and finally closed in at the bottom with concrete, without any caisson disease occurring, trouble had developed in a few days, and, in fact, seven deaths occurred out of eight men, although precisely the same pressure was used, the only difference being that the air-compressors were run very much more slowly, because there was not leakage and the air-locks were not working. Whether the CO_2 allowed the nitrogen to get into the more delicate parts of the anatomy, or whether by being more easily absorbed, and therefore more rapidly given out, it produced the first block in the system he could not say; but he was confident, as it was only a matter of pounds, shillings and pence to get down the CO_2, it was much better to keep it low. Possibly it was merely an index of something else which caused the trouble. The most interesting details given in the paper proved that if caterpillars could only be trained, they were the ideal caisson-workers, and that pigs were not; and the fact that the author survived the terribly high pressures to which he subjected himself in the course of his experiments proved that he was not a pig. In conclusion, it gave him the greatest possible pleasure to propose a cordial vote of thanks to Dr. Hill for his most valuable paper.

The resolution of thanks was then put and carried unanimously.

Dr. Leonard Hill, in reply, stated that the questions asked by Mr. Gaster were fully answered in a portion of the paper which he had been unable to read owing to the limitations of time. In reply to the Chairman's remarks with regard to CO_2, he thought that no evidence had yet been obtained as to whether the trouble was caused by CO_2, or by heat. If the ventilation was diminished, worse results were obtained; and bad ventilation not only meant more CO_2 but an entire alteration in the cooling of the body. The Chairman contended that it was the CO_2 which did the damage, while personally he thought it was the over-heating and the cooling of the body; and the question in dispute could only be determined by exact experimental observation. With regard to stage decompression, it would be found at the end of the paper that the method he recommended was the stage method. The only thing he objected to was the rather exaggerated way in which that method was regarded by the Admiralty Committee. While he did not think it was so infinitely better, he agreed that the stage method, plus exercise, and plus, if possible, oxygen, was the best method of all.

APPENDIX TO THE CHAIRMAN'S REMARKS.

RECOMMENDATIONS MADE TO THE COMMISSIONER OF LABOUR FOR NEW YORK STATE IN REGARD TO REGULATIONS AND NECESSARY PRECAUTIONS TO BE TAKEN TO ENSURE THE SAFETY AND HEALTH OF EMPLOYEES WORKING IN COMPRESSED AIR.

Hours of Labour.

Eight-hour shifts at the tunnel face in up to 32 lbs. per square inch gauge pressure, with half an hour off for a meal about mid-time, outside in the open-air, if only one diaphragm and one lock; if there be two diaphragms, the meal to be taken between locks, where the pressure will be about half-face pressure.

Above 32 lbs. per square inch gauge pressure, 6 hours in 24 hours in two 3-hour shifts at face, with 2 to 3 hours between working time outside in the ordinary air, in a dry warmed house.

Above 42 lbs. gauge pressure, 2 shifts of 2 hours each at face with 2 to 4 hours' spell between in the ordinary air, in a dry warmed house.

Every man to be medically examined and passed before entry, and periodically thereafter, and also after prolonged absence from work.

Men are to be held answerable if they neglect to carry out rules.

Hot coffee is to be supplied to men at each exit.

Warmed drying-rooms and washing up rooms to be provided for all compressed-air workers.

A recompression medical lock to be provided on all works where the maximum pressure is above 20 lbs. per square inch gauge pressure.

Duration of Decompression.

Gauge Pressure. (Per square inch.)	For One Diaphragm and Lock.		For Two Diaphragms and Two Locks. (For pressures over 25 lbs. per square inch.)
15 lbs.	1 to 3 minutes.		With five minutes between diaphragms at about half maximum gauge pressure.
20 "	3 to 4 "		
25 "	6 to 8 "		3 to 4 minutes.
30 "	12 to 15 "		6 to 8 "
35 "	15 to 20 "	With 10 minutes between locks.	8 to 10 "
40 "	25 to 30 "		12 to 15 "
45 "	35 to 40 "	With 15 to 20 minutes between each lock if 2, and 10 to 15 minutes if 3 locks.	18 to 22 "

RULES ADOPTED AND MADE LAW IN THE STATE OF NEW YORK.

The New York State Legislature have brought forward an Act, signed by the Governor, and taking effect January 1st, 1910, controlling the hours of labours and rates of decompression.

The hours of labour are regulated as per the following table:—

Gauge Pressure (in lbs.).	Time under Pressure.	Interval between Spells.	Uniform Decompression. (minutes.)
0–28	8 hours less interval	30 consecutive minutes spent in the open air	18⅔
28-35·99	2 spells of 3 hours each	At least 1 hour	24
36-41·99	2 spells of 2 hours each	At least 2 hours	42
42-45·99	2 spells of 1½ hours each	At least 3 hours	46
46-49·99	2 spells of 1 hour each	4 hours	50

and no employee shall be permitted to work in pressures exceeding 50 lbs. per square inch, except in cases of emergency.

The decompression shall be at the rate of 3 lbs. every 2 minutes, unless the pressure shall be over 36 lbs., in which event the decompression shall be at the rate of 1 lb. per minute.

EXPERIMENTS WITH BLOOD.

Some rough but interesting experiments were made on animal blood with the following results:—

1. A syphon bottle with a gauge attached was partly filled with bullock's blood, and filled with compressed air at 36 lbs. gauge pressure, and was rotated for 24 hours under this pressure. The pressure was suddenly released, and no visible bubbles showed themselves. Upon closing the valve, however, and letting the syphon stand an hour, a gauge pressure of 1 lb. to the square inch was registered, and at the end of 6 days a pressure of 13 lbs. on the square inch was recorded, showing:—

First, that saturation may never have risen to the full pressure, and

Second, that desaturation progressed very slowly indeed, and much more slowly than it is supposed to do in the body.

2. The vessel was again charged with compressed air up to 100 lbs. pressure, and the entire vessel was then kept rotating slowly for a period of 14 hours. At the end of this time the valve was opened, remaining open 5 minutes, and all the air let out of the vessel without any apparent foaming or surging of the blood. Upon closing the valve and allowing the vessel to stand undisturbed, a continuous decompression was observed, ranging over a period of 3 weeks, indicated by a rise of pressure in the syphon. At the

end of the first week the gauge showed a pressure of 12½ lbs.; at the end of the second week the pressure stood at 25 lbs.; and at the end of the third week the pressure had risen to 31 lbs., where it remained, showing that after the first rapid decompression a slow decompression of the air contained in the blood had taken place until the pressure reached approximately one-third of the original pressure imposed on this vessel. Just what this final pressure would be would, of course, depend on the amount of blood saturated and the amount of space above for the air to expand into.

From my own experience and that of many of my staff, I am confident that after continued daily entering a chamber under compressed air, the blood does not desaturate for more than one week. I have felt it passing through my own veins over my shin bones after my return to England from New York on a periodical visit.

In conclusion, and to confirm the practical results already achieved, slow decompression will largely eliminate troubles in caisson works, and it is confirmed in my experience, and has been for years, that stage decompression is more effective than a continuous gradual fall in pressure, and it is fortunate that this method, due to the use of more than one air-lock and diaphragm, in tunnels at least, is the one most likely to arise in practice. In deep caissons for bridge work, however, it is not nearly so easy to apply.

HOME INDUSTRIES.

Steamships and Safety.—Attention was recently directed in these Notes to the supply of boats on large passenger steamers, and it was pointed out that the law as it stands is inadequate to the legitimate requirements of the travelling public. Since then more than one large passenger steamer has been reported lost, and the list of these lost vessels is becoming a long one. It does not of course follow that because a steamer leaves port and is never heard of again blame properly attaches to anyone. A derelict, or a sunken rock, may send a ship to the bottom and leave no trace of the disaster. Or she may turn over in a heavy gale and go down. The Board of Trade inquiry upon the loss of the "Waratah" has arrived at the conclusion that this is what happened to that vessel, but there is a growing opinion that ships are less safe than they used to be, and that the Board of Trade Regulations imperfectly protect the passenger. Take the case of the "Waratah." It was alleged by many witnesses at the inquiry, and was the opinion of many persons who had travelled in her but were not called, that she was top-heavy. The Court has rejected that view, and it must therefore be assumed that it is not warranted by the facts. But it will not be disputed that the "Waratah," like many of the other new passenger ships, was in appearance—at least in the eyes of the layman, if not of the seaman—top-heavy, and that of late years construction has taken the shape of deck upon deck in a way that would have been considered dangerous in other days. It may be said that the Board of Trade Inspector would not pass a ship whose stability was not assured, but the President of the Board of Trade has recently admitted that he lacks the necessary powers for effective intervention. Again, upon the question of boats. The theory of the Board of Trade is that every vessel should carry enough boats to take off the whole of the passengers and crew she is authorised to carry. Is that done? Take a mammoth liner with passengers and crew amounting to 2,000 or 3,000 souls. At most she would not have more than sixteen life-boats, carrying, say, sixty each, or in all under 1,000. There is no regulation of the Board of Trade requiring a vessel to carry more than this number, a number that would have been enough twenty years ago, when the regulation was passed, but is very far from adequate as regards the larger liners of to-day. It will be said that in addition to her life-boats, the vessel may have collapsible boats and rafts, but sailors have no faith in these auxiliaries. It is urged again by builders that nowadays the great liner is so built as to be unsinkable, and therefore the question of the sufficiency of boats ceases to be important so far as they are concerned. But it has yet to be proved that any vessel on the water is unsinkable, whilst it is known that a few months ago one of these "unsinkable" steamers went down so quickly that there was hardly time to get out the boats. It is true that although the maximum number of boats required by the regulations is admittedly insufficient for the very large liners now running, the Board of Trade officials insist upon certain additions being made to the boat accommodation over and above the maximum named in the regulations, but this at best is not a satisfactory substitute for the specific requirements of the regulations. Again, owing to the fierce stress of competition, the stowage of steamers is much less carefully attended to than it used to be, with the result that the steamer often goes to sea in a condition that almost invites disaster. The shipowners do their best to fulfil all legitimate and reasonable requirements, but they have many interests to consider—not least the demand of the travelling public for luxurious accommodation never dreamed of in other times—and many of them would welcome a Board of Trade inquiry into the three crucial matters referred to in this Note: (1) construction; (2) boats; (3) stowage.

Mill Loans and Income-Tax.—An interview has been arranged between certain Lancashire members and the Chancellor of the Exchequer on the subject of the reclaiming of income-tax on the interest paid by spinning mills on their loan capital. These loans are often used as a way of investing small savings, so that a mill's loans may be in a great number of amounts of £50 or £100. In inviting these loans, 4 per cent. interest has been promised, free of income-tax. But the money thus paid has in the regular course paid tax, which has been

reclaimed by those whose incomes were low enough to give them the right to reclaim. The Board of Inland Revenue recently decided that in future these claims for repayment will not be allowed, but representations from the representatives of those interested have induced the Board so far to modify the position they have taken up as to sanction the continuance of those claims in respect of interest paid for periods ending not later than September 30th next, the object of the concession being to give spinning companies time to make fresh arrangements with their lenders. It is understood that the Board hold strongly that the claims are not justified by the strict letter of the law.

Wood-Pulp as a Textile Material.—The possibilities of wood-pulp as a textile material have been brought to the front by Mr. Herbert Partington's statement. In Germany and the United States "paper yarn" has long since passed the experimental stage. At first regarded as a mere curiosity, it was quickly found that yarn could be manufactured from wood fibre more cheaply than from shoddy or cotton waste. The cellulose is cut into flat strips of varying width and thickness, and spun on specially-constructed machines, either alone or with the addition of a fine cotton thread. The cloth is strong, flexible, and serviceable, and does not ignite easily. It also takes dyes well. Tapestries, curtains, carpets, druggets, towellings, laces, and cellular underclothing are amongst the products manufactured from the new yarn. Mr. Partington mentions a mill in the Midlands which is spinning some 2,000 tons of pulp-yarn yearly, and one mill in Saxony which was recently turning out twenty tons a day. In Saxony the labour cost of producing one kilo (2·2 lbs.) of the yarn is about a third of a penny.

The Outlook for Rubber.—There has been a steady rise in the price of rubber during the last week or two, and the facts would seem to point to the maintenance of high prices. At a meeting of one of the leading rubber companies, held a few days ago, the chairman gave some interesting figures as to the statistical position. Taking 300 lbs. per acre as a fair estimate of the average production throughout the Middle East, and the present area under cultivated rubber at approximately about 730,000 acres, divided roughly into 370,000 acres in the Malay States, 180,000 acres in Ceylon, 130,000 acres in Java and Sumatra, and 50,000 acres in South India, Borneo, etc., he pointed out that this acreage, if properly kept up, is capable of producing, when in full bearing, about 100,000 tons of rubber per annum. But of course this maximum would not be reached, since it implies the highest possible cultivation and first-rate management throughout. Last year there was got from the Middle East about 8,000 tons of rubber. This year, Mr. Lampard estimates the available supply at 15,000 tons of rubber; next year about 25,000 tons, in 1913 about 45,000 tons, in 1914 about 70,000 tons, and in 1915 about 100,000 tons. Mr. Lampard's estimate of the consumption for 1909-10 is 100,000 tons, of which South America supplied 40,000 tons, the Middle East 8,000 tons, and the remainder of the world 52,000 tons. The ratio of increase in the consumption of rubber during the last few years has exceeded 10 per cent., and basing the calculation on this, and taking the world's consumption to-day at 100,000 tons, in 1912 the world will require 110,000 tons, in 1913 121,000 tons, in 1914 133,000 tons, and in 1915 146,000 tons, and the proportion of this amount possible to be produced by the Middle East Mr. Lampard puts at 100,000 tons in 1915. It will probably be a good deal less, but assuming that it amounts to 100,000 tons, there will still be a very large amount of rubber required by the world. It seems, then, safe to assume that high prices for rubber will be maintained for some years to come, and it must be remembered that if the price fell temporarily, it would at once check the supply of the wild collected rubber, and the price would then automatically rise again. If Mr. Lampard is right, cultivated rubber can be produced at a very much lower price in the Middle East than that at which it can be collected outside of it.

Brewery Stocks. — The investing public seem inclined to think better of the debentures and preference-stocks of English brewery companies than they have done for some time past. Notwithstanding a tendency to inflation, the securities of these companies, when first offered to the public, were viewed with favour, and they became a favourite form of security. For the most part, and for many years, the dividends paid confirmed the good opinion originally entertained. Then came a change, due to several causes. Unwise competition among the brewery companies for the acquisition of licensed properties led to heavy losses. A gradual change in the drinking habits of the community did not improve matters, and fears of legislative interference with the industry, culminating in a proposal that all licences should revert to the State in an average period of 11½ years, intensified the uneasiness of investors. It is true that this proposal did not become law, but the imposition of heavy licence duties was the alternative, and there was the fear of further legislation inimical to the brewing interest. This fear has now been lessened by the promise of the Chancellor of the Exchequer that in the new Finance Bill allowances will be made for the reduction in assessable value, and that assessment value shall be the basis of future taxation. The result is a rise in brewery stocks, and in some instances these debenture stocks stood at a large discount. Considerable purchases have been made on behalf of the companies concerned, with a view to improving the general position of the undertaking by the extinction of such debentures. The rise in quotations for brewery debenture stocks and preference shares which has occurred this year ranges from ½ per cent. to 8 per cent., and the buying appears to be of an investment character. The debenture stocks of

leading brewery companies are amply secured, and the present rise in this description of brewery securities is in most cases justified, for the fall had gone too far, but investors will do well to remember that the brewery companies have still to reckon with a shrinkage in the demand for their products, and the possibility of further hostile legislation.
